You create a transparent monitor to monitor the health of upstream devices, such as routers. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the router is UP but one of the next hop devices from that router is down, the appliance includes the router while performing load balancing and forwards the packet to the router. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the router) are down, the service is marked as DOWN and the router is not included when the appliance performs link load balancing.

To create a transparent monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> <type> -destIP <ip_addr|*> -transparent
   YES

show lb monitor [<monitorName>]
```

Example:

```
add lb monitor monitor-1 PING -destIP 10.10.10.11 -transparent YES
> show lb monitor monitor-1
1)   Name.......: monitor-1  Type......:      PING   State....:
   ENABLED
Standard parameters:
  Interval.........:            5 sec   Retries..........:
                  3
  Response timeout.:            2 sec   Down time.........:
     30 sec
  Reverse..........:               NO   Transparent.......:
                YES
  Secure...........:               NO   LRTM..............:
     ENABLED
  Action...........:   Not applicable   Deviation.........:
     0 sec
  Destination IP...:      10.10.10.11
  Destination port.:    Bound service
  Iptunnel.........:               NO
  TOS..............:               NO   TOS ID...........:
                   0
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
14   SNMP Alert Retries:               0     Success Retries..:
                        1
15   Failure Retries..:                0
```

To create a transparent monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors and configure a transparent monitor.

To create a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the Monitors pane, click Add.
3. In the Create Monitor dialog box, set the following parameters:
   - Name*
   - Type*
   - Destination IP
   - Transparent

   *A required parameter
4. Click Create, and then click Close.
5. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed in the Details pane are correct.

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. On the **Monitors** tab, under **Available**, select the monitor that you want to bind to the service, and then click **Add**.

To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
1 bind lb monitor <monitorName> <serviceName>
2
3 show service <name>
```

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

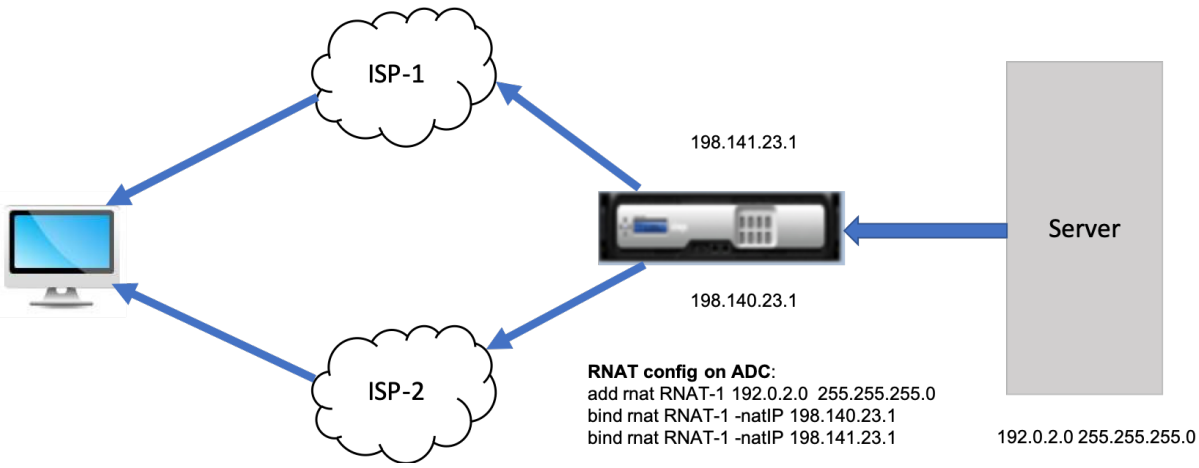
```
bind lb monitor monitor-HTTP-1 ISP1R_svc_any
 Done
> show service ISP1R_svc_any
        ISP1R_svc_any (10.10.10.254:*) - ANY
        State: UP
        Last state change was at Thu Sep  2 10:51:07 2010
        Time since last state change: 0 days, 18:41:55.130
        Server Name: 10.10.10.254
        Server ID : 0   Monitor Threshold : 0
        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
        Use Source IP: NO
        Client Keepalive(CKA): NO
        Access Down Service: NO
        TCP Buffering(TCPB): YES
        HTTP Compression(CMP): NO
        Idle timeout: Client: 120 sec   Server: 120 sec
        Client IP: DISABLED
        Cacheable: NO
        SC: OFF
        SP: OFF
        Down state flush: ENABLED

1)      Monitor Name: monitor-HTTP-1
                State: UP  Weight: 1
                Probes: 1256       Failed [Total: 0 Current: 0]
                Last response: Success - ICMP echo reply received.
                Response Time: 1.322 millisec
 Done
```

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select a service to which you want to bind a monitor, and then click Open.
3. In the Configure Service dialog box, on the Monitors tab, under Available, select the monitor that you want to bind to the service, and then click Add.
4. Click OK.
5. In the Services pane, select the service that you just configured and verify that the settings displayed in the Details pane are correct.

Configure RNAT with LLB



September 14, 2021

You can configure an LLB setup for reverse network address translation (RNAT) for outbound traffic. It

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

ensures that the return network traffic for a specific flow is routed through the same path. First configure basic LLB, as described in Configuring a Basic LLB Setup, and then configure RNAT as described in Configure RNAT. Then enable "use subnet IP (USNIP)"mode.

In the following diagram, the Citrix ADC appliance uses LLB to route outbound traffic to different links. During the RNAT operation, the ADC appliance replaces the source IP addresses of the outbound traffic with the public NAT IP address (198.141.23.1) to route the traffic through ISP-1. Similarly, the ADC appliance replaces the source IP addresses with 198.140.23.1 to route the traffic through ISP-2.

To add SNIPs for ISP routers by using the CLI

At the command prompt, type:

```
add NS IP <subnet of first ISP in the IP router> <subnet mask> -type
    SNIP

add NS IP <subnet of second ISP in the IP router> <subnet mask> -type
    SNIP
```

Example:

```
add ns ip 198.140.23.1 255.255.255.0 -type snip

add ns ip 198.141.23.1 255.255.255.0 -type snip
```

To configure RNAT by using the CLI

At the command prompt, type:

```
add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))

bind rnat <name> <natIP>@ ...

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
show rnat <name>
```

Example:

```
add rnat RNAT-1 192.0.2.0 255.255.255.0
bind rnat RNAT-1 -natIP 198.140.23.1
bind rnat RNAT-1 -natIP 198.141.23.1

> show rnat RNAT-1
    1) RNAT Name: RNAT-1     Network: 192.0.2.0      Netmask:
       255.255.255.0     Traffic Domain: 0
        UseProxyPort: ENABLED

        NatIP: 198.140.23.1
        NatIP: 198.141.23.1
```

To configure RNAT by using the GUI

1. Navigate to **System** > **Network** > **NATs**.
2. On the **RNAT** tab, click **Configure RNAT**.
3. Specify the network on which to perform RNAT.

> **Note**
>
> You can also configure RNAT by using Access Control Lists (ACLs). Refer Configuring RNAT for details.

To enable Use Subnet IP mode by using the CLI

At the command prompt, type:

```
enable ns mode USNIP

show ns mode
```

Example:

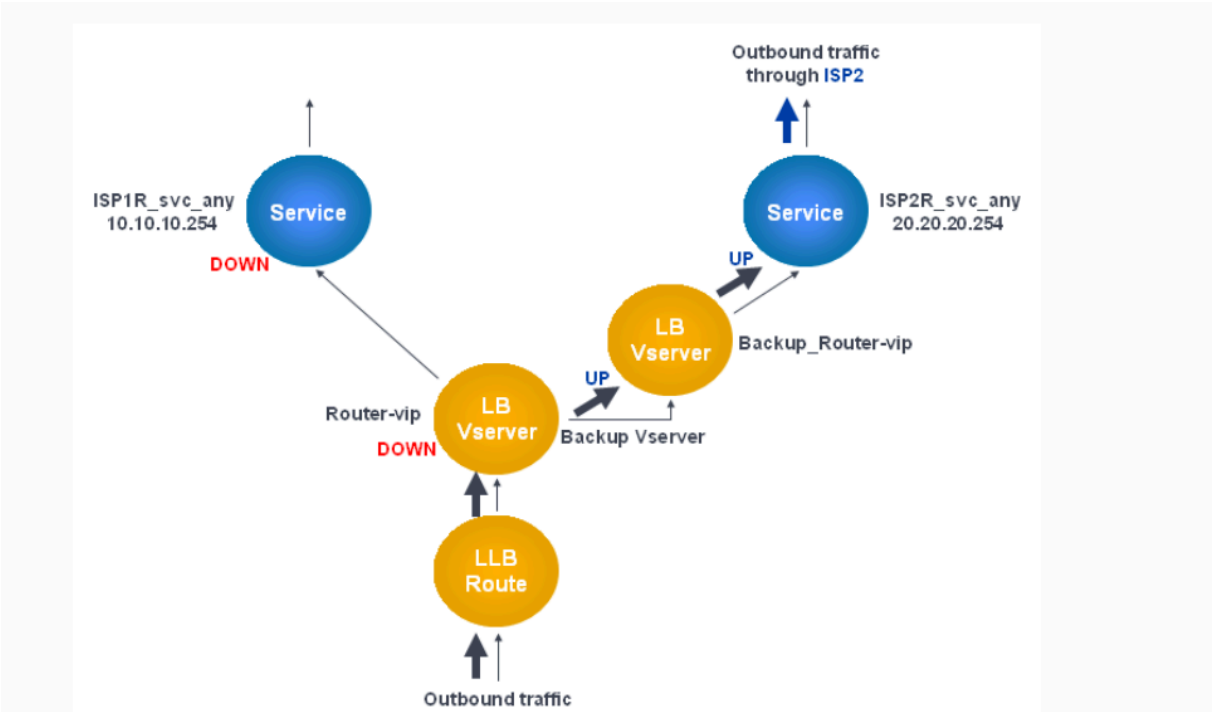
```
enable ns mode USNIP

show ns mode
        Mode                            Acronym             Status
        -------                         -------             ------
 1)     Fast Ramp                       FR                  ON
 2)     ….
 8)     Use Subnet IP                   USNIP               ON
 9)     …
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable Use Subnet IP mode by using the GUI

1. Navigate to **System** > **Settings** and, under **Modes and Features**, click **Configure Modes**.
2. In the **Configure Modes** dialog box, select **Use Subnet IP**, and then click **OK**.



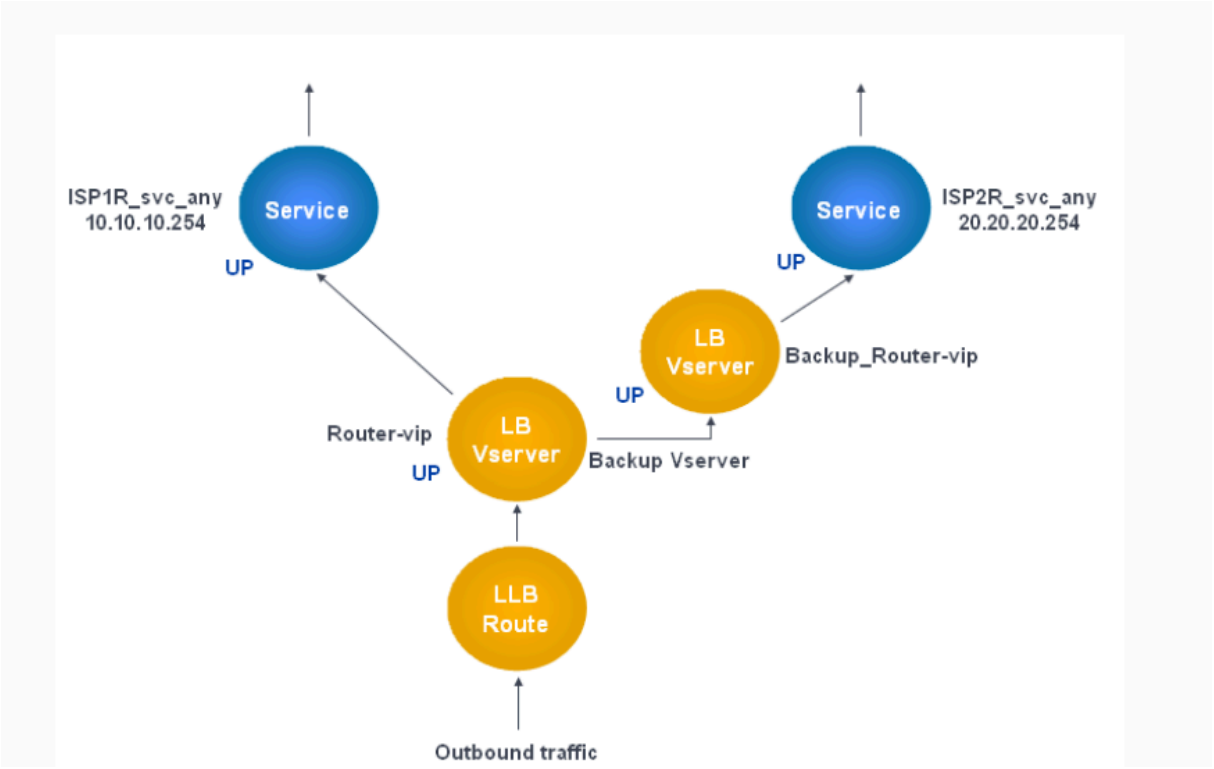
Configure a backup route

September 14, 2021

To prevent disruption in services when the primary route is down, you can configure a backup route. Once the backup route is configured, the Citrix ADC appliance automatically uses it when the primary route fails. First create a primary virtual server as described in Configuring an LLB Virtual Server and Binding a Service. To configure a backup route, create a secondary virtual server similar to a primary virtual server and then designate this virtual server as a backup virtual server (route).

In the following diagram, **Router-vip** is the primary virtual server, and **Backup_Router-vip** is the secondary virtual server designated as the backup virtual server.

Figure 1. Backup Route Setup



Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

By default, all traffic is sent through the primary route. However, when the primary route fails, all traffic is diverted to the backup route as shown in the following diagram.

Figure 2. Back up Routing in Operation

Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

To set the secondary virtual server as the backup virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -backupVserver <string>
```

Example:

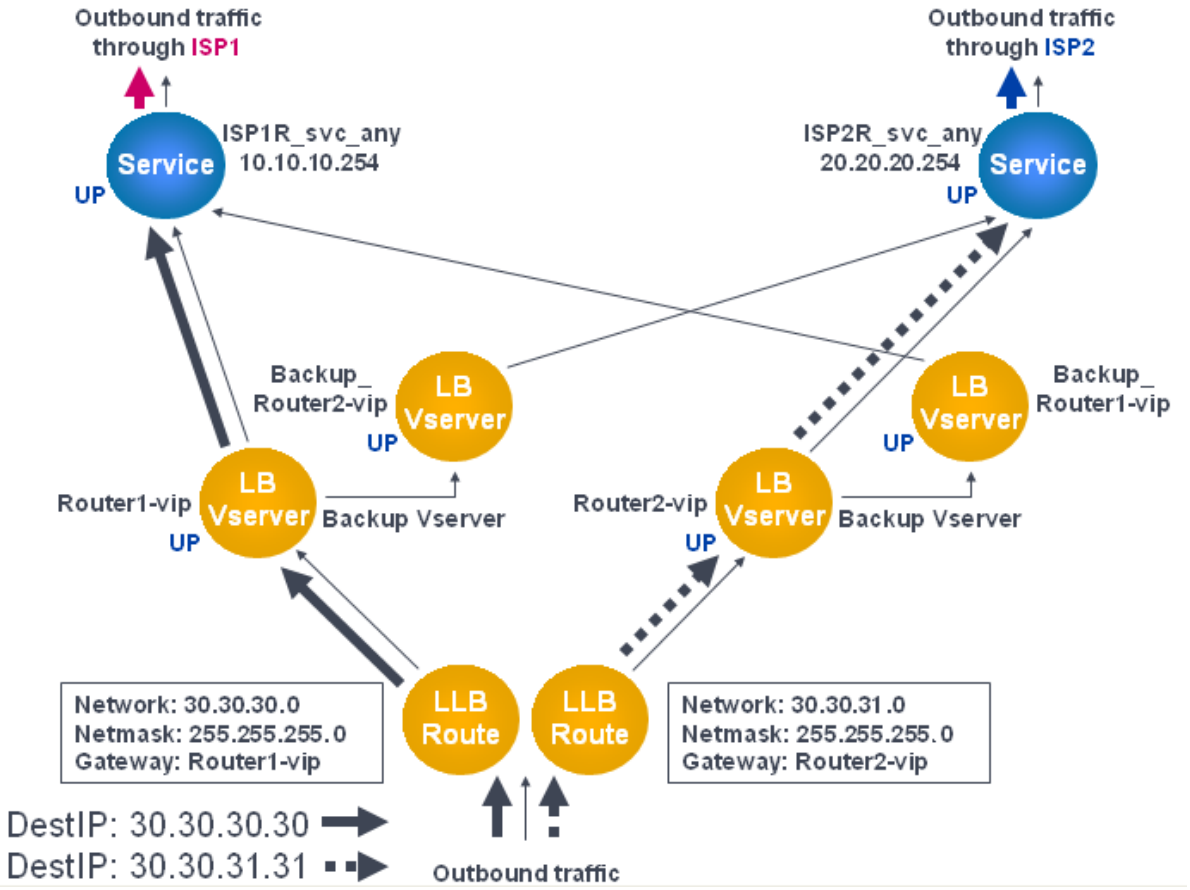
```
set lb vserver Router-vip -backupVServer Backup_Router-vip
> show lb vserver Router-vip
        Router-vip (0.0.0.0:0) - ANY    Type: ADDRESS
        State: UP
        Last state change was at Fri Sep  3 04:46:48 2010
        Time since last state change: 0 days, 03:09:45.600
        Effective State: UP
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
10          Disable Primary Vserver On Down : DISABLED
11          No. of Bound Services :  1 (Total)       1 (Active)
12          Configured Method: ROUNDROBIN
13          Mode: IP
14          Persistence: DESTIP     Persistence Mask: 255.255.255.255
                      Persistence v6MaskLength: 128   Persistence Timeout: 2
                min
15          Backup: Router2-vip
16          Connection Failover: DISABLED
17   Done
```

To set the secondary virtual server as the backup virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the secondary virtual server for which you want to configure the backup virtual server.
2. In the **Load Balancing Virtual Server** dialog box, under **Advanced**, select **Protection**.
3. In the **Backup Virtual Server** drop-down list, select the secondary backup virtual server, and then click **OK**.



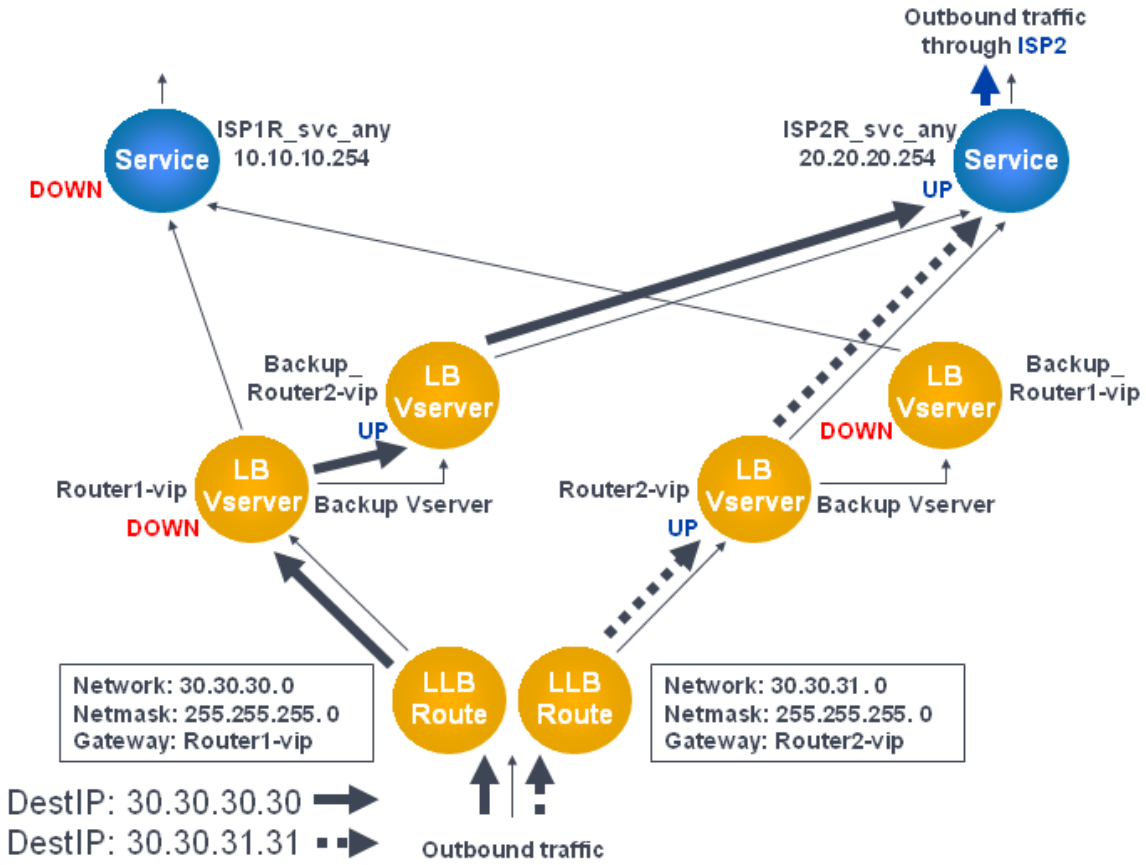
Resilient LLB deployment scenario

September 14, 2021

In the following diagram, there are two networks: 30.30.30.0 and 30.30.31.0. Link load balancing is configured based on the destination IP address. Two routes are configured with gateways **Router1-vip** and **Router2-vip**, respectively. **Router1-vip** is configured as a backup to **Router2-vip** and the opposite way. All traffic with the destination IP specified as 30.30.30.30 is sent through **Router1-vip** and traffic with the destination IP specified as 30.30.31.31 is sent through **Router2-vip**.

Figure 1. Resilient LLB Deployment Setup

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

However, if any one of the gateways (**Router1-vip** or **Router2-vip**) is DOWN, traffic is routed through the backup router. In the following diagram, **Router1-vip** for ISP1 is DOWN, so all traffic with the destination IP specified as 30.30.30.30 is also sent through ISP2.

Figure 2. Resilient LLB Deployment Scenario

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

Monitor an LLB setup

September 14, 2021

After the configuration is up and running, you can view the statistics for each service and virtual server to check for possible problems.

View the statistics of a virtual server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers. You can also specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

Display virtual server statistics by using the CLI

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC, or for a single virtual server, at the command prompt, type:

```
stat lb vserver -detail] [<name>]
```

Example:

```
stat lb vserver -detail
Virtual Server(s) Summary
                        vsvrIP  port     Protocol        State    Req/s
                             Hits/s
One                          *    80         HTTP           UP      5/s
          0/s
Two                          *     0          TCP         DOWN      0/s
          0/s
Three                        *  2598          TCP         DOWN      0/s
          0/s
dnsVirtualNS    10.102.29.90    53          DNS         DOWN      0/s
          0/s
BRVSERV            10.10.1.1    80         HTTP         DOWN      0/s
          0/s
LBVIP           10.102.29.66    80         HTTP           UP      0/s
          0/s
 Done
```

Display virtual server statistics by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers > Statistics**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

View the statistics of a service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

View the statistics of a service by using the CLI

At the command prompt, type:

```
stat service <name>
```

Example:

```
stat service Service-HTTP-1
```

View the statistics of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services > Statistics**.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

Load Balancing

September 14, 2021

The load balancing feature distributes user requests for webpages and other protected applications across multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages and ensuring that users can access your protected applications. Load balancing also provides fault tolerance. When one server that hosts a protected application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

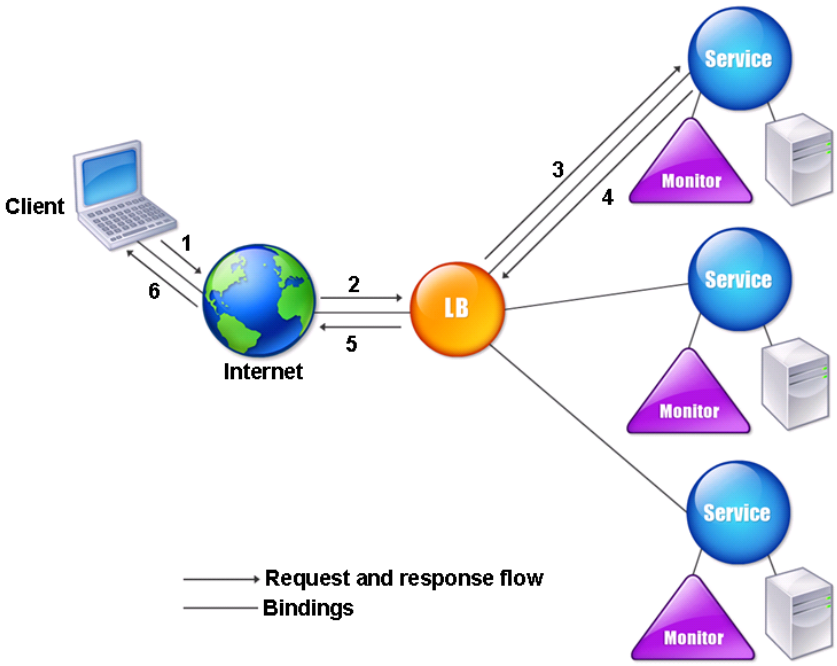
You can configure the load balancing feature to;

- Distribute all requests for a specific protected website, application, or resource between two or more identically configured servers.
- Use any of several different algorithms to determine which server must receive each incoming user request, basing the decision on different factors, such as which server has the fewest current user connections or which server has the lightest load.

The load balancing feature is a core feature of the Citrix ADC appliance. Most users first set up a working basic configuration and then customize various settings, including persistence for connections. In addition, you can configure features for protecting the configuration against failure, managing client traffic, managing and monitoring servers, and managing a large scale deployment.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

How load balancing works



August 16, 2023

In a basic load balancing setup, clients send their requests to the IP address of a virtual server configured on the Citrix ADC appliance. The virtual server distributes them to the load-balanced application servers according to a preset pattern, called the load balancing algorithm. Sometimes, you might want to assign the load balancing virtual server a wildcard address instead of a specific IP address. For instructions about specifying a global HTTP port on the appliance, see **Global HTTP Ports**.

Load balancing basics

A load balancing setup includes a load-balancing virtual server and multiple load-balanced application servers. The virtual server receives incoming client requests, uses the load balancing algorithm to select an application server, and forwards the requests to the selected application server. The following conceptual drawing illustrates a typical load balancing deployment. Another variation involves assigning a global HTTP port.

Figure 1. Load Balancing Architecture

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

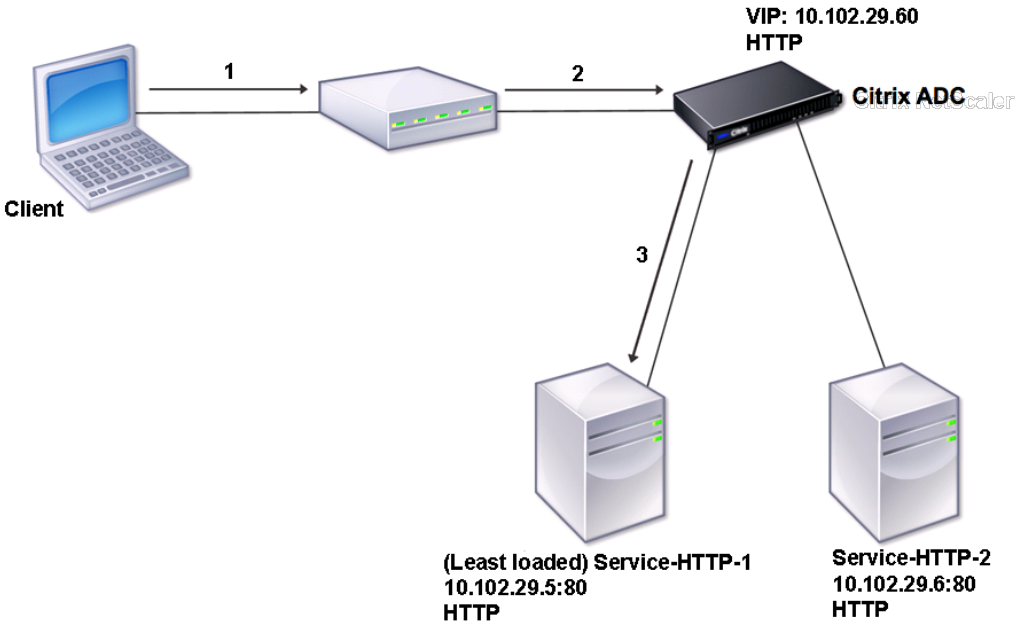
The load balancing virtual server can use several algorithms (or methods) to determine how to distribute load among the load-balanced servers that it manages. The default load balancing method is the least connection method, in which the Citrix ADC appliance forwards each incoming client connection to whichever load-balanced application server currently has the fewest active user connections.

The entities that you configure in a typical Citrix ADC load balancing setup are:

- **Load balancing virtual server.** The IP address, port, and protocol combination to which a client sends connection requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the LAN or WAN, the VIP is usually a private (ICANN non-routable) IP address.
- **Service.** The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a load balancing virtual server.
- **Server object.** A virtual entity that enables you to assign a name to a physical server instead of identifying the server by its IP address. If you create a server object, you can specify its name instead of the server's IP address when you create a service. Otherwise, you must specify the server's IP address when you create a service, and the IP address becomes the name of the server.
- **Monitor.** An entity on the Citrix ADC appliance that tracks a service and ensures that it is operating correctly. The monitor periodically probes (or performs a health check on) each service to which you assign it. If the service does not respond within the time specified by the time-out, and a specified number of health checks fail, that service is marked DOWN. The Citrix ADC appliance then skips that service when performing load balancing, until the issues that caused the service to quit responding are fixed.

The virtual server, services, and load balanced application servers in a load balancing setup can use either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) IP addresses. You can mix IPv4 and IPv6 addresses in a single load balancing setup.

For variations in the load balancing setup, see the following use cases:



- Configuring Load Balancing in Direct Server Return Mode
- Configuring LINUX Servers in DSR Mode
- Configuring DSR Mode When Using TOS
- Configuring Load Balancing in DSR Mode by Using IP Over IP
- Configuring Load Balancing in One-arm Mode
- Configuring Load Balancing in the Inline Mode
- Load Balancing of Intrusion Detection System Servers
- Load balance remote desktop protocol servers

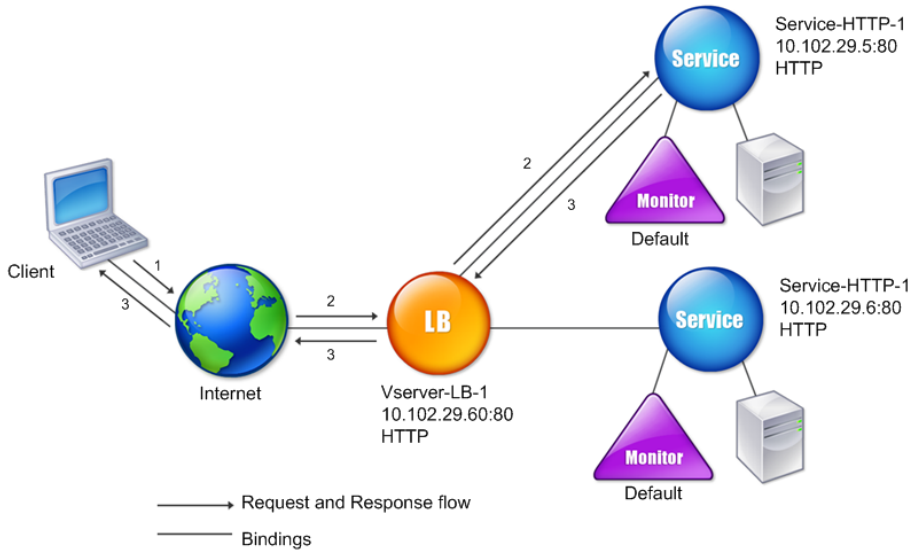
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Understanding the topology

In a load balancing setup, the load balancing server is logically located between the client and the server farm, and manages traffic flow to the servers in the server farm. On the Citrix ADC appliance, the application servers are represented by virtual entities called services. The following diagram shows the topology of a basic load balancing configuration.

Figure 2. Basic Load Balancing Topology

In the diagram, load balancing is used to manage traffic flow to the servers. The virtual server selects the service and assigns it to serve client requests. Consider a scenario where the services Service-HTTP-1 and Service-HTTP-2 are created and bound to the virtual server named Vserver-LB-1. Vserver-LB-1 forwards the client request to either Service-HTTP-1 or Service-HTTP-2. The Citrix ADC appliance uses the least connection load balancing method to select the service for each request. The following table lists the names and values of the basic entities that must be configured on the appliance.



Entity	Name	IPAddress	Port	Protocol
Virtual server	Vserver-LB-1	10.102.29.60	80	HTTP
Services	Service-HTTP-1	10.102.29.5	80	HTTP

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity	Name	IPAddress	Port	Protocol
		Service-HTTP-2	10.102.29.6	80
Monitors	Default	None	None	None

The following diagram shows the load balancing sample values and mandatory parameters that are described in the preceding table.

Figure 3. Load Balancing Entity Model

Use of wildcards instead of IP addresses and ports

Sometimes you might need to use a wildcard for the IP address or the port of a virtual server or for the port of a service. The following cases might require using a wildcard:

- If the Citrix ADC appliance is configured as a transparent pass through, which must accept all traffic that is sent to it regardless of the IP or port to which it is sent.
- If one or more services listen on ports that are not well known.
- If one or more services, over time, change the ports that they listen on.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- If you reach the limit for the number of IP addresses and ports that you can configure on a single Citrix ADC appliance.
- If you want to create virtual servers that listen for all traffic on a specific virtual LAN.

When a wildcard-configured virtual server or service receives traffic, the Citrix ADC appliance determines the actual IP address or port and creates records for the service and associated load balanced application server. These dynamically created records are called dynamically learned server and service records.

For example, a firewall load balancing configuration can use wildcards for both the IP address and port. If you bind a wildcard TCP service to this type of load balancing virtual server, the virtual server receives and processes all TCP traffic that does not match any other service or virtual server.

The following table describes some of the different types of wildcard configurations and when each must be used.

IP	Port	Protocol	Description
*	*	TCP	A general wildcard virtual server that accepts traffic sent to any IP address and port on the Citrix ADC appliance. When using a wildcard virtual server, the appliance dynamically learns the IP and port of each service and creates the necessary records as it processes traffic.
*	*	TCP	A firewall load balancing virtual server. You can bind firewall services to this virtual server, and the Citrix ADC appliance passes traffic through the firewall to the destination.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

IP	Port	Protocol	Description
IP Address	*	TCP, UDP, and ANY	A virtual server that accepts all traffic that is sent to the specified IP address, regardless of the port. You must explicitly bind to this type of virtual server the services to which it will redirect traffic. It does not learn them dynamically.
*	port	SSL, SSL_TCP	A virtual server that accepts all traffic sent to any IP address on a specific port. Used for global transparent SSL offloading. All SSL, HTTP, and TCP processing that usually is performed for a service of the same protocol type is applied to traffic that is directed to this specific port. The appliance uses the port to dynamically learn the IP of the service it must use. If –cleartext is not specified, the Citrix ADC appliance uses end-to-end SSL.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

IP	Port	Protocol	Description
*	port	Not applicable	All other virtual servers that can accept traffic to the port. You do not bind services to these virtual servers. The Citrix ADC appliance learns them dynamically.

Note: If you have configured your Citrix ADC appliance as a transparent pass through that uses global (wildcard) ports, you might want to turn on Edge mode.
For more information, see "Configuring Edge Mode."

The Citrix ADC appliance attempts to locate virtual servers and services by first attempting an exact match. If none is found, it continues to search for a match based on wildcards, in the following order:

1. Specific IP address and specific port number
2. Specific IP address and a * (wildcard) port
3. • (wildcard) IP address and a specific port
4. • (wildcard) IP address and a * (wildcard) port

If the appliance is unable to select a virtual server by IP address or port number, it searches for a virtual server based on the protocol used in the request, in the following order:

1. HTTP
2. TCP
3. ANY

Configuring global HTTP ports

You do not configure services or virtual servers for a global HTTP port. Instead, you configure a specific port by using the set ns param command. After configuring this port, the Citrix ADC appliance accepts all traffic that matches the port number, and processes it as HTTP traffic, dynamically learning and creating services for that traffic.

You can configure more than one port number as a global HTTP port. If you are specifying more than one port number in a single set ns param command, separate the port numbers by a single white space. If one or more ports have already been specified as global HTTP ports, and you want to add

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

one or more ports without removing the ports that are currently configured, you must specify all the port numbers, current and new, in the command. Before you add port numbers, use the show ns param command to view the ports that are currently configured.

To configure a global HTTP port by using the command line interface

At the command prompt, type the following commands to configure a global HTTP port and verify the configuration:

```
set ns param  – httpPort <port>

show ns param
```

Example 1: Configuring a port as a global HTTP port In this example, port 80 is configured as a global HTTP port.

```
set ns param -httpPort 80
Done
show ns param
         Global configuration settings:
                          HTTP port(s): 80
                       Max connections: 0
            Max requests per connection: 0
                    Client IP insertion: DISABLED
                         Cookie version: 0
         Persistence Cookie Secure Flag: ENABLED
         ...
         ...
```

Example 2: Adding ports when one or more global HTTP ports are already configured** In this example, port 8888 is added to the global HTTP port list. Port 80 is already configured as a global HTTP port.

```
> show ns param
        Global configuration settings:
                          HTTP port(s): 80
                       Max connections: 0
            Max requests per connection: 0
                    Client IP insertion: DISABLED
                         Cookie version: 0
        Persistence Cookie Secure Flag: ENABLED
                          Min Path MTU: 576
        ...
        ...
 Done
> set ns param -httpPort 80 8888
 Done
```

```
>  show ns param

        Global configuration settings:
                            HTTP port(s): 80,8888
                        Max connections: 0
           Max requests per connection: 0
                    Client IP insertion: DISABLED
                         Cookie version: 0
        Persistence Cookie Secure Flag: ENABLED
                            Min Path MTU: 576

        ...
        ...
 Done
>
```

To configure a global HTTP port by using the configuration utility

1. Navigate to **System > Settings > Change HTTP Parameters**, and then add an HTTP port number.

Set up basic load balancing

March 20, 2024

Before configuring your initial load balancing setup, enable the load balancing feature. Then begin by creating at least one service for each server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server, and bind each service to the virtual server. That completes the initial setup. Before proceeding with further configuration, verify your configuration to make sure that each element was configured properly and is operating as expected.

Enable Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the CLI

At the command prompt, type the following command to enable load balancing and verify the configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- enable ns feature LB
- show ns feature

Example

```
> enable ns feature LoadBalancing

 Done

> show ns feature

        Feature                         Acronym              Status

        -------                         -------              ------

 1)     Web Logging                     WL                   OFF

 2)     Surge Protection                SP                   ON

 3) Load Balancing LB ON

 .

 .

 .

 24)    NetScaler Push                  push                 OFF

 Done
```

To enable load balancing by using the GUI

Navigate to **System** > **Settings** and, in **Configure Basic Features**, select **Load Balancing**.

Configure a Server Object

Create an entry for your server on the Citrix ADC appliance. The Citrix ADC appliance supports IP address based servers and domain-based servers. If you create an IP address based server, you can specify the name of the server instead of its IP address when you create a service. For information about setting up DNS for a domain-based server, see Domain Name System.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To create a server object by using the CLI

At the command prompt, type:

```
add server `<name>`@ `<IPAddress>`@ | `<domain>`
```

Example for adding IP address-based name server:

```
add server web_serv 10.102.27.150
```

Example for adding domain-based server:

```
add server web_serv test.com
```

To create a server object by using the GUI

Navigate to **Traffic Management** > **Load Balancing** > **Servers**, and add a server object.

Configure services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the Citrix ADC appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

When you create a service that uses UDP as the transport layer protocol, a ping monitor is automatically bound to the service. A ping monitor is the most basic of the built-in monitors. When you create a service that uses TCP as the transport layer protocol, a TCP_default monitor is automatically bound to the service. When you develop a strategy for managing your load balancing setup, you might decide to bind a different type of monitor, or multiple monitors, to the service.

Create a service

Before you create a service, you need to understand the different service types and how each is used. The following list describes the types of services supported on the NetScaler appliance.

- **HTTP**

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Used for load-balanced servers that accept HTTP traffic, such as standard websites and web applications. The HTTP service type enables the NetScaler appliance to provide compression, content filtering, caching, and client keep-alive support for your Layer 7 web servers. This service type also supports virtual server IP port insertion, redirect port rewriting, Web 2.0 Push, and URL redirection support.

Because HTTP is a TCP-based application protocol, you can also use the TCP service type for web servers. If you do so, however, the NetScaler appliance is able to perform only Layer 4 load balancing. It cannot provide any of the Layer 7 supports described earlier.

- **SSL**

  Used for servers that accept HTTPS traffic, such as ecommerce websites and shopping cart applications. The SSL service type enables the NetScaler appliance to encrypt and decrypt SSL traffic (perform SSL offloading) for your secure web applications. It also supports HTTP persistence, content switching, rewrite, virtual server IP port insertion, Web 2.0 Push, and URL redirection.

  You can also use the SSL_BRIDGE, SSL_TCP, or TCP service types. If you do so, however, the appliance performs only Layer 4 load balancing. It cannot provide SSL offloading or any of the Layer 7 supports described.

- **FTP**

  Used for servers that accept FTP traffic. The FTP service type enables the NetScaler appliance to support specific details of the FTP protocol.

  You can also use TCP or ANY service types for FTP servers.

- **TCP**

  Used for servers that accept many different types of TCP traffic, or that accept a type of TCP traffic for which a more specific type of service is not available.

  You can also use the ANY service type for these servers.

- **SSL_TCP**

  Used for servers that accept non-HTTP-based SSL traffic, to support SSL offloading.

  You can also use the TCP service type for these services. If you do so, the NetScaler appliance performs both the Layer 4 load balancing and SSL offloading.

- **UDP**

  Used for servers that accept UDP traffic. You can also use the ANY service type.

- **SSL_BRIDGE**

  Used for servers that accept SSL traffic when you do not want the NetScaler appliance to perform SSL offloading. Alternatively, you can use the SSL_TCP service type.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **NNTP**

  Used for servers that accept Network News Transfer Protocol (NNTP) traffic, typically Usenet sites.

- **DNS**

  Used for servers that accept DNS traffic, typically nameservers. With the DNS service type, the NetScaler appliance validates the packet format of each DNS request and response. It can also cache DNS responses. You can apply DNS policies to DNS services.

  You can also use the UDP service type for these services. If you do, however, the NetScaler appliance can only perform Layer 4 load balancing. It cannot provide support for DNS-specific features.

- **ANY**

  Used for servers that accept any type of TCP, UDP, or ICMP traffic. The ANY parameter is used primarily with firewall load balancing and link load balancing.

- **SIP-UDP**

  Used for servers that accept UDP-based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).

  You can also use the UDP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot provide support for SIP-specific features.

- **DNS-TCP**

  Used for servers that accept DNS traffic, where the NetScaler appliance acts as a proxy for TCP traffic sent to DNS servers. With services of the DNS-TCP service type, the NetScaler appliance validates the packet format of each DNS request and response and can cache DNS responses, as with the DNS service type.

  You can also use the TCP service type for these services. If you do, however, the NetScaler appliance only performs Layer 4 load balancing of external DNS name servers. It cannot provide support for any DNS-specific features.

- **RTSP**

  Used for servers that accept Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data. Select this type to support audio, video, and other types of streamed media.

  You can also use the TCP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot parse the RTSP stream or provide support for RTSPID persistence or RTSP NAT.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **DHCPRA**

  Used for servers that accept DHCP traffic. The DHCPRA service type can be used to relay DHCP requests and responses between VLANs.

- **DIAMETER**

  Used for load balancing Diameter traffic among multiple Diameter servers. Diameter uses message-based load balancing.

- **SSL_DIAMETER**

  Used for load balancing Diameter traffic over SSL.

  Services are designated as DISABLED until the NetScaler appliance connects to the associated load-balanced server and verifies that it is operational. At that point, the service is designated as ENABLED. Thereafter, the NetScaler appliance periodically monitors the status of the servers, and places any that fail to respond to monitoring probes (called health checks) back in the DISABLED state until they respond.

  > **Note:**
  >
  > You can create a range of services from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix/prefix. For example, service1, service2, and so on. From the GUI, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in an IPv6 address. From the command line, you can specify the range in any octet of the IP address.

- **QUIC**

  Used by load balancing servers that accept UDP based QUIC video traffic. The service enables the NetScaler appliance to optimize encrypted ABR video traffic over the UDP protocol.

To create a service by using the CLI

At the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>

add service Service-HTTP-1 192.0.2.5 HTTP 80
```

To create a service by using the GUI

1. Navigate to **Traffic Management**> **Load Balancing** > **Services**.
2. In the details pane, click **Add**.
3. In the Create Service dialog box, specify values for the following parameters:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Service Name—name
- Server—serverName
- Protocol—serviceType
- Port—port

4. Click **Create**, and then click **Close**. The service you created appears in the Services pane.

Creating a Virtual Server

After you create your services, you must create a virtual server to accept traffic for the load balanced websites, applications, or servers. Once load balancing is configured, users connect to the load-balanced website, application, or server through the virtual server's IP address or FQDN.

Note:

- Virtual server names prefixed with "app_"do not appear in the GUI though they are present in the ns.conf file and are displayed when you run the show command. However, virtual server names prefixed with "app"are displayed in the GUI.
- The virtual server is designated as DOWN until you bind the services that you created to it, and until the Citrix ADC appliance connects to those services and verifies that they are operational. Only then is the virtual server designated as UP.

To create a virtual server by using the CLI

At the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>

add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

To create a virtual server by using the GUI

Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and then create a virtual server.

Binding Services to the Virtual Server

Note: A service can be bound to a maximum of 500 virtual servers.

After you have created services and a virtual server, you must bind the services to the virtual server. Usually, services are bound to virtual servers of the same type, but you can bind certain types of services to certain different types of virtual servers, as shown below.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Virtual Server Type	Service Type	Comment
HTTP	SSL	You would normally bind an SSL service to an HTTP virtual server to do encryption.
SSL	HTTP	You would normally bind an HTTP service to an SSL virtual server to do SSL offloading.
SSL_TCP	TCP	You would normally bind a TCP service to an SSL_TCP virtual server to do SSL offloading for other TCP (SSL decryption without content awareness).

The state of the services bound to a virtual server determines the state of the virtual server: if all of the bound services are DOWN, the virtual server is marked DOWN, and if any of the bound services is UP or OUT OF SERVICE, the state of the virtual server is UP.

To bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

```
bind lb vserver <name> <serviceName>

bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind a service to a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management**> **Load Balancing** > **Virtual Servers**, and select a virtual server.
2. Click in the **Service** section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Verifying the Configuration

After finishing your basic configuration, you can view the properties of each service and load balancing virtual server in your load balancing setup to verify that each is configured correctly. After the configuration is up and running, you can view the statistics for each service and load balancing virtual server to check for possible problems.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Viewing the Properties of a Server Object

You can view properties such as the name, state, and IP address of any server object in your Citrix ADC appliance configuration.

To view the properties of server objects by using the command line interface At the command prompt, type:

```
show server <serverName>

show server server-1
```

To view the properties of server objects by using the GUI Navigate to **Traffic Management** > **Load Balancing** > **Servers**. The parameter values of the available servers appear in the details pane.

View the properties of a virtual server

You can view properties such as the name, state, effective state, IP address, port, protocol, method, and number of bound services for your virtual servers. If you have configured more than the basic load balancing settings, you can view the persistence settings for your virtual servers, any policies that are bound to them, and any cache redirection and content switching virtual servers that have been bound to the virtual servers.

To view the properties of a load balancing virtual server by using the CLI At the command prompt, type:

```
show lb vserver <name>

show lb vserver Vserver-LB-1
```

To view the properties of a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. In the details pane, click a virtual server to display its properties at the bottom of the details pane.
3. To view the cache redirection and content switching virtual servers that are bound to this virtual server, click **Show CS/CR Bindings**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

View the properties of a service

You can view the name, state, IP address, port, protocol, maximum client connection, maximum requests per connection, and server type of the configured services, and use this information to troubleshoot any mistake in the service configuration.

To view the properties of services by using the CLI At the command prompt, type:

```
show service <name>

show service Service-HTTP-1
```

To view the properties of services by using the GUI Navigate to **Traffic Management** > **Load Balancing** > **Services**. The details of the available services appear on the Services pane.

View the bindings of a service

You can view the list of virtual servers to which the service is bound. The binding information also provides the name, IP address, port, and state of the virtual servers to which the services are bound. You can use the binding information to troubleshoot any problem with binding the services to virtual servers.

To view the bindings of a service by using the CLI At the command prompt, type:

```
show service bindings <name>

show service bindings Service-HTTP-1
```

To view the bindings of a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. In the details pane, select the service whose binding information you want to view.
3. In the **Action** tab, click **Show Bindings**.

View the statistics of a virtual server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the CLI To display a summary of the statistics for all the virtual servers currently configured on the appliance, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [`<name>`]
```

Example:

```
stat lb vserver server-1
```

The following figure displays a sample statistic.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> stat lbvserver
[
Virtual Server(s) Summary

shar...es-lb          0.0.0.0     0         HTTP           UP      0/s

shar...nt-lb          0.0.0.0     0         HTTP           UP      0/s

shar...nt-lb          0.0.0.0     0         HTTP           UP      0/s

shar...nt-lb          0.0.0.0     0         HTTP           UP      0/s

shar...nt-lb          0.0.0.0     0         HTTP           UP      0/s

shar...nt-lb          0.0.0.0     0         HTTP           UP      0/s

shar...nt-lb          0.0.0.0     0         HTTP           UP      0/s

shar...ts-lb          0.0.0.0     0         HTTP           UP      0/s

shar...ns-lb          0.0.0.0     0         HTTP           UP      0/s

shar...as-lb          0.0.0.0     0         HTTP           UP      0/s

forward-vs            0.0.0.0     0          TCP         DOWN      0/s

tcpcs                 0.0.0.0     0          TCP         DOWN      0/s

test124               0.0.0.0     0          SSL         DOWN      0/s

testssl               0.0.0.0     0          SSL         DOWN      0/s
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To display virtual server statistics by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click **Statistics**.

View the statistics of a service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the CLI At the command prompt, type:

```
stat service <name>
```

Example:

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click **Statistics**. The statistics appear in a new window.

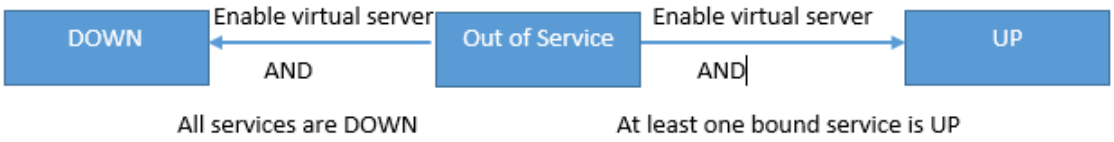
Load balance virtual server and service states

September 14, 2021

A load balancing virtual server that does not have a backup virtual server can take the following states, depending on the states of the services bound to it and whether it is administratively disabled:

- **UP**: At least one of the services bound to the virtual server is UP.
- **DOWN**: All the services bound to the virtual server are DOWN, or the load balancing feature is not enabled.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



- **Out of Service (OFS)**: If you administratively disable the virtual server, it enters the OFS state but its effective state is DOWN. Administrator can control the transitioning to the OFS state from the DOWN or UP state, or to the DOWN or UP state from the OFS state.

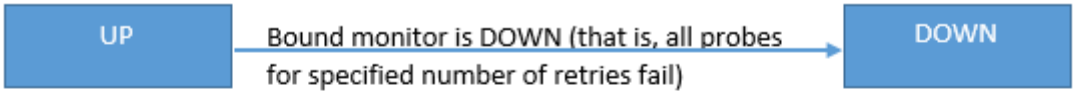
The state and effective state of a virtual server are the same if a backup virtual server is not configured. However, if a backup virtual server or a chain of backup virtual servers is configured, the effective state is derived from the states of the services that are bound to the primary virtual server and the backup virtual servers. If any of the backup virtual servers in the chain is UP, the effective state of the primary virtual server is UP, even if all the services bound to the primary virtual server are DOWN.

The following diagrams show the conditions under which a virtual server transitions from one state to another.

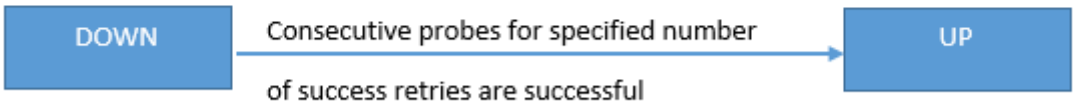
A service can take the following states:

- **UP:** If probes from all the monitors bound to the service are successful.
- **DOWN**: If monitoring probes to the service are not answered within the configured time limit.
- **OUT OF SERVICE**: If you administratively disable the service, or if you gracefully shut down the service and there are no active transactions to the service
- **GOING OUT OF SERVICE (TROFS)**: If you administratively disable the service with delay, or gracefully shut down the service and there are active transactions to the service. For more in-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

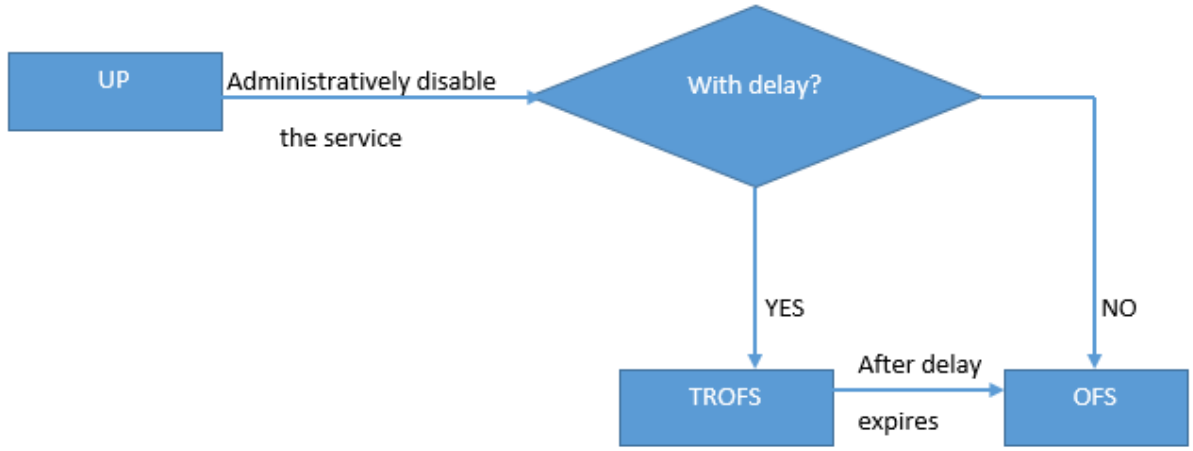


formation, see Graceful Shut down of Services.

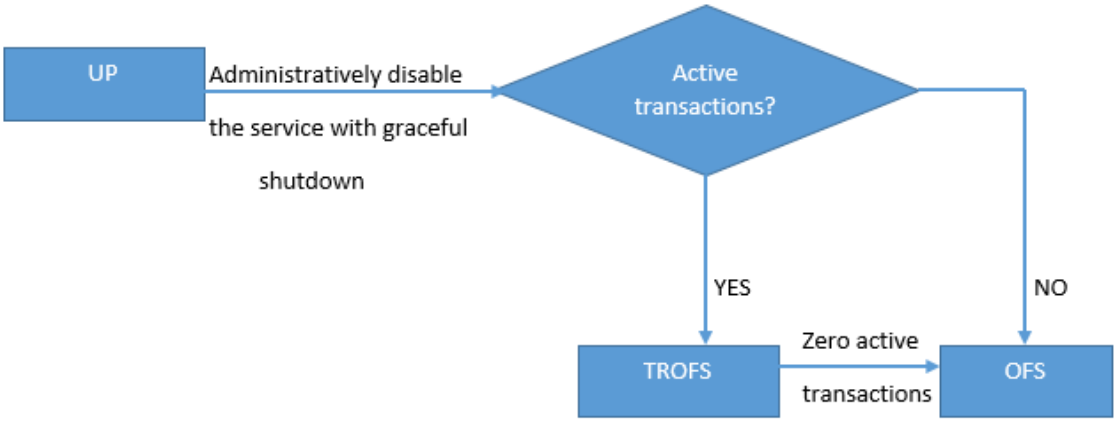


- **DOWN WHEN GOING OUT OF SERVICE (TROFS_DOWN)[]** A monitoring probe fails while the service is in the GOING OUT OF SERVICE state.

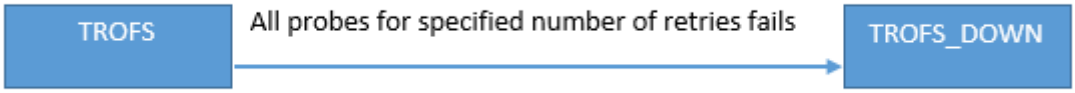
A service in the process of transitioning from UP to OFS is in the GOING OUT OF SERVICE state. A service transitioning from DOWN to OFS is in the DOWN WHEN GOING OUT OF SERVICE state. For example, if a service is DOWN and you disable it with delay, the service transitions to DOWN WHEN GOING OUT OF SERVICE and then to the OUT OF SERVICE state. If a service is UP and you disable it with delay, the service transitions to GOING OUT OF SERVICE. During this time, if a monitoring probe to the server fails, the service transitions to DOWN WHEN GOING OUT OF SERVICE and, after the delay time expires, enters the OFS state.



> **Note**
>
> You can configure spillover to a backup virtual server by setting the "healthThreshold"parameter to a non-zero positive value. Then, if a single service bound to the primary virtual server transitions to the DOWN WHEN GOING OUT OF SERVICE state and the health threshold is not reached, the primary virtual server is marked DOWN and new connections are directed to the backup virtual server.



The following diagrams show the conditions under which a service transitions from one state to another.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Support for load balancing profile

September 14, 2021

A load balancing configuration has many parameters, so setting the same parameters on several virtual servers can become tedious. From release 11.1, a load balancing (LB) profile makes this task

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

easier. You can now set load balancing parameters in a profile and associate this profile with virtual servers, instead of setting these parameters on each virtual server.

The following parameters are presently supported in an LB profile:

- `HTTPonlyflag`—Include the HttpOnly attribute in persistence cookies. The HttpOnly attribute limits the scope of a cookie to HTTP requests and helps mitigate the risk of cross-site scripting attacks.
- UseSecuredPersistenceCookie—Encrypt the persistence cookie values by using the SHA2 hash algorithm.
- `Cookiepassphrase`—Specify the passphrase used to generate a secured persistence cookie value.
- DBS_LB—Enable database specific load balancing for MySQL and MSSQL service types.
- Cl_process_local—Packets destined to a virtual server in a cluster are not steered. Enable the option for single packet request response mode or when the upstream device is performing a proper RSS for connection based distribution.
- lbHashAlgorithm—Specify the hashing algorithm to be used for the following hash-based load balancing methods:
  - URL hash method
  - Domain hash method
  - Destination IP hash method
  - Source IP hash method
  - Source IP Destination IP hash method
  - Source IP Source Port hash method
  - Call ID hash method
  - Token method

  Possible values: DEFAULT, PRAC, JARH
  Default value: DEFAULT
- lbHashFingers—Specify the number of fingers to be used in PRAC and JARH algorithms for hash-based LB methods. Increasing the number of fingers provides better distribution of traffic at the expense of additional memory.

Default value: 256
Minimum value: 1
Maximum value: 1024

> **Note**
>
> You can set DBS_LB and Cl_process_local parameters on a virtual server and in the profile. If

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> you enable these parameters on a virtual server and then set a profile to this virtual server, the parameters appear as disabled in the output of the "show lb vserver" command for that virtual server. Check the profile to see the actual status of these parameters. In addition, if you set and then unset a profile to a virtual server, the parameters are set with default values for that virtual server.

To create an LB profile by using the CLI

At the command prompt, type:

```
add lb profile <lbprofilename> -dbsLb ( ENABLED | DISABLED ) -
    processLocal ( ENABLED | DISABLED ) -httpOnlyCookieFlag ( ENABLED |
    DISABLED ) -cookiePassphrase -useSecuredPersistenceCookie ( ENABLED
    | DISABLED ) -lbHashAlgorithm <lbHashAlgorithm> -lbHashFingers <
    positive_integer>
```

Example:

```
> sh lb profile p1
LB Profile name:  p1
DBS LB : DISABLED   Process Local: DISABLED
Persistence Cookie HttpOnly Flag: ENABLED
Use Encrypted Persistence Cookie: DISABLED
No of vservers bound: 0
Store MQTT clientid and username in transactional logs: NO
Hash LB algorithm used in LB decision: DEFAULT
Number of fingers for Hash LB algorithm: 256
Done
```

To create an LB profile by using the GUI

Navigate to **System** > **Profiles** > **LB Profile**, and add a profile.

To associate an LB profile with an LB virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -lbprofilename <string>
```

Example

```
set lbvserver lbvip1 -lbprofile p1

Done

sh lb vserver lbvip1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
6
7  lbvip1 (203.0.113.1:80) - HTTP       Type: ADDRESS
8  State: UP
9  Last state change was at Wed May 25 12:36:20 2016
10 Time since last state change: 0 days, 00:01:26.140
11 Effective State: UP  ARP:DISABLED
12 Client Idle Timeout: 180 sec
13 Down state flush: ENABLED
14 Disable Primary Vserver On Down : DISABLED
15 Appflow logging: ENABLED
16 Port Rewrite : DISABLED
17 No. of Bound Services :  2 (Total)       2 (Active)
18 Configured Method: LEASTCONNECTION      BackupMethod: ROUNDROBIN
19 Mode: IP
20 Persistence: NONE
21 Vserver IP and Port insertion: OFF
22 Push: DISABLED  Push VServer:
23 Push Multi Clients: NO
24 Push Label Rule: none
25 L2Conn: OFF
26 Skip Persistency: None
27 Listen Policy: NONE
28 IcmpResponse: PASSIVE
29 RHIstate: PASSIVE
30 New Service Startup Request Rate: 0 PER_SECOND, Increment Interval: 0
31 Mac mode Retain Vlan: DISABLED
32 DBS_LB: DISABLED
33 Process Local: DISABLED
34 Traffic Domain: 0
35 LB Profile: p1
36 Done
```

To associate an LB profile with an LB virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Select a virtual server, and click **Edit**.
3. In **Advanced Settings**, click **Profiles**.
4. In the **LB Profile** list, select the profile to associate with this virtual server.

Load balancing algorithms

January 12, 2024

The load balancing algorithm defines the criteria that the Citrix ADC appliance uses to select the service to which to redirect each client request. Different load balancing algorithms use different criteria. For example, the least connection algorithm selects the service with the fewest active connections,

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

while the round robin algorithm maintains a running queue of active services, distributes each connection to the next service in the queue, and then sends that service to the end of the queue.

Some load balancing algorithms are best suited to handling traffic on websites, others to managing traffic to DNS servers, and others to handling complex web applications used in e-commerce or on company LANs or WANs. The following table lists each load balancing algorithm that the Citrix ADC appliance supports, with a brief description of how each operates.

Name	Server selection based on
LEASTCONNECTION	Which service currently has the fewest client connections. This is the default load balancing algorithm.
ROUNDROBIN	Which service is at the top of a list of services. After that service is selected for a connection, it moves to the bottom of the list.
LEASTRESPONSETIME	Which load balanced server currently has the quickest response time.
URLHASH	A hash of the destination URL.
DOMAINHASH	A hash of the destination domain.
DESTINATIONIPHASH	A hash of the destination IP address.
SOURCEIPHASH	A hash of the source IP address.
SRCIPDESTIPHASH	A hash of the source and destination IP addresses.
CALLIDHASH	A hash of the call ID in the SIP header.
SRCIPSRCPORTHASH	A hash of the client's IP address and port.
LEASTBANDWIDTH	Which service currently has the fewest bandwidth constraints.
LEASTPACKETS	Which service currently is receiving the fewest packets.
CUSTOMLOAD	Data from a load monitor.
TOKEN	The configured token.
LRTM	Fewest active connections and the lowest average response time.
Static Proximity	The service that best matches the proximity criteria.
Least Request	Which service currently has the fewest client request.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Name	Server selection based on

Depending on the protocol of the service that it is load balancing, the Citrix ADC appliance sets up each connection between client and server to last for a different time interval. This is called load balancing granularity, of which are three types: request-based, connection-based, and time-based granularity. The following table describes each type of granularity and when each is used.

Granularity	Types of Load Balanced Service	Specifies
Request -based	HTTP or HTTPS	A new service is chosen for each HTTP request, independent of TCP connections. As with all HTTP requests, after the Web server fulfills the request, the connection is closed.
Connection-based	TCP and TCP-based protocols other than HTTP	A service is chosen for every new TCP connection. The connection persists until terminated by either the service or the client.
Time-based	UDP and other IP protocols	A new service is chosen for each UDP packet. Upon selection of a service, a session is created between the service and a client for a specified period. When the time expires, the session is deleted and a new service is chosen for any additional packets, even if those packets come from the same client.

During startup of a virtual server, or whenever the state of a virtual server changes, the virtual server can initially use the round robin method to distribute the client requests among the physical servers. This type of distribution, referred to as *startup round robin,* helps prevent unnecessary load on a single server as the initial requests are served. After using the round robin method at the startup, the virtual server switches to the load balancing method specified on the virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The Startup RR Factor works in the following manner:

- If the Startup RR Factor is set to zero, the appliance switches to the specified load balancing method depending on the request rate.
- If the Startup RR Factor is any number other than zero, the appliance uses the round robin method for the specified number of requests before switching to the specified load balancing method.
- By default, the Startup RR Factor is set to zero.

Note: You cannot set the startup RR Factor for an individual virtual server. The value you specify applies to all the virtual servers on the Citrix ADC appliance.

To set the startup round-robin factor by using the CLI

At the command prompt, type:

```
set lb parameter -startupRRFactor <positive_integer>
```

Example

```
set lb parameter -startupRRFactor 25000
```

To set the startup round-robin factor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, and set the Startup RR Factor.

Least connection method

October 9, 2024

When a virtual server is configured to use the least connection load balancing algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

For TCP, HTTP, HTTPS, and SSL_TCP services, the Citrix ADC appliance includes the following connection types in its list of existing connections:

- **Active connections to a service.** Connections representing requests that a client has sent to the virtual server and that the virtual server has forwarded to a service. For HTTP and HTTPS services, active connections represent only those HTTP or HTTPS requests that have not yet received a response.

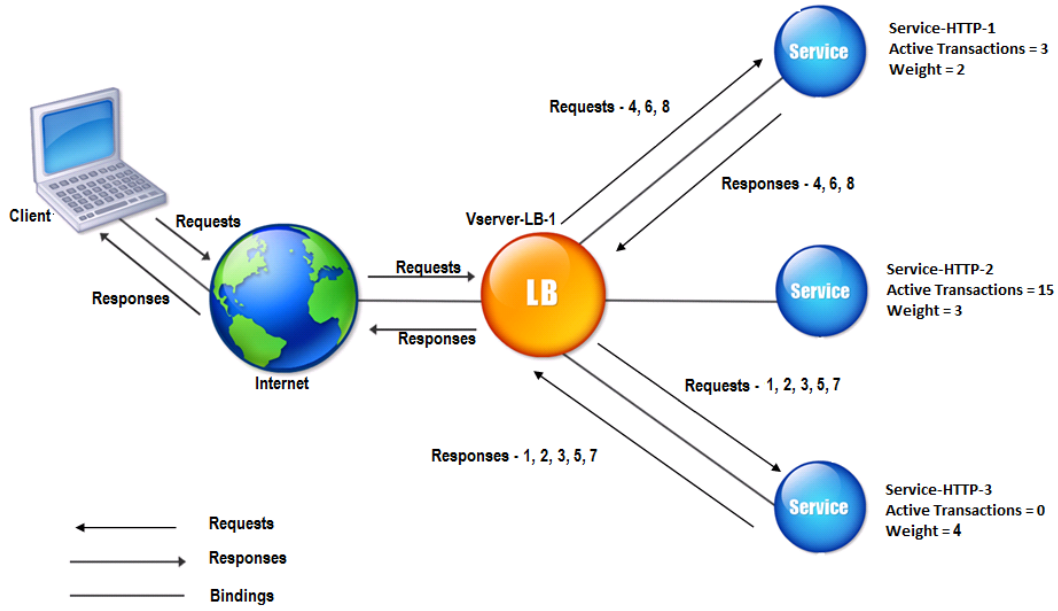
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Waiting connections in the surge queue.** Any connections to the virtual server that are waiting in a surge queue and have not yet been forwarded to a service. Connections can build up in the surge queue at any time, for any of the following reasons:
  - Your services have connection limits, and all services in your load balancing configuration are at that limit.
  - The surge protection feature is configured and has been activated by a surge in requests to the virtual server.
  - The load-balanced server has reached an internal limit and therefore does not open any new connections. (For example, an Apache server's connection limit is reached.)

When a virtual server uses the least connection method, it considers the waiting connections as belonging to the specific service. Therefore, it does not open new connections to those services.

For UDP services, the connections that the least connection algorithm considers include all sessions between the client and a service. These sessions are logical, time-based entities. When the first UDP packet in a session arrives, the Citrix ADC appliance creates a session between the source IP address and port and the destination IP address and port.

For Real-Time Streaming Protocol (RTSP) connections, the Citrix ADC appliance uses the number of active control connections to determine the lowest number of connections to an RTSP service.



The following example shows how a virtual server selects a service for load balancing by using the least connection method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions.
- Service-HTTP-2 is handling 15 active transactions.
- Service-HTTP-3 is not handling any active transactions.

The following diagram illustrates how the Citrix ADC appliance forwards incoming requests when using the least connection method.

Figure 1. Mechanism of the Least Connections Load Balancing Method

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

In this diagram, the virtual server selects the service for each incoming connection by choosing the server with the fewest active transactions.

Connections are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

  Note: The service with no active transaction is selected first.

- Service-HTTP-3 receives the second and third requests because the service has the next least number of active transactions.
- Service-HTTP-1 receives the fourth request because Service-HTTP-1 and Service-HTTP-3 have the same number of active transactions, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. Then, the Citrix ADC appliance starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

  Note: If connections to Service-HTTP-2 close, it might get new connections before each of the other two services has 15 active transactions.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Incoming Connection	Service Selected	Current Number of Active Connections	Remarks
Request-1	Service-HTTP-3; (N = 0)	1	Service-HTTP-3 has the fewest active connections.
Request-2	Service-HTTP-3; (N = 1)	2	Service-HTTP-3 has the fewest active connections.
Request-3	Service-HTTP-3; (N = 2)	3	-
Request-4	Service-HTTP-1; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.
Request-5	Service-HTTP-3; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.
Request-6	Service-HTTP-1;(N = 4)	5	-
Request-7	Service-HTTP-3; (N = 4)	5	-
Request-8	Service-HTTP-1; (N = 5)	6	-

Service-HTTP-2 is selected for load balancing when it completes its active transactions and the current connections to it close, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more connections each.

The Citrix ADC appliance can also use the least connection method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

Nw = (Number of active transactions) * (10000 / weight)

The following example shows how the Citrix ADC appliance selects a service for load balancing by using the least connection method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Connections are forwarded as follows:

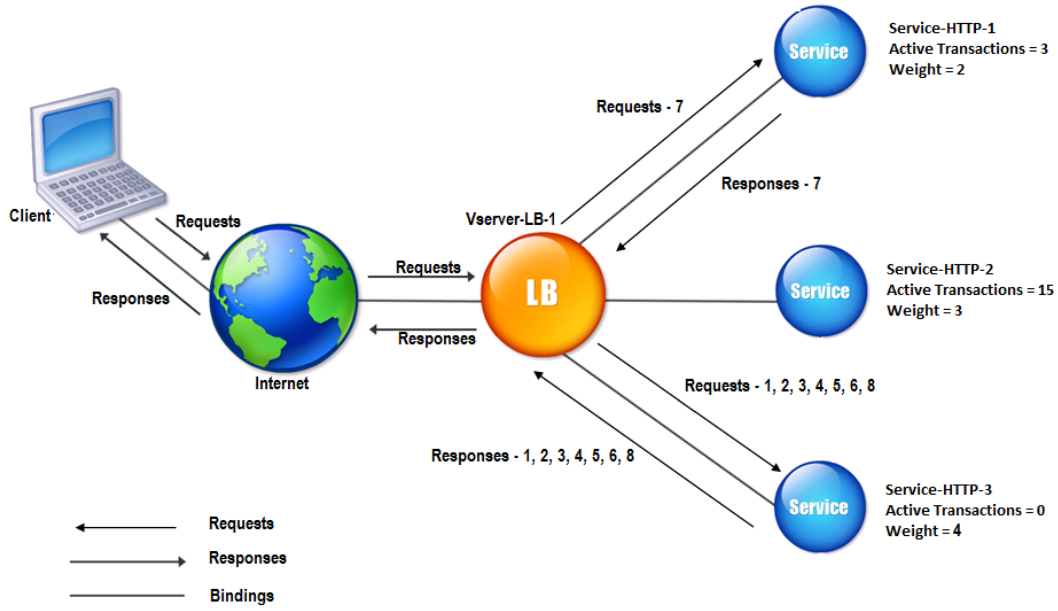
- Service-HTTP-3 receives the first because the service is not handling any active transactions.

  Note: If the services are not handling any active transactions, the Citrix ADC appliance uses the round robin method regardless of the weights assigned to each of the services.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Service-HTTP-3 receives the second, third, fourth, fifth, sixth, and seventh requests because the service has the lowest Nw value.
- Service-HTTP-1 receives the eighth request. Because Service-HTTP-1 and Service-HTTP-3 now have the same Nw value, the appliance performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the ninth request.

The following table explains how connections are distributed on the three-service load balancing setup that is described earlier.



Request Received	Service Selected	Current Nw (Number of active transactions) * (10000 / weight) value	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 2500	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 2500)	Nw = 5000	
Request-3	Service-HTTP-3; (Nw = 5000)	Nw = 7500	
Request-4	Service-HTTP-3; (Nw = 7500)	Nw = 10000	
Request-5	Service-HTTP-3; (Nw = 10000)	Nw = 12500	
Request-6	Service-HTTP-3; (Nw = 12500)	Nw = 15000	
Request-7	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw values
Request-8	Service-HTTP-3; (Nw = 15000)	Nw = 17500	

Service-HTTP-2 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how the Citrix ADC appliance uses the least connection method when weights are assigned to the services.

Figure 2. Mechanism of the Least Connections Load Balancing Method when Weights are Assigned

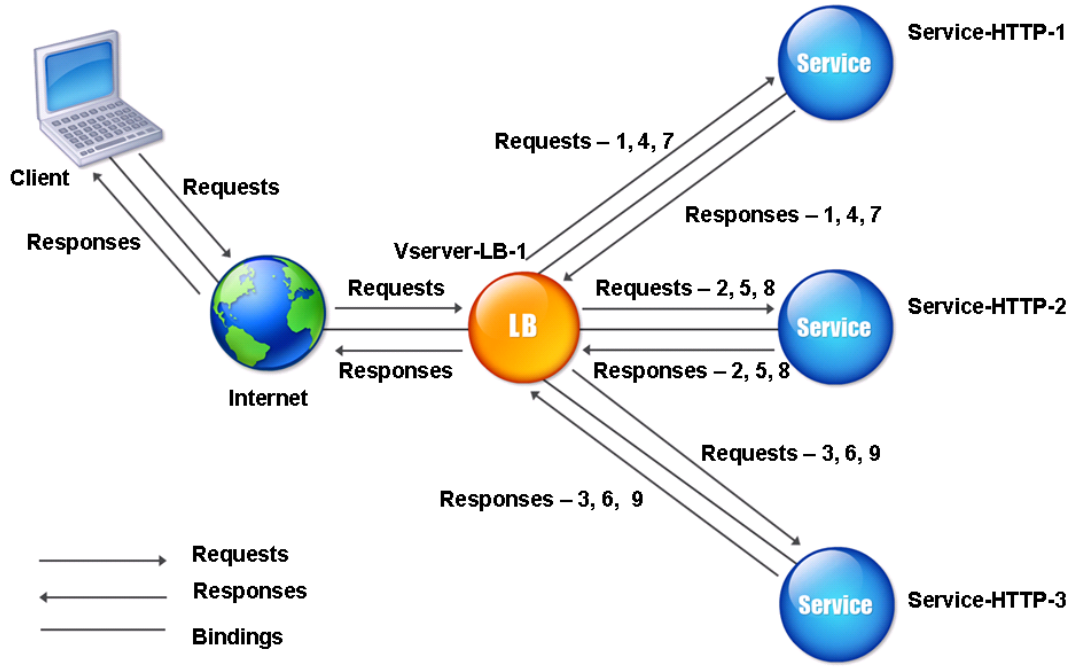
To configure the least connection method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Round robin method



September 14, 2021

When a load balancing virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

The following diagram illustrates how the Citrix ADC appliance uses the round robin method with a load balancing setup that contains three load-balanced servers and their associated services.

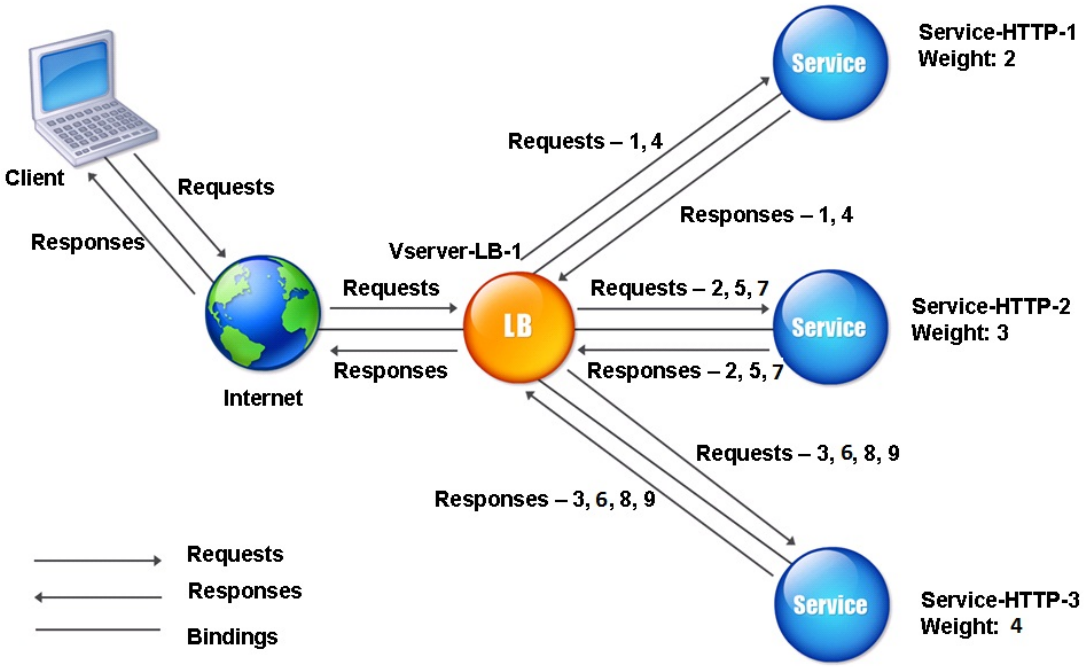
Figure 1. How the Round Robin Load Balancing Method Works

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If you assign a different weight to each service, the Citrix ADC appliance performs the weighted round robin distribution of incoming connections. It does this by skipping the lower-weighted services at appropriate intervals.

For example, assume that you have a load balancing setup with three services. You set Service-HTTP-1 to a weight of 2, Service-HTTP-2 to a weight of 3, and Service-HTTP-3 to a weight of 4. The services are bound to Vserver-LB-1, which is configured to use the round robin method. With this setup, incoming requests are delivered as follows:

- Service-HTTP-1 receives the first request.
- Service-HTTP-2 receives the second request.
- Service-HTTP-3 receives the third request.
- Service-HTTP-1 receives the fourth request.
- Service-HTTP-2 receives the fifth request.
- Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh request.
- Service-HTTP-3 receives both the eighth and the ninth requests.



Note: You can also configure weights on services to prevent multiple services from using the same server and overloading the server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

A new cycle then begins, using the same pattern.

The following diagram illustrates the weighted round robin method.

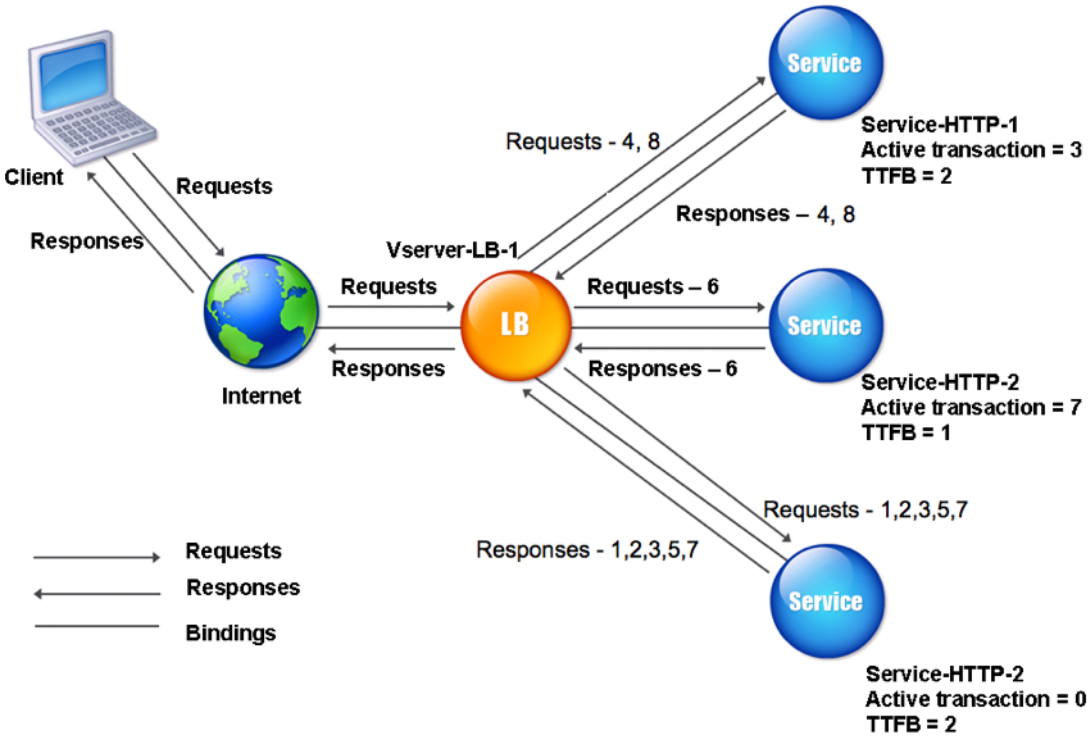
Figure 2. How the Round Robin Load Balancing Method supports Weighted Services

To configure the round robin method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Least response time method

September 14, 2021

When the load balancing virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) load balancing virtual servers only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The Citrix ADC appliance uses response code 200 to calculate TTFB.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following example shows how a virtual server selects a service for load balancing by using the least response time method. Consider the following three services:

- Service-HTTP-1 is handling three active transactions and TTFB is two seconds.
- Service-HTTP-2 is handling seven active transactions and TTFB is one second.
- Service-HTTP-3 is not handling any active transactions and TTFB is two seconds.

The following diagram illustrates how the Citrix ADC appliance uses the least response time method to forward the connections.

Figure 1. How the Least Response Time Load Balancing Method Works

The virtual server selects a service by multiplying the number of active transactions by the TTFB for each service and then selecting the service with the lowest result. For the example shown above, the virtual server forwards requests as follows:

- Service-HTTP-3 receives the first request, because the service is not handling any active transactions.
- Service-HTTP-3 also receives the second and third requests, because the result is the lowest of the three services.
- Service-HTTP-1 receives the fourth request. Since Service-HTTP-1 and Service-HTTP-3 have the same result, the Citrix ADC appliance chooses between them by applying the Round Robin

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

method.

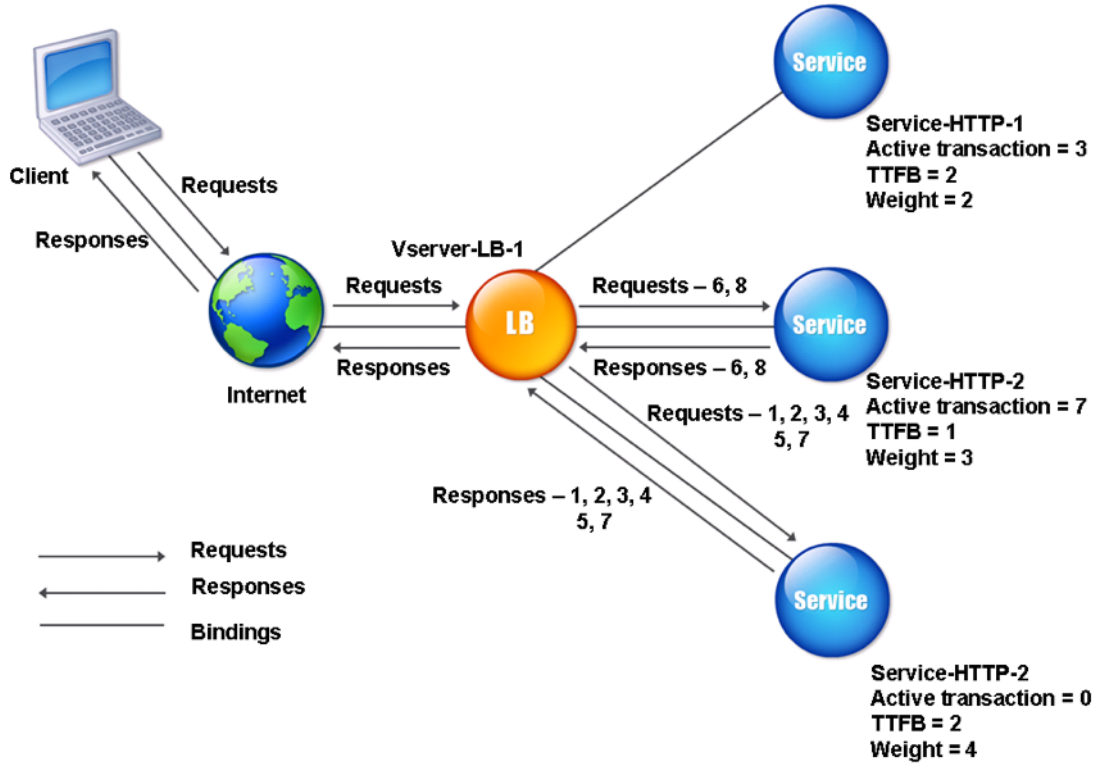
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-2 receives the sixth request, because at this point it has the lowest result.
- Because Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all have the same result at this point, the appliance switches to the round robin method, and continues to distribute connections using that method.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-1	Service-HTTP-3;(N = 0)	N = 2	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-3; (N = 2)	N = 4	Service-HTTP-3 has the lowest N value.
Request-3	Service-HTTP-3; (N = 4)	N = 6	Service-HTTP-3 has the lowest N value.
Request-4	Service-HTTP-1; (N = 6)	N = 8	Service-HTTP-1 and Service-HTTP-3 have the same N values. The appliance uses the round robin method to distribute the requests.
Request-5	Service-HTTP-3; (N = 6)	N = 8	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-6	Service-HTTP-2; (N = 7)	N = 8	Service-HTTP-2 has the lowest N value.
Request-7	Service-HTTP-3; (N = 8)	N = 10	Service-HTTP-1,Service-HTTP-2 and Service-HTTP-3 have the same N values. The Citrix ADC appliance uses the round robin method to distribute the requests.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-8	Service-HTTP-1; (N = 8)	N = 10	Service-HTTP-1 and Service-HTTP-2 have the same N values, the appliance uses the round robin method to distribute the requests.



Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

Selection of services when weights are assigned

The following diagram illustrates how the Citrix ADC appliance uses the least response time method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The virtual server selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight), where N = (number of active transactions * TTFB)

Suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned weight of 3, and Service-HTTP-3 is assigned weight of 4.

The Citrix ADC appliance distributes requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

  If the services are not handling any active transactions, the appliance selects them regardless of the weights assigned to them.
- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and therefore the highest Nw value, so the virtual server does not select it for load balancing.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Request Received	Service Selected	Current Nw Value = (N) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000	Nw = 10000	Service-HTTP-3 has the lowest Nw value.
Request-3	Service-HTTP-3; (Nw = 10000)	Nw = 15000	Service-HTTP-3 has the lowest Nw value.
Request-4	Service-HTTP-3; (Nw = 15000)	Nw = 20000	Service-HTTP-3 has the lowest Nw value.
Request-5	Service-HTTP-3; (Nw = 20000)	Nw = 25000	Service-HTTP-3 has the lowest Nw value.
Request-6	Service-HTTP-2; (Nw = 23333.34)	Nw = 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-7	Service-HTTP-3; (Nw = 25000)	Nw= 30000	Service-HTTP-3 has the lowest Nw value.
Request-8	Service-HTTP-2; (Nw = 26666.67)	Nw = 30000	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

To configure the least response time load balancing method by using the CLI

At the command prompt type;

```
set lb vserver <name> -lbMethod LEASTRESPONSETIME
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod LEASTRESPONSETIME
```

To configure the least response time load balancing method by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **LEASTRESPONSETIME**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For more information about configuring monitors, see Configuring Monitors in a Load Balancing Setup.

LRTM method

September 14, 2021

Note: LRTM stands for Least response time method using monitors (LRTM).

When a load balancing virtual server is configured to use the LRTM method, it uses the existing monitoring infrastructure to get the fastest response time. The load balancing virtual server then selects the service with the smallest number of active transactions and lowest response time. Before you use the LRTM method, you must bind application-specific monitors to each service and enable LRTM mode on these monitors. The Citrix ADC appliance then makes load balancing decisions based on the response times it calculates from monitoring probes.

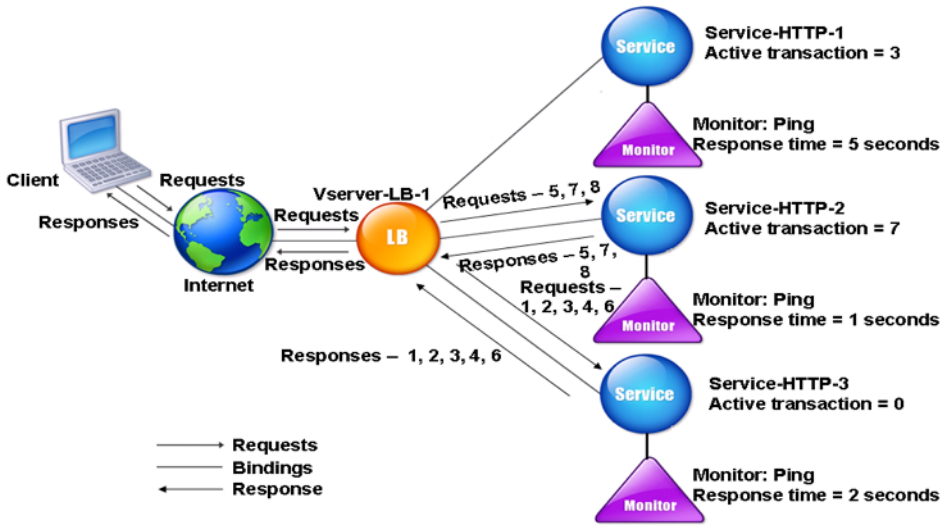
You can use the LRTM method to load balance non-HTTP and non-HTTPS services also. You can also use this method when several monitors are bound to a service. Each monitor determines the response time by using the protocol that it measures for the service that it is bound to. The virtual server then calculates an average response time for that service by averaging the results.

The following table summarizes how response times are calculated for the various monitors.

Monitor	Response time calculation
PING	Time difference between the ICMP ECHO request and the ICMP ECHO response.
TCP	Time difference between the SYN request and the SYN+ACK response.
HTTP	Time difference between the HTTP request (after the TCP connection is established) and the HTTP response.
TCP-ECV	Time difference between the time the data send string is sent and the data receive string is returned. A TCP-ECV monitor without the send and receive strings is considered to have an incorrect configuration.
HTTP-ECV	Time difference between the HTTP request and the HTTP response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Monitor	Response time calculation
UDP-ECV	Time difference between the UDP's send string and the receive string. A UDP-ECV monitor without the receive string is considered to have an incorrect configuration.
DNS	Time difference between a DNS query and the DNS response.
TCPS	Time difference between a SYN request and the SSL handshake completion.
FTP	Time difference between the sending of the user name and the completion of user authentication.
HTTPS (monitors HTTPS requests)	Time difference is the same as for the HTTP monitor.
HTTPS-ECV (monitors HTTPS requests)	Time difference is the same as for the HTTP-ECV monitor
USER	Time difference between the time when a request is sent to the dispatcher and the time when the dispatcher response is received.



The following example shows how the Citrix ADC appliance selects a service for load balancing by using the LRTM method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions and the response time is five seconds.
- Service-HTTP-2 is handling 7 active transactions and the response time is one second.
- Service-HTTP-3 is not handling any active transactions and the response time is two seconds.

The following diagram illustrates the process that the Citrix ADC appliance follows when it forwards requests.

Figure 1. How the LRTM Method Works

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The virtual server selects a service by using the value (N) in the following expression:

N = (Number of active transactions * Response time that is determined by the monitor)

The virtual server delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service is not handling any active transaction.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest N value.
- Service-HTTP-2 receives the fifth request, because this service has the lowest N value.
- Since both Service-HTTP-2 and Service-HTTP-3 currently have the same N value, the Citrix ADC appliance switches to the round robin method. Therefore, Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh and eighth requests, because this service has the lowest N value.

Service-HTTP-1 is not considered for load balancing, because it is more heavily loaded (has the highest N value) when compared to the other two services. However, if Service-HTTP-1 completes its active transactions, the Citrix ADC appliance again considers that service for load balancing.

The following table summarizes how N is calculated for the services.

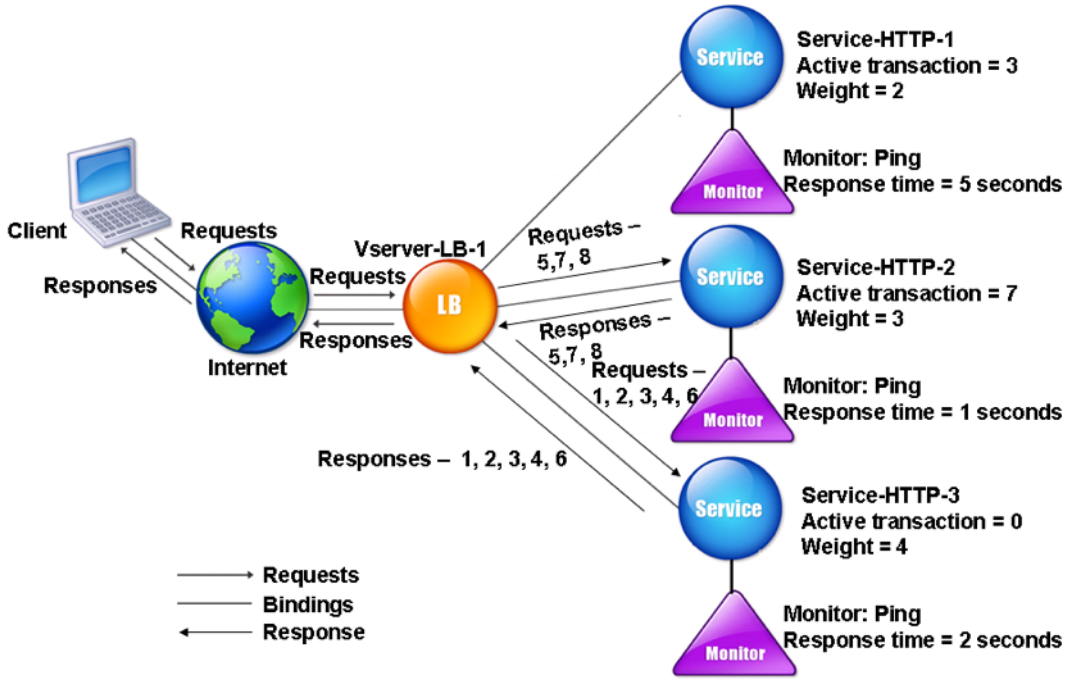
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-1	Service-HTTP-3;(N = 0)	N = 2	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-3; (N = 2)	N = 4	Service-HTTP-3 has the lowest N value.
Request-3	Service-HTTP-3; (N = 4)	N = 6	Service-HTTP-3 has the lowest N value.
Request-4	Service-HTTP-3; (N = 6)	N = 8	Service-HTTP-3 has the lowest N value.
Request-5	Service-HTTP-2; (N = 7)	N = 8	Service-HTTP-2 has the lowest N value.
Request-6	Service-HTTP-3; (N = 8)	N = 10	Service-HTTP-2 and Service-HTTP-3 have the same N values. Citrix ADC appliance switches to the round robin method and selects Service-HTTP-3
Request-7	Service-HTTP-2; (N = 8)	N = 9	Service-HTTP-2 has the lowest N value.
Request-8	Service-HTTP-2; (N = 9)	N = 10	Service-HTTP-2 has the lowest N value.

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

Selection of services when weights are assigned

The Citrix ADC appliance also performs load balancing by using the number of active transactions, response time, and weights if different weights are assigned to services. The Citrix ADC appliance selects the service by using the value (Nw) in the following expression:



Nw = (N) * (10000 / weight)

Where N = (Number of active transactions * Response time that is determined by the monitor)

The following diagram illustrates how the virtual server uses the LRTM method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

In this example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4.

The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth requests, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and the highest Nw value, so the Citrix ADC appliance does not select it for load balancing.

The following table summarizes how Nw is calculated for various monitors.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Request Received	Service Selected	Current Nw Value (N) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000	Nw = 10000	Service-HTTP-3 has the lowest Nw value.
Request-3	Service-HTTP-3; (Nw = 10000)	Nw = 15000	Service-HTTP-3 has the lowest Nw value.
Request-4	Service-HTTP-3; (Nw = 15000)	Nw = 20000	Service-HTTP-3 has the lowest Nw value.
Request-5	Service-HTTP-3; (Nw = 20000)	Nw = 25000	Service-HTTP-3 has the lowest Nw value.
Request-6	Service-HTTP-2; (Nw = 23333.34)	Nw = 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-7	Service-HTTP-3; (Nw = 25000)	Nw= 30000	Service-HTTP-3 has the lowest Nw value.
Request-8	Service-HTTP-2; (Nw = 26666.67)	Nw = 30000	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

To configure the LRTM load balancing method by using the CLI

At the command prompt type;

```
set lb vserver <name> [-lbMethod <lbMethod>]
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod LRTM
```

To configure the LRTM load balancing method by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **LRTM**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable the LRTM option in monitors by using the CLI

At the command prompt type;

```
set lb monitor <monitorName> <type> [-LRTM ( ENABLED | DISABLED )]
```

Example:

```
set lb monitor monitor-HTTP-1 HTTP -LRTM ENABLED
```

To enable the LRTM option in monitors by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**, and open a monitor.
2. In Advanced Parameters, select **LRTM (Least Response Time using Monitoring)**.

For more information about configuring monitors, see Configuring Monitors in a Load Balancing Setup.

Hashing methods

September 14, 2021

Load balancing methods based on hashes of certain connection information or header information constitute most the Citrix ADC appliance's load balancing methods. Hashes are shorter and easier to use than the information that they are based on, while retaining enough information to ensure that no two different pieces of information generate the same hash and are therefore confused with one another.

You can use the hashing load balancing methods in an environment where a cache serves a wide range of content from the Internet or specified origin servers. Caching requests reduces request and response latency, and ensures better resource (CPU) utilization, making caching popular on heavily used websites and application servers. Since these sites also benefit from load balancing, hashing load balancing methods are widely useful.

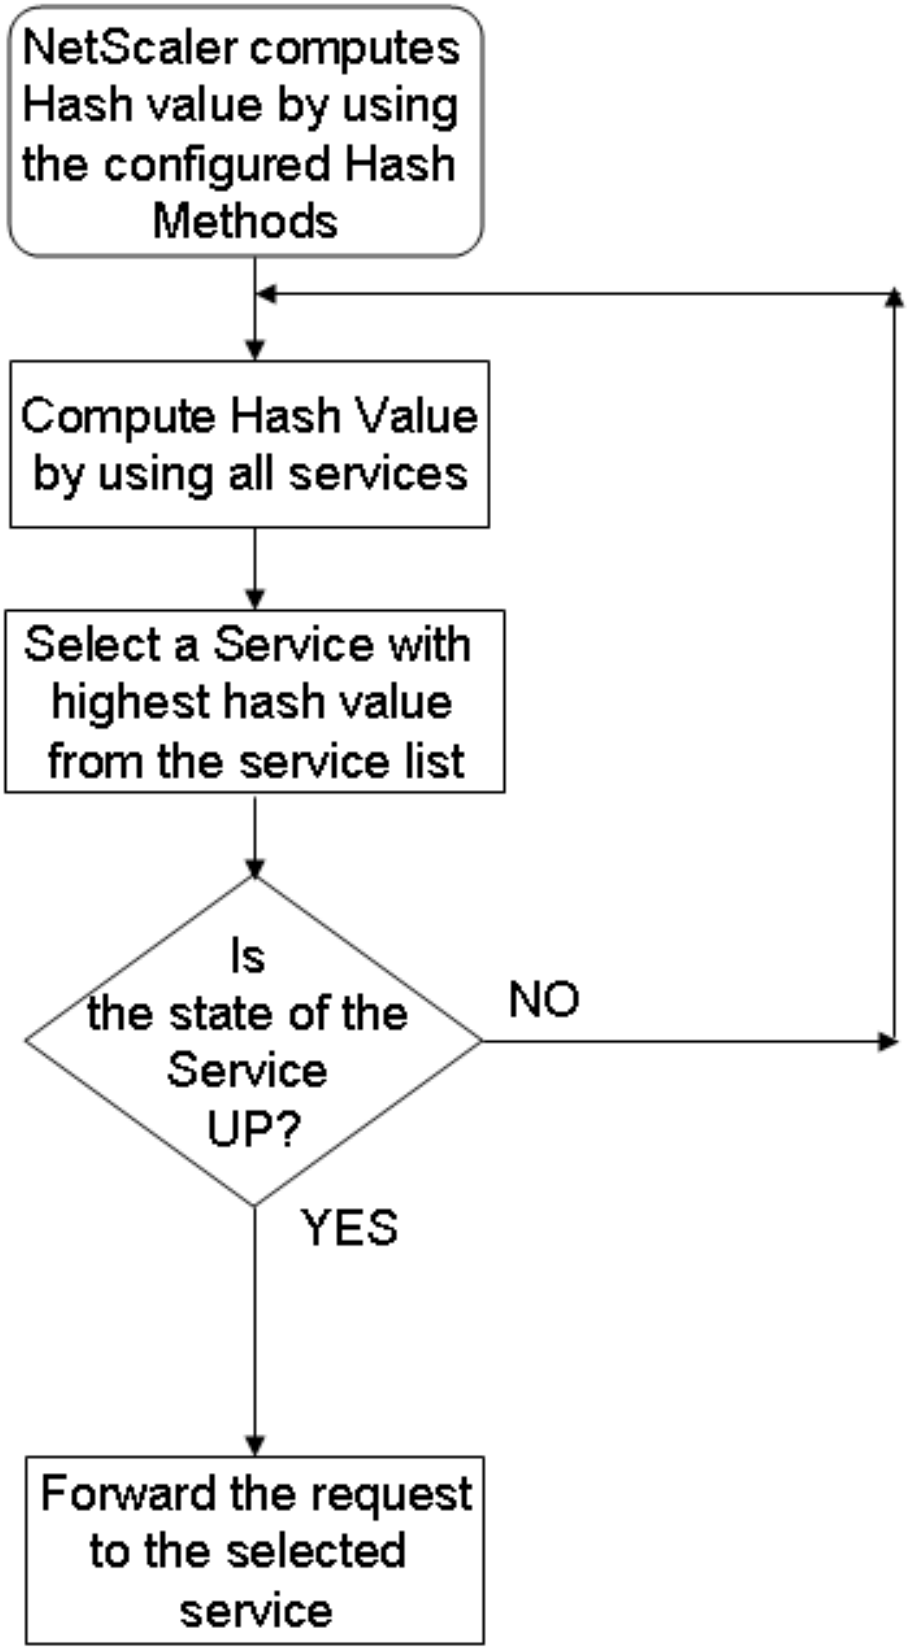
The Citrix ADC appliance provides the following hashing methods:

- URL hash method
- Domain hash method
- Destination IP hash method
- Source IP hash method
- Source IP Destination IP hash method
- Source IP Source Port hash method

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Call ID hash method
- Token method

Most of the hashing algorithms calculate two hash values:



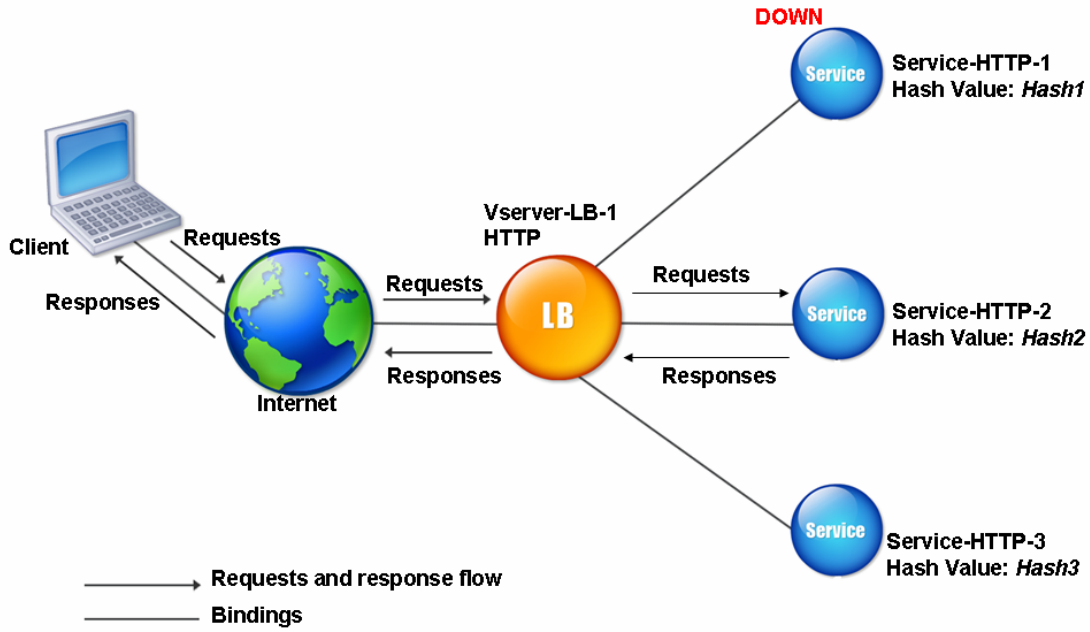
- A hash of the service's IP address and port.
- A hash of the incoming URL, the domain name, the source IP address, the destination IP address, or the source and destination IP addresses, depending on the configured hash method.

The Citrix ADC appliance then generates a new hash value by using both of those hash values. Finally, it forwards the request to the service with the highest hash value. As the appliance computes a hash value for each request and selects the service that processes the request, it populates a cache. Subsequent requests with the same hash value are sent to the same service. The following flow chart illustrates this process.

> Note
>
> Starting from Citrix ADC release 13.0 build 79.x, Prime Re-Shuffled Assisted CARP (PRAC) and Jump table Assisted Ring Hash (JARH) consistent hashing algorithms are supported. The consistent hashing algorithms ensure minimal disruption when services are added to or deleted from your load balancing setup, or during a service flap event in load balancing setup. For more details, see Consistent hashing algorithms.

Figure 1. How the Hashing Methods Distribute Requests

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Hashing methods can be applied to IPv4 and IPv6 addresses.

Consider a scenario where three services (Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3) are bound to a virtual server, any hash method is configured, and the hash value is Hash1. When the configured services are UP, the request is sent to Service-HTTP-1. If Service-HTTP-1 is down, the Citrix ADC appliance calculates the hash value for the last log of the number of services. The appliance then selects the service with the highest hash value, such as Service-HTTP-2. The following diagram illustrates this process.

Figure 2. Entity Model for Hashing Methods

> Note
>
> If the Citrix ADC appliance fails to select a service by using a hashing method, it defaults to the least connection method to select a service for the incoming request. Adjust server pools by removing services during periods of low traffic to enable the caches to repopulate without affecting performance on your load balancing setup.

Consistent hashing algorithms

The consistent hashing algorithms are used to achieve stateless persistency. The hash-based LB methods use one of the following three consistent hashing algorithms:

- **Cache Array Routing Protocol (CARP)**

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The CARP algorithm is used in load-balancing HTTP requests across multiple proxy cache servers. This algorithm is enabled by default.

- **Prime Re-Shuffled Assisted CARP (PRAC)**

  The Citrix ADC appliance uses the proprietary PRAC algorithm to provide uniform traffic distribution.

- **Jump table Assisted Ring Hash (JARH)**

  The Citrix ADC appliance uses the proprietary JARH algorithm to provide consistency and uniform distribution of the traffic. This algorithm uses hash fingers. Higher number of fingers provide better distribution of traffic. However, increasing the number of fingers increases the memory usage as well.

To choose the consistent hashing algorithm by using CLI

```
set lb parameter [-lbHashAlgorithm [DEFAULT|JARH|PRAC] [-lbHashFingers
    <positive_integer>]
```

Example:

```
set lb parameter -lbHashAlgorithm JARH -lbHashFingers 10
```

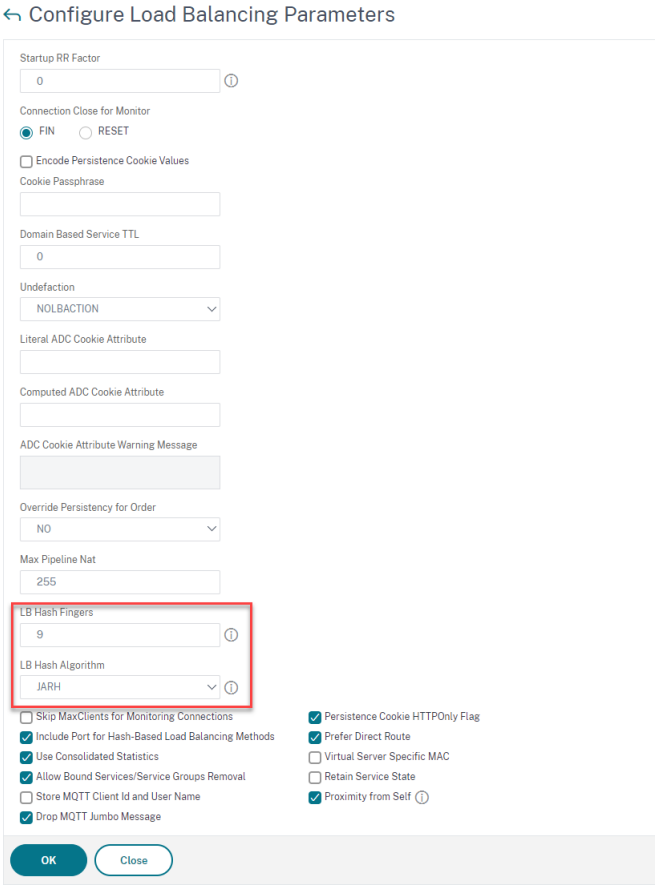
ARGUMENTS:

- **lbHashAlgorithm**-Specify the hashing algorithm to be used for the following hash-based load balancing methods:

  - URL hash method
  - Domain hash method
  - Destination IP hash method
  - Source IP hash method
  - Source IP Destination IP hash method
  - Source IP Source Port hash method
  - Call ID hash method
  - Token method

  Possible values: DEFAULT, PRAC, JARH
  Default value: DEFAULT

- **lbHashFingers**-Specify the number of fingers to be used in PRAC and JARH algorithms for hash-based LB methods. Increasing the number of fingers provides better distribution of traffic at the expense of extra memory.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Default value: 256
Minimum value: 1
Maximum value: 1024

To choose the consistent hashing algorithm by using GUI

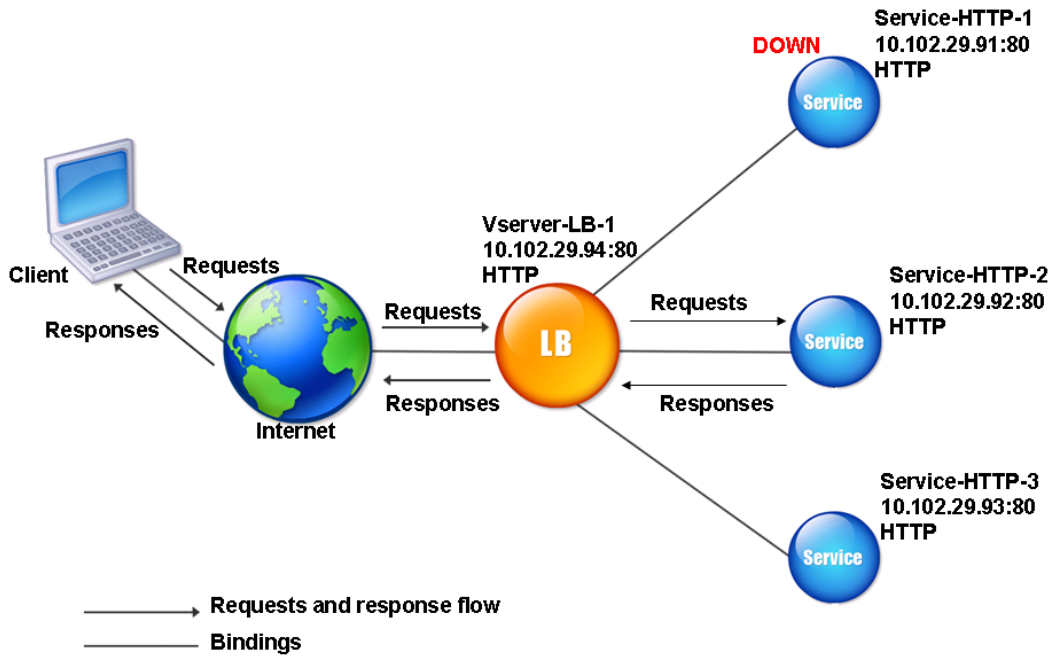
1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing parameters**.
2. In the **Configure Load Balancing Parameters** pane, enter appropriate values for the following fields based on your requirement:

   - LB Hash Fingers
   - In the **LB Hash Algorithm** field, choose the consistent hashing algorithm from the drop-down menu.

The URL Hash Method

When you configure the Citrix ADC appliance to use the URL hash method for load balancing the services, for selecting a service, the appliance generates a hash value of the HTTP URL present in the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



incoming request. If the service selected by the hash value is DOWN, the algorithm has a method to select another service from the list of active services. The appliance caches the hashed value of the URL, and when it receives subsequent requests that use the same URL, it forwards them to the same service. If the appliance cannot parse an incoming request, it uses the round robin method for load balancing instead of the URL hash method.

For generating the hash value, the appliance uses a specific algorithm and considers a part of the URL. By default, the appliance considers the first 80 bytes of the URL. If the URL is of less than 80 bytes, the complete URL is used. You can specify a different length. The hash length can be from 1 byte to 4096 bytes. Generally, if long URLs are used where only a few characters are different, it is a good idea to make the hash length as high as possible to try to ensure a more even load distribution.

Consider a scenario where three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3, are bound to a virtual server, and the load balancing method configured on the virtual server is the URL hash method. The virtual server receives a request and the hash value of the URL is U1. Appliance selects Service-HTTP-1. If Service-HTTP-1 is DOWN, the appliance selects Service-HTTP-2.

The following diagram illustrates this process.

Figure 3. How URL Hashing Operates

If both Service-HTTP-1 and Service-HTTP-2 are DOWN, the appliance sends requests with hash value

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

U1 to Service-HTTP-3.

If Service-HTTP-1 and Service-HTTP-2 are down, requests that generate the hash URL1 are sent to Service-HTTP-3. If these services are UP, the requests that generate the hash URL1 are distributed in the following manner:

- If the Service-HTTP-2 is up, the request is sent to Service-HTTP-2.
- If the Service-HTTP-1 is up, the request is sent to Service-HTTP-1.
- If Service-HTTP-1 and Service-HTTP-2 are up at the same time, the request is sent to Service-HTTP-1.

To configure the URL hash method, see Configuring a Load Balancing Method that Does Not Include a Policy. Select the load balancing method as URL Hash, and set the hash length to the number of bytes to be used for generating the hash value.

The Domain Hash Method

A load balancing virtual server configured to use the domain hash method uses the hashed value of the domain name in the HTTP request to select a service. The domain name is taken from either the incoming URL or the Host header of the HTTP request. If the domain name appears in both the URL and the Host header, the appliance gives preference to the URL.

If you configure domain name hashing, and an incoming HTTP request does not contain a domain name, the Citrix ADC appliance defaults to the round robin method for that request.

The hash-value calculation uses the name length or hash length value, whichever is smaller. By default, the Citrix ADC appliance calculates the hash value from the first 80 bytes of the domain name. To specify a different number of bytes in the domain name when calculating the hash value, you can set the hashLength parameter (Hash Length in the configuration utility) to a value of from 1 to 4096 (bytes).

To configure the domain hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Destination IP Hash Method

A load balancing virtual server configured to use the destination IP hash method uses the hashed value of the destination IP address to select a server. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same server. This method supports IPv4 and IPv6-based destination servers.

This load balancing method is appropriate for use with the cache redirection feature.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure the destination IP hash method for an IPv4 destination server, you set the netMask parameter. To configure this method for an IPv6 destination server, you use the v6NetMaskLen parameter. In the configuration utility, text boxes for setting these parameters appear when you select the **Destination IP Hash method**.

To configure the destination IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Hash Method

A load balancing virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Destination IP Hash Method

A load balancing virtual server configured to use the source IP destination IP hash method uses the hashed value of the source and destination IP addresses (either IPv4 or IPv6) to select a service. Hashing is symmetric. The hash value is the same regardless of the order of the source and destination IPs. This ensures that all packets flowing from a particular client to the same destination are directed to the same server.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP destination IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Source IP Source Port Hash Method

A load balancing virtual server configured to use the source IP source port hash method uses the hash value of the source IP (either IPv4 or IPv6) and the source port to select a service. This ensures that all packets on a particular connection are directed to the same service.

This method is used in connection mirroring and firewall load balancing. For more information about connection mirroring, see Connection Failover.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP source port hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Call ID Hash Method

A load balancing virtual server configured to use the call ID hash method uses the hash value of the call ID in the SIP header to select a service. Packets for a particular SIP session are therefore always directed to the same proxy server.

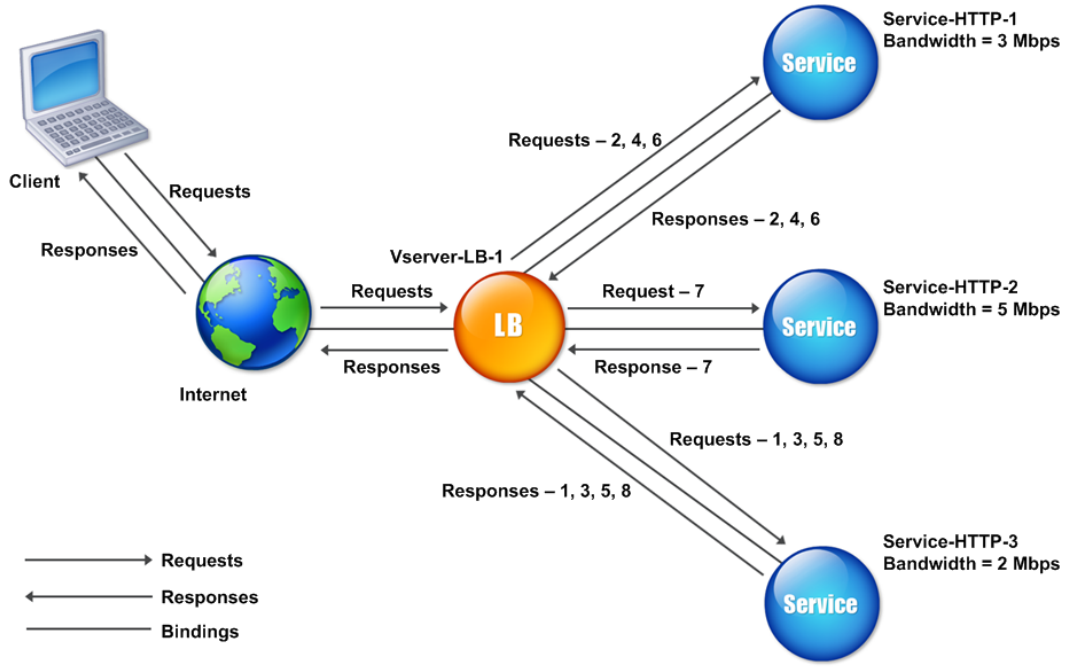
This method is applicable to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure the call ID hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Least bandwidth method

September 14, 2021

A load balancing virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for load balancing by using the least bandwidth method.



Consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has 3 Mbps bandwidth.
- Service-HTTP-2 has 5 Mbps bandwidth.
- Service-HTTP-3 has 2 Mbps bandwidth.

The following diagram illustrates how the virtual server uses the least bandwidth method to forward requests to the three services.

Figure 1. How the Least Bandwidth Load Balancing Method Works

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The virtual server selects the service by using the bandwidth value (N), which is the sum of the number of bytes transmitted and received over the previous 14 seconds. If each request requires 1 Mbps bandwidth, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Because Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method for these servers, alternating between them. Service-HTTP-1 receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 now all have the same N value, the virtual server includes Service-HTTP-2 in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

Request Received	Service Selected	Current N Value	Remarks
Request-1	Service-HTTP-3; (N = 2)	N = 3	Service-HTTP-3 has the lowest N value.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Request Received	Service Selected	Current N Value	Remarks
Request-2	Service-HTTP-1; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-3	Service-HTTP-3;(N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-4	Service-HTTP-1; (N = 4)	N = 5	-
Request-5	Service-HTTP-3; (N = 4)	N = 5	-
Request-6	Service-HTTP-1; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-3; (N = 5)	N = 6	-

Note: If you enable the RTSP NAT option on the virtual server, the Citrix ADC appliance uses the number of data and control bytes exchanged to determine the bandwidth usage for RTSP services. For more information about the RTSP NAT option, see Managing RTSP Connections.

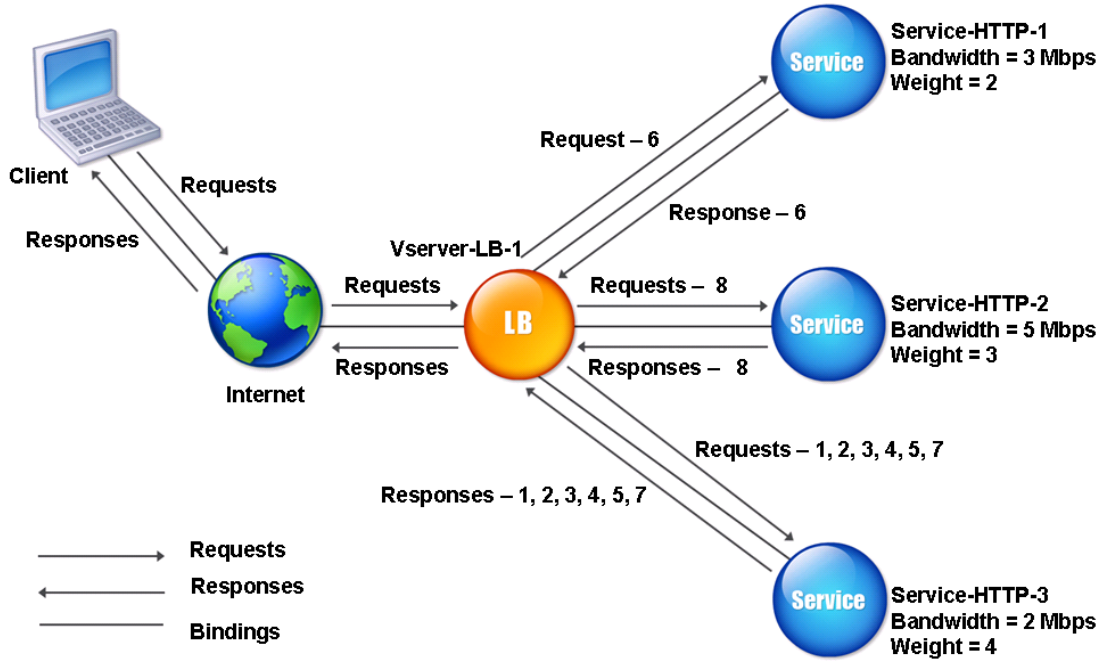
The Citrix ADC appliance also performs load balancing by using the bandwidth and weights if different weights are assigned to the services. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 5000)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000)	Nw = 7500	-
Request-3	Service-HTTP-3; (Nw = 7500)	Nw = 10000	-
Request-4	Service-HTTP-3; (Nw = 10000)	Nw = 12500	-
Request-5	Service-HTTP-3; (Nw = 12500)	Nw = 15000	-
Request-6	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-7	Service-HTTP-3; (Nw = 15000)	Nw = 17500	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-8	Service-HTTP-2; (Nw = 16666.67)	Nw = 20000	Service-HTTP-2 has the lowest Nw value.

The following diagram illustrates how the virtual server uses the least bandwidth method when weights are assigned to the services.

Figure 2. How the Least Bandwidth Load Balancing Method Works When Weights Are Assigned

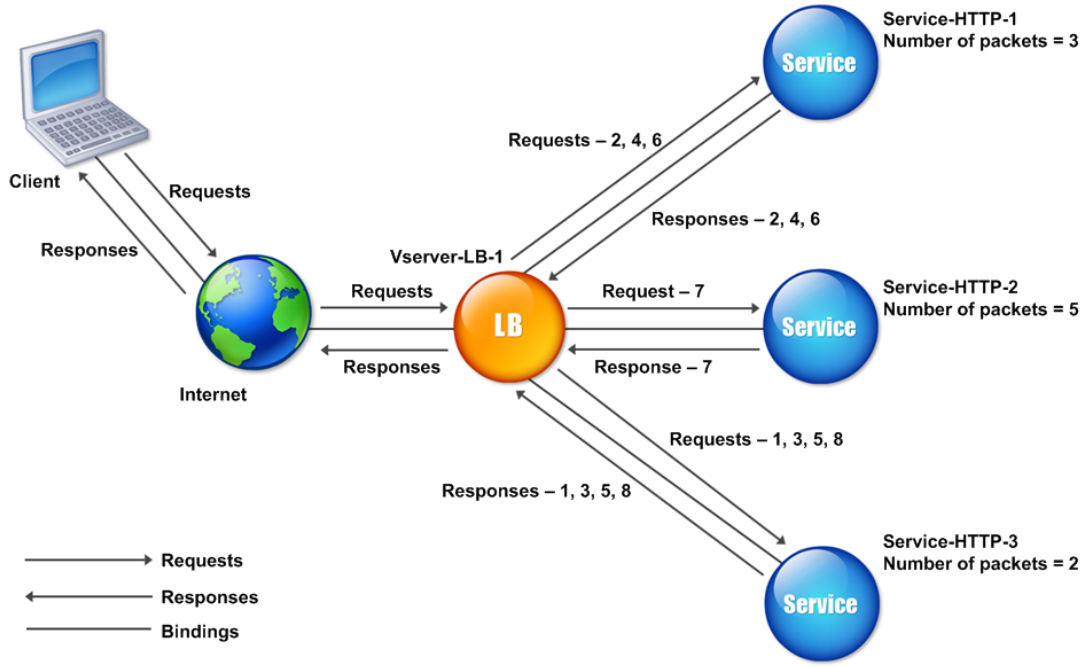
To configure the least bandwidth method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Least packets method

September 14, 2021

A load balancing virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.



For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has handled three packets in the last 14 seconds.
- Service-HTTP-2 has handled five packets in the last 14 seconds.
- Service-HTTP-3 has handled two packets in the last 14 seconds.

The following diagram illustrates how the Citrix ADC appliance uses the least packets method to choose a service for each request that it receives.

Figure 1. How the Least Packets Load Balancing Method Works

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The Citrix ADC appliance selects a service by using the number of packets (N) transmitted and received by each service in the last 14 seconds. Using this method, it delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method. Service-HTTP-1 therefore receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have the same N value, the virtual server switches to the round robin method for Service-HTTP-2 as well, including it in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

Request Received	Service Selected	Current N Value	Remarks
Request-1	Service-HTTP-3; (N = 2)	N = 3	Service-HTTP-3 has the lowest N value.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Request Received	Service Selected	Current N Value	Remarks
Request-2	Service-HTTP-1; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-3	Service-HTTP-3; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-4	Service-HTTP-1; (N = 4)	N = 5	-
Request-5	Service-HTTP-3; (N = 4)	N = 5	-
Request-6	Service-HTTP-1; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-3; (N = 5)	N = 6	-

Note: If you enable the RTSP NAT option on the virtual server, the appliance uses the number of data and control packets to calculate the number of packets for RTSP services. For more information about the RTSP NAT option, see Managing RTSP Connections.

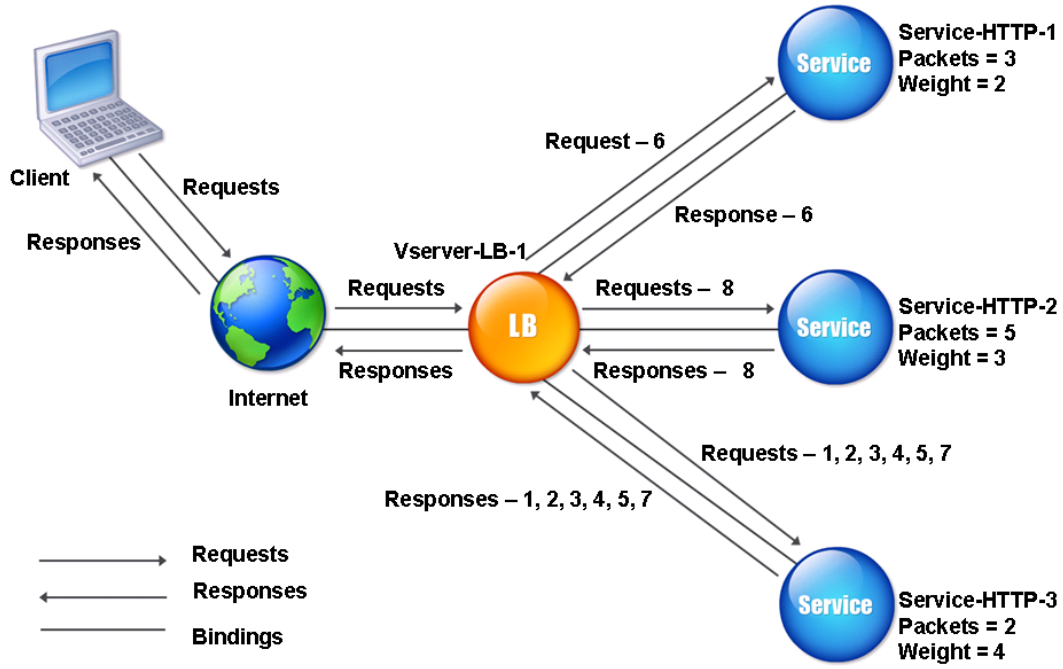
The Citrix ADC appliance also performs load balancing by using the number of packets and weights when a different weight is assigned to each service. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 5000)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000)	Nw = 7500	-
Request-3	Service-HTTP-3;(Nw = 7500)	Nw = 10000	-
Request-4	Service-HTTP-3; (Nw = 10000)	Nw = 12500	-
Request-5	Service-HTTP-3; (Nw = 12500)	Nw = 15000	-
Request-6	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-7	Service-HTTP-3; (Nw = 15000)	Nw = 17500	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-8	Service-HTTP-2; (Nw = 16666.67)	Nw = 20000	Service-HTTP-2 has the lowest Nw value.

The following diagram illustrates how the virtual server uses the least packets method when weights are assigned.

Figure 2. How the Least Packets Method Works When Weights Are Assigned

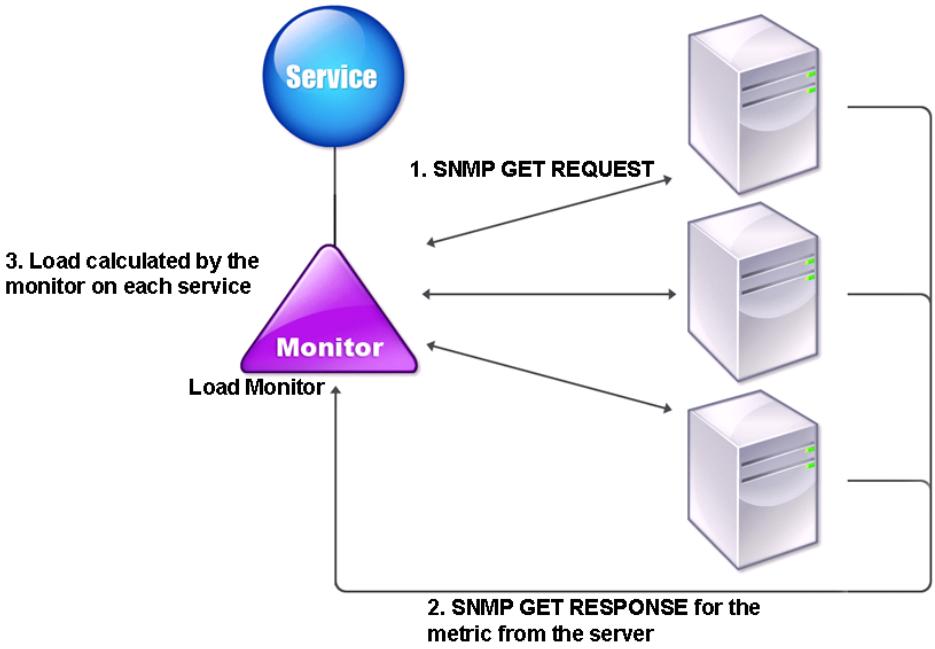
To configure the least packets method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Custom load method



September 14, 2021

Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the Citrix ADC appliance usually selects a service that is not handling any active transactions. If all the services in the load balancing setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the load balancing decision when those services are not UP.

For more information about load monitors, see Understanding Load Monitors. The following diagram illustrates how a load monitor operates.

Figure 1. How Load Monitors Operate

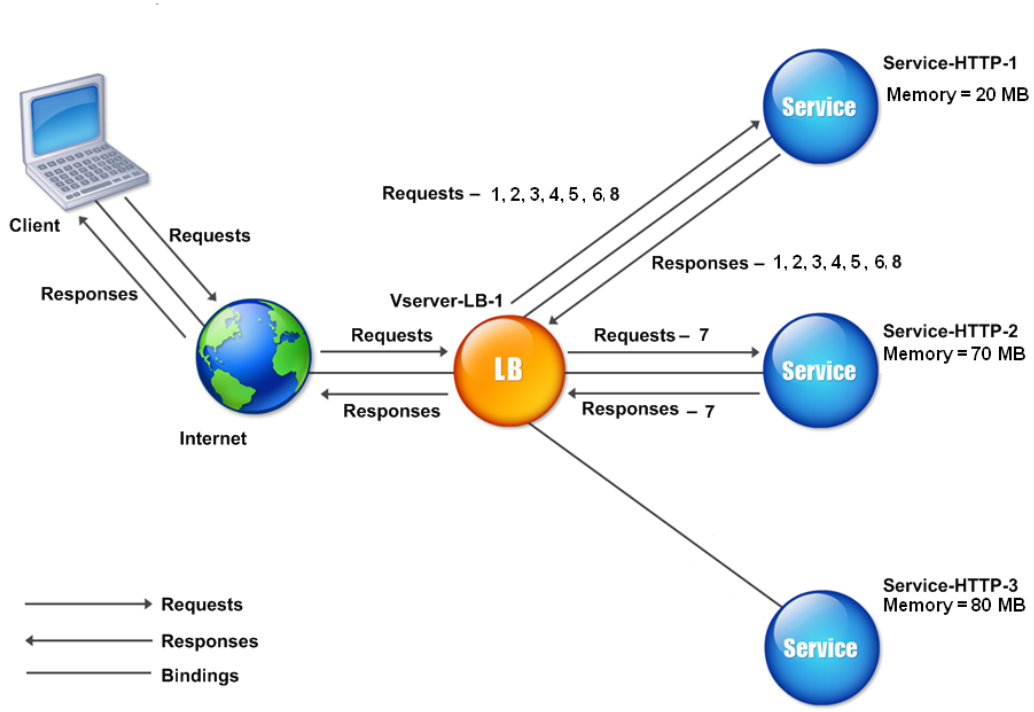
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The load monitor uses SNMP probes to calculate the load on each service by sending an SNMP GET request to the service. This request contains one or more object IDs (OIDs). The service responds with an SNMP GET response, with metrics corresponding to the SNMP OIDs. The load monitor uses the response metrics to calculate the load on the service.

The load monitor calculates the load on a service by using the following parameters:

- Metrics values retrieved through SNMP probes that exist as tables in the Citrix ADC appliance.
- Threshold value set for each metric.
- Weight assigned to each metric.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.



- Service-HTTP-1 is using 20 MB of memory.
- Service-HTTP-2 is using 70 MB of memory.
- Service-HTTP-3 is using 80 MB of memory.

The load balanced servers can export metrics such as CPU and memory usage to the services, which can in turn provide them to the load monitor. The load monitor sends an SNMP GET request containing the OIDs 1.3.6.1.4.1.5951.4.1.1.41.1.5, 1.3.6.1.4.1.5951.4.1.1.41.1.4, and 1.3.6.1.4.1.5951.4.1.1.41.1.3 to the services. SNMP OIDs of type STRING are not supported, because you cannot calculate the load by

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

using a STRING OID. Loads can be calculated by using other data types, such as INT and gauge32. The three services respond to the request. The Citrix ADC appliance compares the exported metrics, and then selects Service-HTTP-1 because it has more available memory. The following diagram illustrates this process.

Figure 2. How the Custom Load Method Works

If each request uses 10 MB memory, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, and fifth requests, because this service has the lowest N value.
- Service-HTTP-1 and Service-HTTP-2 now have the same load, so the virtual server reverts to the round robin method for these servers. Therefore, Service-HTTP-2 receives the sixth request, and Service-HTTP-1 receives the seventh request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have the same load, the virtual server reverts to the round robin method for Service-HTTP-3 as well. Therefore, Service-HTTP-3 receives the eighth request.

The following table summarizes how N is calculated.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Request received	Service selected	Current N Value (Number of Active Transactions)	Remarks
Request-1	Service-HTTP-1; (N = 20)	N = 30	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-1; (N = 30)	N = 40	-
Request-3	Service-HTTP-1; (N = 40)	N = 50	-
Request-4	Service-HTTP-1; (N = 50)	N = 60	-
Request-5	Service-HTTP-1; (N = 60)	N = 70	-
Request-6	Service-HTTP-1; (N = 70)	N = 80	Service-HTTP-2 and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 70)	N = 80	Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-1; (N = 80)	N = 90	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.

If different weights are assigned to the services, the custom load algorithm considers both the load on each service and the weight assigned to each service. It selects a service by using the value (Nw) in the following expression:

Nw = (N) * (10000 / weight)

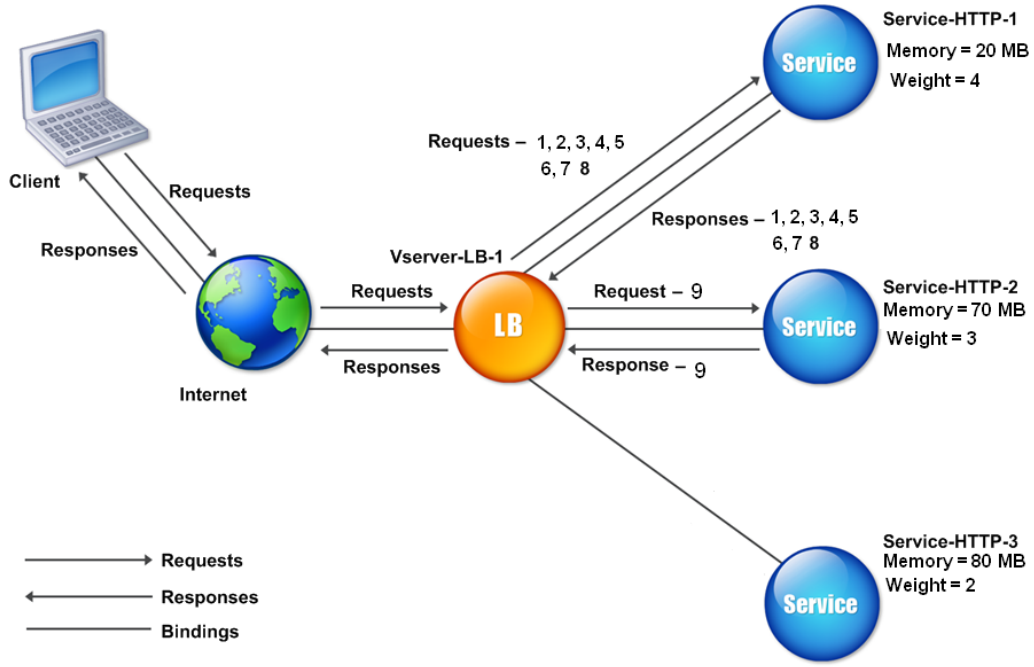
As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 4, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 2. If each request uses 10 MB memory, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, fifth, sixth, seventh, and eighth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the ninth request, because this service has the lowest Nw value.

Service-HTTP-3 has the highest Nw value, and is therefore not considered for load balancing.

The following table summarizes how Nw is calculated.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



Request received	Service selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-1; (Nw = 50000)	Nw = 75000	Service-HTTP-1 has the lowest Nw value.
Request-2	Service-HTTP-1; (Nw = 5000)	Nw = 100000	-
Request-3	Service-HTTP-1; (Nw = 15000)	Nw = 125000	-
Request-4	Service-HTTP-1; (Nw = 20000)	Nw = 150000	-
Request-5	Service-HTTP-1; (Nw = 23333.34)	Nw = 175000	-
Request-6	Service-HTTP-1; (Nw = 25000)	Nw = 200000	-
Request-7	Service-HTTP-1; (Nw = 23333.34)	Nw = 225000	-
Request-8	Service-HTTP-1; (Nw = 25000)	Nw = 250000	
Request-9	Service-HTTP-2; (Nw = 233333.34)	Nw = 266666.67	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-2 and Service-HTTP-3) is equal to 400,000.

The following diagram illustrates how the Citrix ADC appliance uses the custom load method when weights are assigned.

Figure 3. How the Custom Load Method Works When Weights Are Assigned

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure the custom load method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Static proximity method

September 14, 2021

When a virtual server is configured to use the static proximity method, it selects the service that best matches the proximity criteria.

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the load balancing method.

For more details, see the following topics.

- Adding a Location File to Create a Static Proximity Database
- Adding Custom Entries to a Static Proximity Database

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Setting the Location Qualifiers
- Specifying the Static Proximity method

Specifying the Proximity Method

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
set lb vserver <name> -lbMethod STATICPROXIMITY

show lb vserver <name>
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod STATICPROXIMITY

show lb vserver
```

To specify static proximity by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** and select the virtual server.
2. Click **Edit** and expand the **Method** section.
3. In the **Load Balancing Method** list, select **STATICPROXIMITY**.

Token method

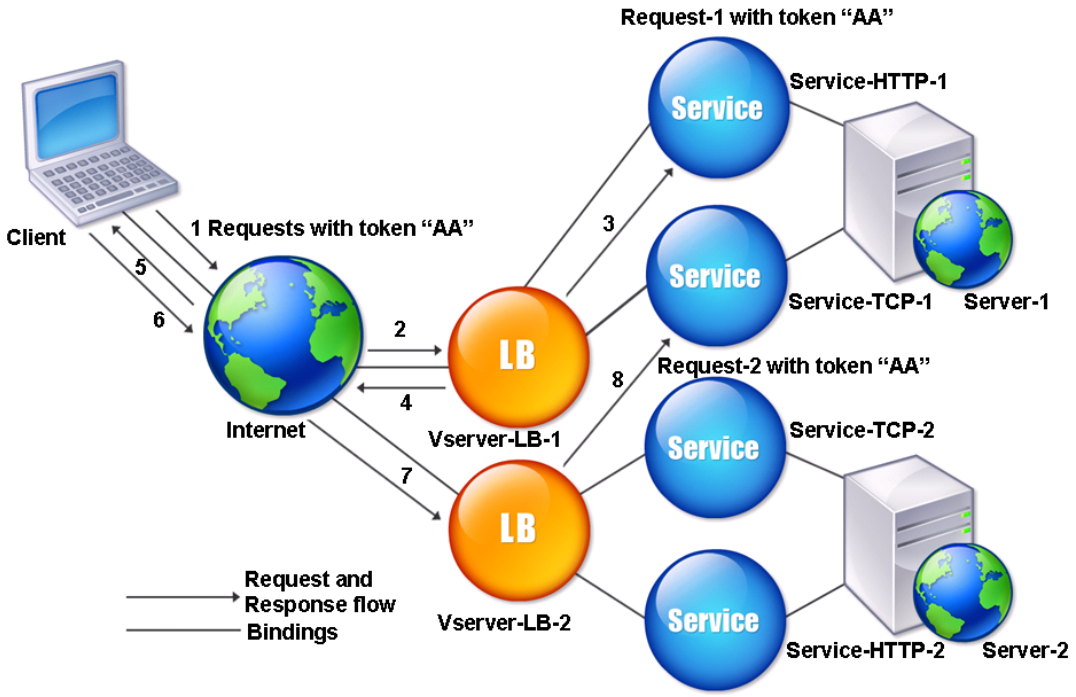
September 14, 2021

A load balancing virtual server configured to use the token method bases its selection of a service on the value of a data segment extracted from the client request. The data segment is called the token. You configure the location and size of the token. For subsequent requests with the same token, the virtual server chooses the same service that handled the initial request.

This method is content aware. It operates differently for TCP, HTTP, and HTTPS connections. For HTTP or HTTPS services, the token is found in the HTTP headers, the URL, or the BODY. To locate the token,

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

you specify or create a classic or advanced expression. For more information on classic or advanced expressions, see Policy Configuration and Reference.



For HTTP services, the virtual server searches for the configured token in the first 24 kilobytes (KB) of the TCP payload. For non-HTTP (TCP, SSL, and SSL_TCP) services, the virtual server searches for the configured token in the first 16 packets if the total size of the 16 packets is less than 24 KB. But if the total size of the 16 packets is greater than 24 KB, the appliance searches for the token in the first 24 KB of payload. You can use this load balancing method across virtual servers of different types to make sure that requests presenting the same token are directed to appropriate services, regardless of the protocol used.

For example, consider a load balancing setup consisting of servers that contain Web content. You want to configure the Citrix ADC appliance to search for a specific string (the token) inside the URL query portion of the request. Server-1 has two services, Service-HTTP-1 and Service-TCP-1, and Server-2 has two services, Service-HTTP-2 and Service-TCP-2. The TCP services are bound to Vserver-LB-2, and the HTTP services are bound to Vserver-LB-1.

If Vserver-LB-1 receives a request with the token AA, it selects the service Service-HTTP-1 (bound to server-1) to process the request. If Vserver-LB-2 receives a different request with the same token (AA), it directs this request to the service Service-TCP-1. The following diagram illustrates this process.

Figure 1. How the Token Method Works

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure the Token load balancing method by using the command line interface

At the command prompt, type the following commands to configure the token load balancing method and verify the configuration:

```
set lb vserver <name> -lbMethod TOKEN -rule <rule> -datalength <length>
    -dataoffset <offset>

show lb vserver <name>
```

Example:

```
set lb vserver LB-VServer-1 -lbMethod TOKEN -rule 'AA' -datalength 2 -
   dataoffset 25

show lb vserver LB-VServer-1
```

To configure the token load balancing method by using the configuration utility

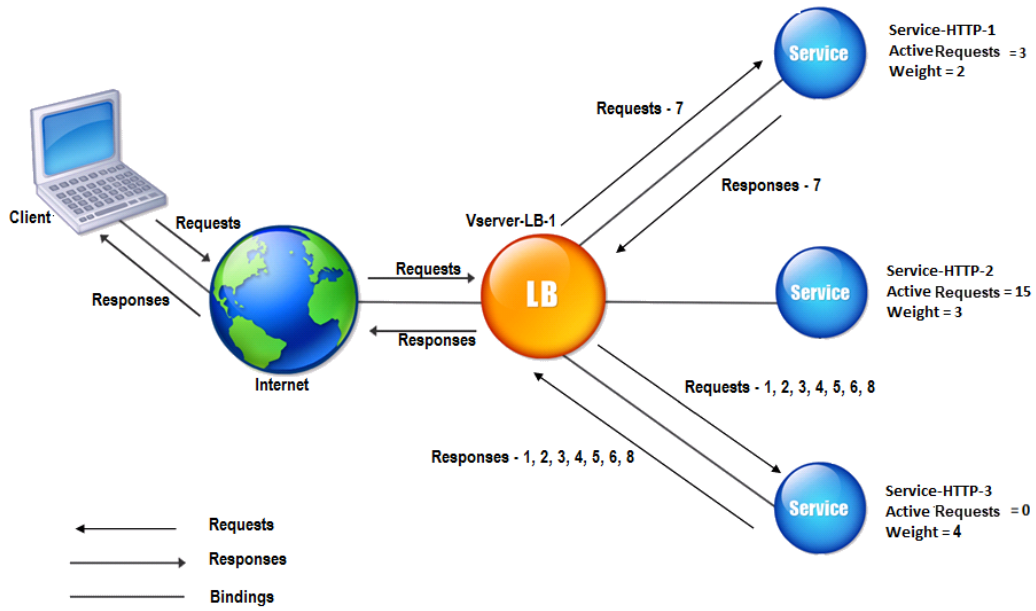
1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. In Advanced Settings, click Method
3. In the Load Balancing Method list, select Token, and specify an expression.

Least requests method

January 16, 2024



A load balancing virtual server configured to use the least request method selects the service that has received the fewest requests.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is handling 3 requests.
- Service-HTTP-2 is handling 15 requests.
- Service-HTTP-3 is not handling any requests.

The following diagram illustrates how NetScaler uses the least requests method to choose a service for each request that it receives.

Figure 1. How the Least Request Load Balancing Method Works

In this example, the virtual server selects the service for each incoming request by choosing the server with the fewest requests.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Requests are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any request.

  Note: The service with no request is selected first.
- Service-HTTP-3 receives the second and third requests because the service has the next least number of requests.
- Service-HTTP-1 receives the fourth request because Service-HTTP-1 and Service-HTTP-3 have the same number of requests, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. Then, NetScaler starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

> **Note:**
>
> If requests to Service-HTTP-2 is completed, it might get new request before each of the other two services has 15 requests.

The following table explains how requests are distributed among the services in the load balancing setup.

Incoming requests	Service selected	Current number of requests	Remarks
Request-1	Service-HTTP-3; (N = 0)	1	Service-HTTP-3 has the fewest requests.
Request-2	Service-HTTP-3; (N = 1)	2	Service-HTTP-3 has the fewest requests.
Request-3	Service-HTTP-3; (N = 2)	3	-
Request-4	Service-HTTP-1; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of requests.
Request-5	Service-HTTP-3; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of requests.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Incoming requests	Service selected	Current number of requests	Remarks
Request-6	Service-HTTP-1;(N = 4)	5	-
Request-7	Service-HTTP-3; (N = 4)	5	-
Request-8	Service-HTTP-1; (N = 5)	6	-

Service-HTTP-2 is selected for load balancing when it completes all the requests, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more requests each.

NetScaler can also use the least request method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

Nw = (Number of active requests) * (10000 / weight)

The following example shows how NetScaler selects a service for load balancing by using the least request method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Requests are forwarded as follows:

- Service-HTTP-3 receives the first request because the service is not handling any requests.

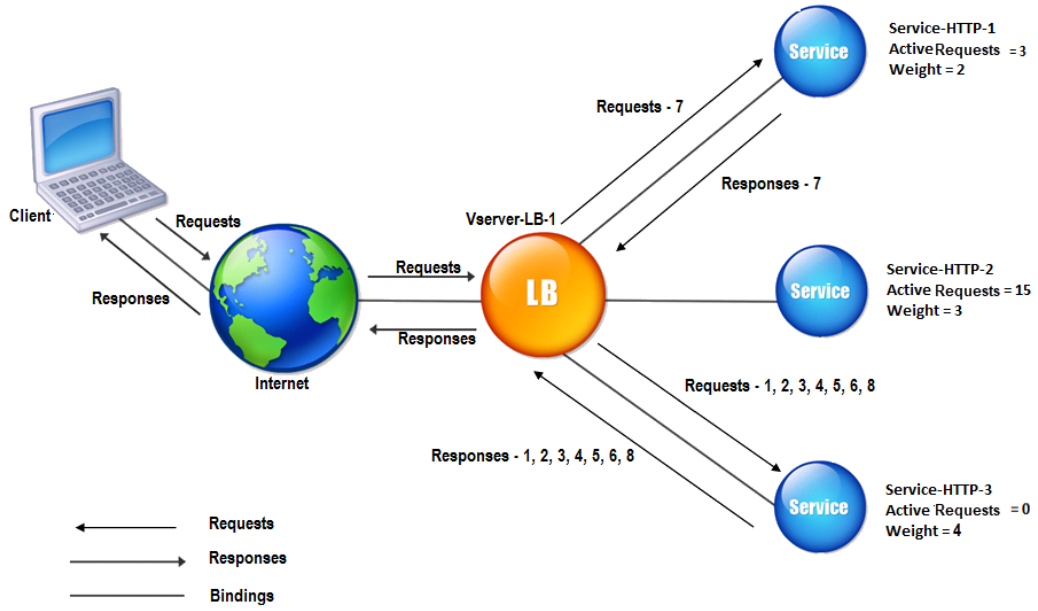
  Note: If the services are not handling any requests, NetScaler uses the round robin method regardless of the weights assigned to each of the services.

- Service-HTTP-3 receives the second, third, fourth, fifth, and sixth requests because the service has the lowest Nw value.
- Service-HTTP-1 receives the seventh request. Because Service-HTTP-1 and Service-HTTP-3 now have the same Nw value, the appliance performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the eighth request.

The following table explains how requests are distributed on the three-service load balancing setup that is described earlier.

Request Received	Service Selected	Current Nw (Number of requests) * (10000 / weight) value	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 2500	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 2500)	Nw = 5000	

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



Request Received	Service Selected	Current Nw (Number of requests) * (10000 / weight) value	Remarks
Request-3	Service-HTTP-3; (Nw = 5000)	Nw = 7500	
Request-4	Service-HTTP-3; (Nw = 7500)	Nw = 10000	
Request-5	Service-HTTP-3; (Nw = 10000)	Nw = 12500	
Request-6	Service-HTTP-3; (Nw = 12500)	Nw = 15000	
Request-7	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw values
Request-8	Service-HTTP-3; (Nw = 15000)	Nw = 17500	

Service-HTTP-2 is selected for load balancing when it completes its requests or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how NetScaler uses the least request method when weights are assigned to the services.

Figure 2. Mechanism of the Least Requests Load Balancing Method when Weights are Assigned

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure the least request method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Configure a load balancing method that does not include a policy

September 14, 2021

After you select a load balancing algorithm for your load balancing setup, you must configure the Citrix ADC appliance to use that algorithm. You can configure it by using the CLI or by using the configuration utility.

Note:

The token method is policy based and requires more configuration than is described here. To configure the token method, see Token method.

For some hash-based methods, you can mask an IP address to direct requests belonging to the same subnet to the same server. For more information, see Hashing methods.

To set the load balancing method by using the command line interface

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set lb vserver <name> -lbMethod <method>
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod LeastConnection
```

To set the load balancing method by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In Advanced Settings, click **Method**, and in the Load Balancing Method list, select a method.

Persistence and persistent connections

September 23, 2022

A load balancing stateless protocol, such as HTTP, disrupts the maintenance of state information about client connections if persistence is not configured. Different transmissions from the same client might be directed to different servers even though all the transmissions are part of the same session. You can configure persistence on a load balancing virtual server that handles certain types of Web applications, such as shopping cart applications.

Before you can configure persistence, you need to understand the different types of persistence, how they are used, and what their implications are. You then need to configure the Citrix ADC appliance to provide persistent connections for those websites and Web applications that require them.

You can also configure backup persistence, which takes effect if the primary type of persistence configured for a load balancing virtual server fails. You can configure persistence groups, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

For information about persistence with RADIUS load balancing, see Configuring RADIUS Load Balancing with Persistence.

About Persistence

September 14, 2021

You can choose from among any of several types of persistence for a given load balancing virtual server, which then routes to the same service all connections from the same user to your shopping

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

cart application, web-based email, or other network application. The persistence session remains in effect for the time which you specify.

If a server participating in a persistence session goes DOWN, the load balancing virtual server uses the configured load balancing method to select a new service, and establishes a new persistence session with the server represented by that service. If the server goes OUT OF SERVICE, it continues to process existing persistence sessions, but the virtual server does not direct any new traffic to it. After the shutdown period elapses, the virtual server ceases to direct connections from existing clients to the service, closes existing connections, and redirects those clients to new services if necessary.

Depending on the persistence type you configure, the Citrix ADC appliance might examine the source IPs, destination IPs, SSL session IDs, Host or URL headers, or some combination of these things to place each connection in the proper persistence session. It might also base persistence on a cookie issued by the Web server, on an arbitrarily assigned token, or on a logical rule. Almost anything that allows the appliance to match connections with the proper persistence session and is used as the basis for persistence.

The following table summarizes the persistence types available on the Citrix ADC appliance.

Persistence Type	Description
Source IP	SOURCEIP. Connections from the same client IP address are parts of the same persistence session.
HTTP Cookie	COOKIEINSERT. Connections that have the same HTTP Cookie header are parts of the same persistence session.
SSL Session ID	SSLSESSION. Connections that have the same SSL Session ID are parts of the same persistence session.
URL Passive	URLPASSIVE. Connections to the same URL are treated as parts of the same persistence session.
Custom Server ID	CUSTOMSERVERID. Connections with the same HTTP HOST header are treated as parts of the same persistence session.
Destination IP	DESTIP. Connections to the same destination IP are treated as parts of the same persistence session.
Source and Destination IPs	SRCIPDESTIP. Connections that are both from the same source IP and to the same destination IP are treated as parts of the same persistence session.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Persistence Type	Description
SIP Call ID	CALLID. Connections that have the same call ID in the SIP header are treated as parts of the same persistence session.
RTSP Session ID	RTSPSID. Connections that have the same RTSP Session ID are treated as parts of the same persistence session.
User-Defined Rule	RULE. Connections that match a user-defined rule are treated as parts of the same persistence session.

Table 1. Types of Persistence

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your Citrix ADC appliance. The following table shows which types of persistence fall into each category.

Persistence Type	Number of Simultaneous Persistent Connections Supported
Source IP, SSL Session ID, Rule, destination IP, source IP/destination IP, SIP Call ID, RTSP Session ID	250 K
Cookie, URL Server ID, Custom Server ID	Memory limit. In CookieInsert, if timeout is not 0, the number of connections is limited by memory.

Table 2. Persistence Types and Numbers of Simultaneous Connections Supported

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

Persistence Type	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge	SSL_TCP	RTSP	SIP_UDP
SOURCEIP	YES	YES	YES	YES	YES	YES	NO	NO
COOKIEINSERT	YES	YES	NO	NO	NO	NO	NO	NO
SSLSESSION	NO	YES	NO	NO	YES	YES	NO	NO

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Persistence Type	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge	SSL_TCP	RTSP	SIP_UDP
URLPASSIVE	YES	YES	NO	NO	NO	NO	NO	NO
CUSTOMSERVERID	YES	YES	NO	NO	NO	NO	NO	NO
RULE	YES	YES	YES	NO	NO		NO	NO
SRCIPDESTIP	YES	YES	YES	YES	YES	YES	NO	NO
DESTIP	YES	YES	YES	YES	YES	YES	NO	NO
CALLID	NO	NO	NO	NO	NO	NO	NO	YES
RTSPID	NO	NO	NO	NO	NO	NO	YES	NO

Table 3. Relationship of Persistence Type to Virtual Server Type

Source IP address persistence

September 14, 2021

When source IP persistence is configured, the load balancing virtual server uses the configured load balancing method to select a service for the initial request, and then uses the source IP address (client IP address) to identify subsequent requests from that client and send them to the same service. You can set a time-out value, which specifies the maximum inactivity period for the session. When the time-out value expires, the session is discarded, and the configured load balancing algorithm is used to select a new server.

Caution: In some circumstances, using persistence based on source IP address can overload your servers. All requests to a single website or application are routed through the single gateway to the Citrix ADC appliance, even though they are then redirected to multiple locations. In multiple proxy environments, client requests frequently have different source IP addresses even when they are sent from the same client, resulting in rapid multiplication of persistence sessions where a single session must be created. This issue is called the "Mega Proxy problem."You can use HTTP cookie-based persistence instead of Source IP-based persistence to prevent this from happening.

To configure persistence based on Source IP Address, see Configuring Persistence Types That Do Not Require a Rule.

Note: If all incoming traffic comes from behind a Network Address Translation (NAT) device or proxy, the traffic appears to the Citrix ADC appliance to come from a single source IP address. This prevents Source IP persistence from functioning properly. Where this is the case, you must select a different persistence type.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

HTTP cookie persistence

November 4, 2024

When HTTP cookie persistence is configured, the Citrix ADC appliance sets a cookie in the HTTP headers of the initial client request. The cookie contains the IP address and port of the service selected by the load balancing algorithm. As with any HTTP connection, the client then includes that cookie with any subsequent requests.

When the Citrix ADC appliance detects the cookie, it forwards the request to the service IP and port in the cookie, maintaining persistence for the connection. You can use this type of persistence with virtual servers of type HTTP or HTTPS. This persistence type does not consume any appliance resources and therefore can accommodate an unlimited number of persistent clients.

Note: If the client's Web browser is configured to refuse cookies, HTTP cookie-based persistence does not work. It might be advisable to configure a cookie check on the website, and warn clients that do not appear to be storing cookies properly that they need to enable cookies for the website if they want to use it.

The format of the cookie that the Citrix ADC appliance inserts is:

```
NSC_XXXX=<ServiceIP ><ServicePort>
```

Where:

- NSC_XXXX is the virtual server ID that is derived from the virtual server name.
- ServiceIP and ServicePort are encoded representations of the service IP address and service port, respectively. The IP address and port are encoded separately.

You can set a time-out value for this type of persistence to specify an inactivity period for the session. When the connection has been inactive for the specified period, the Citrix ADC appliance discards the persistence session. Any subsequent connection from the same client results in a new server being selected based on the configured load balancing method, and a new persistence session being established.

Note: If you set the time-out value to 0, the Citrix ADC appliance does not specify an expiration time, but sets a session cookie that is not saved when the client's browser is shut down.

By default, the Citrix ADC appliance sets HTTP version 0 cookies for maximum compatibility with client browsers. (Only certain HTTP proxies understand version 1 cookies; most commonly used browsers do not.) You can configure the appliance to set HTTP version 1 cookies, for compliance with RFC2109. For HTTP version 0 cookies, the appliance inserts the cookie expiration date and time as an absolute Coordinated Universal Time (GMT). It calculates this value as the sum of the current GMT time on the appliance and the time-out value. For HTTP version 1 cookies, the appliance inserts a relative

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

expiration time by setting the "Max-Age"attribute of the HTTP cookie. In this case, the client's browser calculates the actual expiration time.

To configure persistence based on a cookie inserted by the appliance, see Configuring Persistence Types That Do Not Require a Rule.

In the HTTP cookie, the appliance by default sets the `HTTPOnly` flag to indicate that the cookie is nonscriptable and must not be revealed to the client application. Therefore, a client-side script cannot access the cookie, and the client is not susceptible to cross-site scripting.

Certain browsers, however, do not support the `HTTPOnly` flag and, therefore, might not return the cookie. As a result, persistence is broken. For browsers that do not support the flag, you can omit the `HTTPOnly` flag in the persistence cookie.

To change the HTTPOnly flag setting by using the CLI

At the command prompt, type:

```
set lb parameter -httpOnlyCookieFlag (ENABLED|DISABLED)
```

Example:

```
>  set lb parameter -httpOnlyCookieFlag disabled
   Done
> show lb parameter
  Global LB parameters:
       Persistence Cookie HttpOnly Flag: DISABLED
       Use port for hash LB: YES
 Done
```

To change the HTTPOnly flag setting by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, and select or clear the **Persistence Cookie HTTPOnly** flag.

Encrypting the Cookie

From release 10.5 build 55.8, you can encrypt the cookie in addition to any SSL encryption.

To encrypt the cookie by using the command line interface, at the command prompt, type

```
set lb parameter -UseEncryptedPersistenceCookie ENABLED -
    cookiePassphrase test
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To encrypt the cookie by using the configuration utility

1. Navigate to **Traffic Management** > **Change Load Balancing Parameters**, and select **Encode Persistence Cookie Values** and enter a passphrase in **Cookie Passphrase**.

SSL session ID persistence

September 14, 2021

When SSL session ID persistence is configured, the Citrix ADC appliance uses the SSL session ID, which is part of the SSL handshake process, to create a persistence session before the initial request is directed to a service. The load balancing virtual server directs subsequent requests that have the same SSL session ID to the same service. This type of persistence is used for SSL bridge services.

Note:

There are two issues that users must consider before choosing this type of persistence. First, this type of persistence consumes resources on the Citrix ADC appliance, which limits the number of concurrent persistence sessions that it can support. If you expect to support multiple persistence sessions, you might want to choose another type of persistence.

Second, if the client and the load-balanced server must renegotiate the session ID during their transactions, persistence is not maintained, and a new persistence session is created when the client's next request is received. This might result in the client's activity on the website being interrupted and the client might be asked to reauthenticate or restart the session. It might also result in large numbers of abandoned sessions if the timeout is set to too large a value.

To configure persistence based on SSL session ID, see Configuring Persistence Types That Do Not Require a Rule.

> **Note**
>
> SSL session ID persistence is not supported with session tickets.

Back up persistence support for SSL session ID

From NetScaler release 12.0 build 56.20, source IP persistence is supported as a backup persistence type for SSL session ID persistence. If the client and load-balanced server renegotiate the session, and source IP persistence is configured as the backup persistence, client requests are forwarded to the same server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To support backup persistence for SSL session ID, the Citrix ADC appliance creates session entries for both source IP and SSL session ID when a client request is received for the first time. For the subsequent requests containing the same session ID, the SSL session ID is used. However, when the client and the load-balanced server renegotiate the session, the client request is forwarded to the same server by using the Source IP persistence and a new SSL Session ID persistence entry is created.

For information about configuring backup persistence, see Configuring Backup Persistence.

Diameter AVP number persistence

September 14, 2021

You can use persistence based on the Attribute-Value Pair (AVP) number of a Diameter message to create persistent Diameter sessions. When the Citrix ADC appliance finds the AVP in the Diameter message, it creates a persistence session based on the value of the AVP. All subsequent messages that match the value of the AVP are directed to the previously selected server. If the value of the AVP does not match the persistence session, a new session is created for the new value.

Note: If the AVP number is not defined in Diameter base-protocol RFC 6733, and if the number is nested inside a grouped AVP, you must define a sequence of AVP numbers (maximum of 3) in parent-to-child order. For example, if the persist AVP number X is nested inside AVP Y, which is nested in Z, define the list as Z Y X.

To configure Diameter-based persistence on a virtual server by using the command line interface

At the command prompt, type the following command:

```
set lb vserver <name> -PersistenceType <type-> persistAVPno <
    positive_integer>
```

Example:

```
set lb vserver diameter_vs -persistenceType DIAMETER -persistAVPno 263
```

Custom server ID persistence

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

In the Custom Server ID persistence method, the Server ID specified in the client request is used to maintain persistence. For this type of persistence to work, you must first set a server ID on the services. The Citrix ADC appliance checks the URL of the client request and connects to the server associated with the specified server ID. The service provider must make sure that the users are aware of the server IDs to be provided in their requests for specific services.

For example, if your site provides different types of data, such as images, text, and multimedia, from different servers, you can assign each server a server ID. On the Citrix ADC appliance, you specify those server IDs for the corresponding services, and you configure custom server ID persistence on the corresponding load balancing virtual server. When sending a request, the client inserts the server ID into the URL indicating the required type of data.

To configure custom server ID persistence:

- In your load balancing setup, assign a server ID to each service for which you want to use the user-defined server ID to maintain persistence. Alphanumeric server IDs are allowed.
- Specify rules, in the default-syntax expression language, to examine the URL queries for the server ID and forward traffic to the corresponding server.
- Configure custom server ID persistence.

Note: The persistence time-out value does not affect the Custom Server ID persistence type. There is no limit on the maximum number of persistent clients because this persistence type does not store any client information.

Example:

In a load balancing setup with two services, assign server ID 2345-photo-56789 to Service-1, and server ID 2345-drawing-abb123 to Service-2. Bind these services to a virtual server named Web11.

```
1 set service Service-1 10.102.29.5 -CustomServerID 2345-photo-56789
2
3 set service Service-2 10.102.29.6 -CustomServerID 2345-drawing-abb123
```

On virtual server Web11, enable Custom Server ID persistence.

Create the following expression so that all URL queries containing the string “sid=”are examined.

HTTP.REQ.URL.AFTER_STR(“sid=”)

Example:

```
1 set lb vserver Web11 -persistenceType customserverID -rule "HTTP.REQ.
     URL.AFTER_STR("sid=")"
2
3 bind lb vserver Web11 Service-[1-2]
```

When a client sends a request with the following URL to the IP address of Web11, the appliance directs the request to Service-2 and honors persistence.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
http://www.example.com/index.asp?&sid=2345-drawing-abb123
```

For more information about default-syntax policy expressions, see the Policy Configuration and Reference.

To configure custom server ID persistence by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open the service and set a server ID.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
4. In Advanced Settings, select Persistence.
5. Select CUSTOMESERVERID, and specify an expression.

IP address persistence

September 14, 2021

You can base persistence on Destination IP addresses, or on both Source IP and Destination IP Addresses.

Persistence Based on Destination IP Addresses

With destination IP address-based persistence, when the Citrix ADC appliance receives a request from a new client, it creates a persistence session based on the IP address of the service selected by the virtual server (the destination IP address). Later, it directs requests to the same destination IP to the same service. This type of persistence is used with link load balancing. For more information about link load balancing, see Link Load Balancing.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on the destination IP address, see Configuring Persistence Types That Do Not Require a Rule.

Persistence Based on Source and Destination IP Addresses

With source and destination IP address-based persistence, when the Citrix ADC appliance receives a request, it creates a persistence session based on both the IP address of the client (the source IP

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

address) and the IP address of the service selected by the virtual server (the destination IP address). Later, it directs requests from the same source IP and to the same destination IP to the same service.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on both source and destination IP addresses, see Configuring Persistence Types That Do Not Require a Rule.

SIP Call ID persistence

September 14, 2021

With SIP Call ID persistence, the Citrix ADC appliance chooses a service based on the call ID in the SIP header. This enables it to direct packets for a particular SIP session to the same service and, therefore, to the same load balanced server. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure persistence based on SIP Call ID, see Configuring Persistence Types That Do Not Require a Rule.

RTSP session ID persistence

September 14, 2021

With RTSP Session ID persistence, when the Citrix ADC appliance receives a request from a new client, it creates a persistence session based on the Real-Time Streaming Protocol (RTSP) session ID in the RTSP packet header, and then directs the request to the RTSP service selected by the configured load balancing method. It directs subsequent requests that contain the same session ID to the same service. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

Note: RTSP Session ID persistence is configured by default on RTSP virtual servers, and you cannot modify that setting.

Sometimes different RTSP servers issue the same session IDs. When this happens, unique sessions cannot be created between the client and the RTSP server by using only the RTSP session ID. If you have multiple RTSP servers that might issue the same session IDs, you can configure the appliance to append the server IP address and port to the session ID, creating a unique token that can be used to establish persistence. This is called session ID mapping.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure persistence based on RTSP Session IDs, see Configuring Persistence Types That Do Not Require a Rule.

Important: If you need to use session ID mapping, you must set the following parameter when configuring each service within the load balancing setup. Also, make sure that no non-persistent connections are routed through the RTSP virtual server.

Configure URL passive persistence

October 8, 2023

With URL Passive persistence, when the Citrix ADC appliance receives a request from a client, it extracts the server IP address-port information (expressed as a single hexadecimal number) from the client request.

URL passive persistence requires configuring an advanced expression that specifies the query element that contains the server IP address-port information. For more information about classic and advanced policy expressions, see Policies and Expressions.

The following expression configures the appliance to examine requests for URL queries that contain the string "urlp=", extract the server IP address-port information, convert it from a hexadecimal string to an IP and port number, and forward the request to the service configured with this IP address and port number.

HTTP.REQ.URL.AFTER_STR("urlp=")

If URL passive persistence is enabled and the previous expression is configured, a request with the following URL and server IP address-port string is directed to 10.102.29.10:80.

```
http://www.example.com/index.asp?&urlp=0A661D0A0050
```

The persistence time-out value does not affect this persistence type. Persistence is maintained as long as the server IP address-port information can be extracted from client requests. This persistence type does not consume any appliance resources, so it can accommodate an unlimited number of persistent clients.

To configure URL passive persistence, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule. You set the persistence type to URLPASSIVE. You then perform the following procedures.

To configure URL passive persistence by using the CLI

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set lb vserver <vserverName>  [-persistenceType <persistenceType>]  [-
    rule <expression>]
```

Example:

```
set lb vserver LB-VServer-1 -persistenceType URLPASSIVE –rule HTTP.REQ
    .URL.AFTER_STR( “ urlp= ” )
```

To configure persistence on a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

> **Note:**
>
> Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

Configure persistence based on user-defined rules

October 8, 2023

> **Warning:**
>
> The use of Classic expressions for the persistence rule in the load balancing feature is deprecated. However Classic expressions are removed and no longer available for the filter rule on the Citrix ADC appliance release 13.1 onwards.

When rule based persistence is configured, the Citrix ADC appliance creates a persistence session based on the contents of the matched rule before directing the request to the service selected by the configured load balancing method. Later, it directs all requests that match the rule to the same service. You can configure rule based persistence for services of type HTTP, SSL, RADIUS, ANY, TCP, and SSL_TCP.

Rule based persistence requires a classic or default syntax expression. You can use a classic expression to evaluate request headers, or you can use a default syntax expression to evaluate request headers, Web form data in a request, response headers, or response bodies. For example, you can use a classic expression to configure persistence based on the contents of the HTTP Host header. You can also use

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

a default syntax expression to configure persistence based on application session information in a response cookie or custom header. For more information on creating and using classic and default syntax expressions, see Policies and Expressions.

The expressions that you can configure depend on the type of service for which you are configuring rule based persistence. For example, certain RADIUS-specific expressions are not allowed for protocols other than RADIUS, and TCP-option based expressions are not allowed for service types other than the ANY type. For TCP and SSL_TCP service types, you can use expressions that evaluate TCP/IP protocol data, Layer 2 data, TCP options, and TCP payloads.

Note: For a use case that involves configuring rule based persistence based on Financial Information eXchange ("FIX") Protocol data transmitted over TCP, see Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream.

Rule based persistence can be used for maintaining persistence with entities such as Citrix SD-WAN appliances, Citrix SD-WAN plug-ins, cache servers, and application servers.

Note: On an ANY virtual server, you cannot configure rule-based persistence for the responses.

To configure persistence based on a user-defined rule, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule, and set the persistence type to RULE. You can then perform the following procedures. You can configure rule based persistence by using the configuration utility or the CLI.

To configure persistence based on user-defined rules by using the CLI

At the command prompt, type:

```
set lb vserver <vserverName> [-rule <expression>][-resRule <expression
    >]
```

Example:

```
set lb vserver vsvr_name –rule http.req.header("cookie").value(0).
    typecast_nvlist_t('=',';').value("server")

set lb vserver vsvr_name –resrule http.res.header("set-cookie").value
    (0).typecast_nvlist_t('=',';').value("server")
```

To configure persistence based on user-defined rules by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

> **Note**
>
> Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

Example: Classic Expression for a Request Payload

The following classic expression creates a persistence session based on the presence of a User-Agent HTTP header that contains the string, "MyBrowser", and directs any subsequent client requests that contain this header and string to the same server that was selected for the initial request.

```
1 http header User-Agent contains MyBrowser
```

Example: Default syntax Expression for a Request Header

The following default syntax expression does the same thing as the previous classic expression.

HTTP.REQ.HEADER("User-Agent").CONTAINS ("MyBrowser")

Example: Default syntax Expression for a Response Cookie

The following expression examines responses for "server"cookies, and then directs any requests that contain that cookie to the same server that was selected for the initial request.

HTTP.RES.HEADER("SET-COOKIE").VALUE(0).TYPECAST_NVLIST_T('=',';').VALUE("server")

Configure persistence types that do not require a rule

October 8, 2023

To configure persistence, you must first set up a load balancing virtual server, as described in Setting Up Basic Load Balancing. You then configure persistence on the virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure persistence on a virtual server by using the CLI

At the command prompt, type the following commands to configure persistence and verify the configuration:

```
set lb vserver <name> -PersistenceType <type> [-timeout <integer>]

show lb vserver
```

Example:

```
set lb vserver Vserver-LB-1 -persistenceType SOURCEIP -timeout 60

show lb vserver
```

Timeout is the time period for which a persistence session is in effect. The timeout default and minimum values (in minutes) vary based on the persistence type as listed in the following table.

persistence type	Default value	Minimum value	Maximum value
Cookie insert/group cookie insert	2	0	1440
Other persistence types	2	2	1440

> **Note**
>
> - Group cookie insert persistence type can be set on the load balancing group.
> - For IP-based persistence, you can also set the persistMask parameter.
> - The persistence type by default is set to NONE.

To configure persistence on a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the **Others** list.

> **Note** Prior to Citrix ADC release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure backup persistence

September 14, 2021

You can configure a virtual server to use the source IP persistence type when the primary persistence type fails.

The following table describes the combinations of primary and secondary backup persistence types, and the conditions when the backup persistence is used.

Primary persistence	Backup persistence	When the primary persistence lookup fails…
Cookie Insert	Source IP	The appliance falls back to source-IP based persistence only when the client browser does not return any cookie in the request. However, if the browser returns a cookie (not necessarily the persistence cookie) it is assumed that the browser supports cookies and hence backup persistence is not triggered.
Rule	Source IP	The appliance uses source-IP based persistence when the parameter specified in the rule is missing in the incoming request.

Note

- If the primary persistence type is HTTP-cookie based persistence, and the backup persistence type is Source IP-based, you can set a timeout value for backup persistence. For instructions, see Setting a Timeout Value for Idle Client Connections.
- You cannot set a timeout value for backup persistence when the primary persistence is rule based, because in that case the timeout value for secondary persistence must be the same as for the primary persistence. Therefore, the primary and secondary expire at the same time.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set backup persistence for a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -persistenceType <PersistenceType> -
    persistenceBackup <BackupPersistenceType>
```

Example:

```
set lb vserver Vserver-LB-1 -persistenceType CookieInsert -
    persistenceBackup SourceIP

set lb vserver Vserver-LB-1 -persistenceType sslsession -
    persistenceBackup SourceIP

set lb vserver Vserver-LB-1  –persistenceType RULE  –rule http.req.
    header("User-Agent").value(0).contains("MyBrowser")  –
    persistenceBackup SOURCEIP

set lb vserver Vserver-LB-1 -persistenceType sslsession -
    persistenceBackup SourceIP
```

To set backup persistence for a virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In **Advanced Settings**, select **Persistence**, and specify a backup persistence type.

Note: The primary persistence must be set to COOKIEINSERT, RULE, or SSLSESSION.

Configure persistence groups

September 14, 2021

When you have load-balanced servers that handle several different types of connections (such as Web servers that host multimedia), you can configure a virtual server group to handle these connections. To create a virtual server group, you bind different types of virtual servers, one for each type of connection that your load balanced servers accept, into a single group. You then configure a persistence type for the entire group.

You can configure either source IP-based persistence or HTTP cookie-based persistence for persistence groups. After you set persistence for the entire group, you cannot change it for individual virtual servers in the group. If you configure persistence on a group and then add a new virtual server to the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

group, the persistence of the new virtual server is changed to match the persistence setting of the group.

When persistence is configured on a group of virtual servers, persistence sessions are created for initial requests, and subsequent requests are directed to the same service as initial request, regardless of the virtual server in the group that receives each client request.

When you add a virtual server that has persistence sessions to a load balancing group with a different persistence type, the existing persistent sessions specific to an old persistence type are deleted. The persistent sessions decide whether the traffic must go to the same virtual server or to a different server. Therefore, existing established connections are not impacted.

The persistence type of a load balancing group is applied to all the virtual servers bound to that group, irrespective of the virtual servers' protocol type. A load balancing group supports the following persistence types:

- SourceIP
- CookieInsert
- Rule

Some virtual servers support only certain persistence types. For example, a virtual server of type SSL_BRIDGE can use only SourceIP persistence type for an LB group.

If you configure HTTP cookie-based persistence, the domain attribute of the HTTP cookie is set. This setting causes the client software to add the HTTP cookie into client requests if different virtual servers have different public host names. For more information about CookieInsert persistence type, see Persistence Based on HTTP Cookies.

To create a virtual server persistency group by using the command line interface

At the command prompt, type:

```
bind lb group <vServerGroupName> <vServerName> -persistenceType <
    PersistenceType>
```

Example:

```
bind lb group Vserver-Group-1 Vserver-LB-1 -persistenceType
    CookieInsert
```

To modify a virtual server group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Persistency Groups**, create a persistency group, and specify the virtual servers that must be part of this group.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To modify a virtual server group by using the command line interface

At the command prompt, type:

```
set lb group <vServerGroupName> -PersistenceBackup <
    BackupPersistenceType> -persistMask <SubnetMaskAddress>
```

Example:

```
set lb group vserver-Group-1 -PersistenceBackup SourceIP -persistMask
    255.255.255.255
```

Share persistent sessions between virtual servers

September 14, 2021

In some customer environments (telecom and ISP), a single server handles both control and data traffic. For a given client IP address, both control and data traffic have to be directed to the same back-end server. For this, one virtual server is required for handling client authentication traffic, and usually rule based persistency is configured on it. For example, Radius.req.avp(8).value.typecast_text_t'. The second virtual server for handling data traffic. Usually, SourceIP persistence is configured on it.

Previously, persistence entries were local to the virtual server. If you had to apply persistence across multiple virtual servers, you had to add the virtual server to a load balancing group and then apply a common persistence type to the group. This requirement cannot be achieved, because all the virtual servers bound to a load balancing group inherited the persistency configured on the group.

With the persistency sharing between virtual server feature, you can set the new `useVserverPersistency` parameter for a load balancing group to allow the virtual server in the group to use their own persistency parameters instead of inheriting them from the group settings. You can configure separate rule-based persistency on each virtual server.

Optionally, you can also designate one of the virtual servers in the group as a main virtual server. When a virtual server is designated as a main virtual server, only that virtual server creates the persistence entries, which are used by all the virtual server in the group. If the main virtual server is down, the Citrix ADC appliance does not create any persistence entries.

Note: Persistence sharing across the virtual servers is supported only for rule based persistency methods. Configure compatible rule based persistence parameters on the member virtual servers.

Example:

Assume v1 and v2 are bound to a load balancing group, v1 is a RADIUS type virtual server and v2 is an HTTP type virtual server. 'Radius.req.avp(8).value.typecast_text_t'persistency is configured on v1 and 'client.ip.src'is configured on v2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

When traffic flows through the RADIUS virtual server v1, it creates a persistent entry based on the evaluated rule string. Later, when traffic reaches the HTTP type virtual server v2, v2 checks for the persistence entries on the load balancing group and uses the same persistence session to direct traffic to the same back-end server.

Configuring Sharing of Persistent Sessions

To share persistency parameters across the virtual server in a load balancing group, you must first enable the useVserverPersistency parameter and then designate one of the virtual servers in the group as a main server.

To enable the useVserverPersistency parameter by using the command line interface

At the command prompt, type:

```
set lb group <name> -useVserverPersistency ( ENABLED)
```

Example:

```
set lb group lb_grp1 -useVserverPersistency ENABLED
```

To enable the useVserverPersistency parameter by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.
3. Select **Use Vserver Persistence**.

To designate a virtual server as a main virtual server by using the command line interface

At the command prompt, type:

```
set lb group <name> -useVserverPersistency ( ENABLED ) -masterVserver <
    string>
```

Example:

```
set lb group lb_grp1 -useVserverPersistency ENABLED – masterVserver vs1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To designate a virtual server as a main virtual server by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.
3. Select **Use Vserver Persistence**.
4. In the **Virtual Server Name** box, click **+** to add the virtual server to the group. You can select the available virtual server or create a virtual server.
5. Click **Create** if you are adding a new group or **Close** if you are modifying an existing group.
6. Select the group for which you have enabled the useVserverPersistency parameter and click **Edit** to set a virtual server as a main to create persistence entries.
7. From the **Master vServer** list, select the virtual server that has to be designated as a main virtual server.

Arguments

useVserverPersistency

Allow the virtual servers in a group to use their own persistency parameters to create persistent sessions, instead of inheriting the persistency settings from the group settings. When this parameter is enabled, persistence cannot be set on the load balancing group.

When this parameter is disabled, the group's virtual servers inherit the persistency parameters from the group settings.

When this parameter is toggled on the load balancing group, the Citrix ADC appliance flushes all the corresponding persistence entries of the group and the member virtual servers.

Possible values: ENABLED, DISABLED

Default: DISABLED

Example:

```
set lb group lb_grp1 -useVserverPersistency ENABLED
```

masterVserver

Designate a virtual server as a main virtual server in its load balancing group. Once designated, only the main virtual server can create the persistent entries used by the group.

Note: This parameter can be set only if the useVserverPersistency parameter is enabled.

Example:

```
set lb group lb_grp1 –masterVserver vs1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example Configuration of Sharing Persistent Sessions by Using the Command Line Interface

The virtual servers are created

```
add lb vs vs1 http 10.1.10.11 80 -persistence rule -rule 'client.ip.src'

add lb vs vs2 radius 10.2.2.2 1812 -persistenceType rule -rule 'Radius.req.avp(8).value.typecast_text_t'
```

The groups are created.

```
add lb group lb_grp1 -persistenceType NONE -useVserverPersistency ENABLED
```

A virtual server in a group is designated as the main virtual server.

```
set lb group lb_grp1 -masterVserver vs1
```

The virtual servers are bound to the group.

```
bind lb group lb_grp1 vs1
bind lb group lb_grp1 vs2
```

For more details, see Setting Up Basic Load Balancing and Configuring Persistence Groups.

Configure RADIUS load balancing with persistence

September 14, 2021

Today's complex networking environment often requires coordinating a high-volume, high-capacity load balancing configuration with robust authentication and authorization. Application users might connect to a VPN through mobile access points such as consumer-grade DSL or Cable connections, WiFi, or even dial-up nodes. Those connections usually use dynamic IPs, which can change during the connection.

If you configure RADIUS load balancing on the Citrix ADC appliance to support persistent client connections to RADIUS authentication servers, the appliance uses the user logon or the specified RADIUS attribute instead of the client IP as the session ID, directing all connections and records associated with that user session to the same RADIUS server. Users are therefore able to log on to your VPN from mobile access locations without experiencing disconnections when the client IP or WiFi access point changes.

To configure RADIUS load balancing with persistence, you must first configure RADIUS authentication for your VPN. For information and instructions, see the Authentication, Authorization, Auditing (AAA)

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

chapter in AAA Application Traffic. Also choose either the Load Balancing or Content Switching feature as the basis for your configuration, and make sure that the feature you chose is enabled. The configuration process with either feature is almost the same.

Then, you configure either two load balancing, or two content switching, virtual servers, one to handle RADIUS authentication traffic and the other to handle RADIUS accounting traffic. Next, you configure two services, one for each load balancing virtual server, and bind each load balancing virtual server to its service. Finally, you create a load balancing persistency group and set the persistency type to RULE.

Enabling the Load Balancing or Content Switching Feature

To use the Load Balancing or Content Switching feature, you must first ensure that the feature is enabled. If you are configuring a new Citrix ADC appliance that has not previously been configured, both of these features are already enabled, so you can skip to the next section. If you are configuring a Citrix ADC appliance with a previous configuration on it, and you are not certain that the feature you use is enabled, you must do that now.

- For instructions on enabling the load balancing feature, see Enabling Load Balancing.
- For instructions on enabling the content switching feature, see Enabling Content Switching

Configuring Virtual Servers

After enabling the load balancing or content switching feature, you must next configure two virtual servers to support RADIUS authentication:

- **RADIUS authentication virtual server.** This virtual server and its associated service handles authentication traffic to your RADIUS server. Authentication traffic consists of connections associated with users logging onto your protected application or virtual private network (VPN).
- **RADIUS accounting virtual server.** This virtual server and its associated service handles accounting connections to your RADIUS server. Accounting traffic consists of connections that track an authenticated user's activities on your protected application or VPN.

Important: You must create either a pair of load balancing virtual servers or a pair of content switching virtual servers to use in your RADIUS persistence configuration. You cannot mix virtual server types.

To configure a load balancing virtual server by using the command line interface

At the command prompt type the following commands to create a load balancing virtual server and verify the configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add lb vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule
    <rule>

show lb vserver <name>
```

To configure an existing load balancing virtual server, replace the preceding `add lb virtual server` command with the `set lb vserver` command, which takes the same arguments.

To configure a content switching virtual server by using the command line interface

At the command prompt type the following commands to create a content switching virtual server and verify the configuration:

```
add cs vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule
    <rule>

show cs vserver <name>
```

To configure an existing content switching virtual server, replace the preceding `add cs vserver` command with the `set cs vserver` command, which takes the same arguments.

Example:

```
add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
    TOKEN -rule CLIENT.UDP.RADIUS.USERNAME

add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod
    TOKEN -rule CLIENT.UDP.RADIUS.USERNAME

set lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
    TOKEN -rule CLIENT.UDP.RADIUS.USERNAME

set lb vserver radius_auth_vs1 RADIUS 192.168.46.34 1813 -lbmethod
    TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
```

To configure a load balancing or content switching virtual server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Virtual Servers** or navigate to **Traffic Management > Content Switching > Virtual Servers»**, and configure a virtual server.

Configuring Services

After configuring your virtual servers, you must next configure two services, one for each of the virtual servers that you created.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: Once configured, these services are in the DISABLED state until the Citrix ADC appliance can connect to your RADIUS server's authentication and accounting IPs and monitor their status. For instructions, see Configuring Services.

Binding Virtual Servers to Services

After configuring your services, you must next bind each of the virtual servers that you created to the appropriate service.For instructions, see Binding Services to the Virtual Server.

Configuring a Persistency Group for Radius

After binding your load balancing virtual servers to the corresponding services, you must set up your RADIUS load balancing configuration to support persistence. To do so, you configure a load balancing persistency group that contains your RADIUS load balancing virtual servers and services, and configure that load balancing persistency group to use rule-based persistence. A persistency group is required because the authentication and accounting virtual servers are different and both the authentication & accounting message for a single user should reach the same RADIUS server. Persistency group enables to use the same session for both virtual servers. For instructions, see Configuring Persistence Groups.

Configuring RADIUS Shared Secret

From release 12.0, a Citrix ADC appliance supports RADIUS shared secret. A RADIUS client and server communicate with each other by using a shared secret that is configured on the client and on the server. Transactions between a RADIUS client and server are authenticated by using a shared secret. This secret is also used to encrypt some of the information in the RADIUS packet.

RADIUS shared secret key validation scenarios

The validation of the **RADIUS shared secret** key happens in the following scenarios:

- **RADIUS shared secret key is configured for both the radius client and the radius server:** The Citrix ADC appliance uses the RADIUS secret key for both the client side and the server side. If the verification succeeds, the appliance allows the RADIUS message to go through. Otherwise, it drops the RADIUS message.
- **RADIUS shared secret key is not configured for either the radius client or the radius server:** The Citrix ADC appliance drops the RADIUS message, because shared-secret-key validation cannot be performed on a node that has no radkey configured.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **RADIUS shared secret key is not configured for both the RADIUS client and the RADIUS server:** The Citrix ADC appliance bypasses the RADIUS secret key validation and allows the RADIUS messages to go through.

You can configure a default RADIUS shared secret or configure on a per client or a subnet basis. It is recommended to add a RADIUS shared secret key for all deployments with RADIUS policy configured. The appliance uses the source IP address of the RADIUS packet to decide which shared secret to use. You might configure a RADIUS client and server and the corresponding shared secret as follows:

At the CLI prompt, type:

```
add radiusNode <clientPrefix/Subnet> -radKey <Shared_secret_key>
```

Arguments

IPaddress IP address or subnet of the RADIUS client in CIDR format. The appliance uses the source IP address of an incoming request packet to match the client IP address. Instead of configuring a client IP address, you can configure the client network address. Longest prefix is matched to identify the shared secret for an incoming client request.

Radkey Shared secret between the client, Citrix ADC appliance, and the server. Maximum length: 31.

```
add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
    TOKEN -rule CLIENT.UDP.RADIUS.USERNAME

add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod
    TOKEN -rule CLIENT.UDP.RADIUS.USERNAME

add service radius_auth_service1 192.168.41.68 RADIUS 1812

add service radius_acct_service1 192.168.41.70 RADIUS 1813

bind lb vserver radius_auth_vs1 radius_auth_service1

bind lb vserver radius_acct_vs1 radius_acct_service[1-3]

add radiusNode 192.168.41.0/24 -radKey  serverkey123

add radiusNode 203.0.113.0/24 -radkey clientkey123
```

A shared secret must be configured both for a RADIUS client and server. The command is the same. The subnet determines whether the shared secret is for a client or for a server.

For example, if the subnet specified is a client subnet, the shared secret is for the client. If the subnet specified is a server subnet (192.168.41.0/24 in the earlier example), the shared secret is for the server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

A subnet of 0.0.0.0/0 implies that it is the default shared secret for all clients and servers.

> **Note:**
>
> Only the PAP and CHAP authentication methods are supported with RADIUS shared secret.

View persistence sessions

September 14, 2021

You can view the different persistence sessions that are in effect globally or for a particular virtual server.

> **Note**: A Citrix ADC nCore appliance uses multiple CPU cores for packet handling. The CPU core owns every session on the appliance. If the appliance receives a request for which a session does not exist, a session is created, and one of the cores is designated as the owner of that session.
>
> Subsequent requests that belong to that session might not always arrive at and be handled by the owner core. In that case, inter-core messaging ensures that the session information on the owner core is always current.

However, when a core receives a request that belongs to a persistence session owned by another core, the inter-core messaging does not refresh the timeout value for the persistence session.

Therefore, in the output of successively run show lb persistentSessions commands, which display timeout values from owner cores only, the timeout value for a persistence session might diminish to 0 (zero), even if the persistence session remains active.

To view persistence sessions by using the command line interface

At the command prompt, to view persistence sessions related to all virtual servers, type:

```
show lb persistentSessions [<vServer>]
```

At the command prompt, to view persistence sessions related a virtual server, type:

```
show lb persistentSessions <vServername>
```

Example:

```
show lb persistentSessions myVserver
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To view persistence sessions by using the GUI

Navigate to **Traffic Management** > **Virtual server persistent sessions**.

Clear persistence sessions

September 14, 2021

You might need to clear persistence sessions from the Citrix ADC appliance if sessions fail to time out. You can do one of the following:

- Clear all sessions for all virtual servers at once.
- Clear all sessions for a given virtual server at once.
- Clear a particular session that is associated with a given virtual server.

To clear a persistence session by using the command line interface

At the command prompt, type the following commands to clear persistence sessions and verify the configuration:

```
clear lb persistentSessions [<vServer> [-persistenceParam <string>]]

show persistentSessions <vServer>
```

Examples:

Example 1 clears all persistence sessions for load balancing virtual server lbvip1.

Example 2 first displays the persistence sessions for load balancing virtual server lbvip1, clears the session with the persistence parameter xls, and then displays the persistence sessions to verify that the session was cleared.

Example 1:

```
> clear persistentSessions lbvip1
 Done
> show persistentSessions
 Done
>
```

Example 2:

```
> show persistentSessions lbvip1
Type        SRC-IP    ...    PERSISTENCE-PARAMETER
RULE        0.0.0.0   ...    xls
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
RULE        0.0.0.0    ...    txt
RULE        0.0.0.0    ...    html
 Done
> clear persistentSessions lbvip1 -persistenceParam xls
 Done
> show persistentSessions lbvip1
Type        SRC-IP     ...    PERSISTENCE-PARAMETER
RULE        0.0.0.0    ...    txt
RULE        0.0.0.0    ...    html
 Done
>
```

To clear persistence sessions by using the configuration utility

1. Navigate to **Traffic Management > Clear Persistent Sessions**.

Override persistence settings for overloaded services

September 14, 2021

When a service is loaded or is otherwise unavailable, service to clients is degraded. In this case, you might have to configure the Citrix ADC appliance to temporarily forward to other services the requests that would otherwise be included in the persistence session that is associated with the overloaded service. In other words, you might have to override the persistence setting that is configured for the load balancing virtual server. You can achieve this functionality by setting the skippersistency parameter. When this skippersistence parameter is set, and if the virtual server receives new connections for an overloaded service, the following happens.

- The virtual server disregards any existing persistence sessions that are associated with that service, until the service returns to a state at which it can accept requests.
- Persistence sessions associated with other services are not affected.

This functionality is available for only virtual servers whose type is ANY or UDP.

In Branch Repeater load balancing configurations, you must also configure a load monitor and bind it to the service. The monitor takes the service out of subsequent load balancing decisions until the load on the service is brought below the configured threshold. For information about configuring a load monitor for your virtual server, see Understanding Load Monitors.

You can configure the virtual server to perform one of the following actions with the requests that would otherwise form a part of the persistence session:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Send each request to one of the other services.** The virtual server takes a load balancing decision and sends each request to one of the other services based on the load balancing method. If all the services are overloaded, requests are dropped until a service becomes available.

  Both wildcard and IP address–based virtual servers support this option. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances or firewalls.

- **Bypass the virtual server-service configuration.** The virtual server does not take a load balancing decision. Instead, it simply bridges each request through to a physical server based on the destination IP address in the request.

  Only wildcard virtual servers of type ANY and UDP support the bypass option. Wildcard virtual servers have a *:* IP and port combination. This action is appropriate for deployments in which you are using the virtual server to load balance Branch Repeater appliances or firewalls. In these deployments, the Citrix ADC appliance first forwards a request to a Branch Repeater appliance or firewall, and then forwards the processed response to a physical server. The virtual server sends requests directly to their destination IP addresses in the following conditions.

  - You configure the virtual server to bypass the virtual server–service configuration for overloaded services.
  - The Branch Repeater appliance or firewall gets overloaded.

  The virtual server sends requests directly to their destination IP addresses until the Branch Repeater appliance or firewall can accept requests.

To override persistence settings for overloaded services by using the CLI

At the command prompt, type the following commands to override persistence settings for overloaded services and verify the configuration:

```
set lb vserver <name> -skippersistency <skippersistency>

show lb vserver <name>
```

Example

```
> set lb vserver mylbvserver -skippersistency ReLb
 Done
> show lb vserver mylbvserver
    mylbvserver (*:*) - ANY Type: ADDRESS
       . . .
       . . .
 Skip Persistency: ReLb
       . . .
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
 9   Done
10  >
```

To override persistence settings for overloaded services by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server of type UDP or ANY.
2. In the Advanced Settings pane, select Traffic Settings, and specify the type of Skip Persistency.

Troubleshooting

September 14, 2021

- **The statistics from the Citrix ADC VPX appliance indicate that the appliance has reached the session persistence limit. As a result, persistence sessions are failing. Is possible to increase the session persistence limit?**

  Cause: The Citrix ADC appliance has the system limit of 250,000 persistence session for a core.

  Resolution: To resolve this issue, you can perform any of the following tasks:

  - Reduce the time-out value for persistence
  - Increase the number of cores for the appliance

- **After configuring Cookie Insert persistence on the Citrix ADC appliance, the users report that the connections work fine for some time, but then start getting disconnected. What best practice should I follow when configuring persistence?**

  Cause: By default, the time-out value for Cookie Insert persistence is 120 seconds.

  Resolution: When you configure persistence for applications for which idle time cannot be determined, set the Cookie Insert persistence time-out value to 0. With this setting, the connection does not time out.

- **After configuring an HTTP virtual server on the Citrix ADC appliance, I need to make sure that a user always connects to the same server for the requested content, so I configured SourceIP persistence. Now, increasing the time-out value for persistence introduces latency. How can I increase the timeout value without affecting performance?**

  Resolution: Consider using Cookie Insert persistence with the time-out value set to 0. This setting enables long-duration persistence settings, because the appliance does not specify a time for expiring the cookie.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **After configuring Cookie Insert persistence on the Citrix ADC appliance, it works as expected when clients from the same time zone access the content. However, when a client from another time zone makes an attempt to connect, the connection is immediately timed out.**

  Cause: Time based Cookie Insert persistence works as expected when a client from the same time zone makes a connection. However, when the client machine and Citrix ADC appliance are in different time zones, the cookie is not valid. For example, when a client in the EST time zone sends a cookie at 11:00 AM EST to a Citrix ADC appliance in the PST time zone, the appliance receives the cookie at 2:00 PM PST. As a result of the difference in time, the cookie is not valid, and the connection is immediately timed-out.

  Resolution: Set the time-out value for Cookie Insert persistence to 0.

- **A Citrix ADC appliance is used to load balance application servers, such as Oracle Weblogic server. To make sure that clients get persistent connections to these servers, SourceIP persistence is configured. It works as expected when a connection is made from a computer. However, when thin clients attempt a connection through a terminal server and, as a result, the appliance receives requests from multiple clients from the same IP address (the terminal server IP address). Therefore, the connections from all thin clients are directed to the same application server. Is it possible to configure persistency for requests from individual thin clients based on the client IP address?**

  Cause: The Citrix ADC appliance receives requests from the terminal server and the source IP address of the request remains the same. As a result, the appliance cannot distinguish among the requests received from the thin clients and provide persistence according to the requests from thin clients.

  Resolution: To avoid this problem, you can configure Rule persistence based on some unique parameter value for each thin client.

- **The Citrix ADC appliance is used to load balance Web Interface servers. When accessing the servers, the user receives the "State Error"error message. Additionally, when one of the Web Interface servers is shut down or not available, some of the users receive an error message.**

  Cause: Lack of persistence to the Web Interface servers can result in error messages when a user attempts to connect to the server.

  Resolution: Citrix recommends that you specify the Cookie Insert persistence method on the Citrix ADC appliance when load balancing Web Interface servers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Insert cookie attributes to ADC generated cookies

October 16, 2023

The web administrators can insert other cookie attributes to the cookies generated by the Citrix ADC appliance. These additional cookie attributes help in enforcing the required policies for the ADC generated cookies based on the application access pattern.

The following features use the ADC generated cookies to achieve persistency.

- Load balancing cookie persistence
- Load balancing group cookie persistence
- GSLB site persistence
- Content switching cookie persistence

You can insert other cookie attributes to the ADC generated cookies using the following parameters:

- **LiteralADCCookieAttribute:** Append other cookie attributes to the ADC generated cookie, as a string.
- **ComputedADCCookieAttribute:** Use an ADC ns variable to conditionally append cookie attributes to the ADC generated cookie, based on the client or server attributes, for example, user agent version.

> **Note**
>
> You cannot configure both Literal ADC Cookie Attribute and Computed ADC Cookie Attribute, simultaneously on the load balancing parameter or in a single load balancing profile.

Use case: Configure SameSite cookie attribute

Every cookie has a domain associated with it. When a cookie's domain matches the website domain in the user's address bar, this is considered a same-site (or first party) context. If the domain associated with a cookie matches an external service and not the website in the user's address bar, this is considered a cross-site (or third party) context.

The **SameSite** attribute indicates the browser whether the cookie can be used for cross-site context or only for same-site context. Also, if an application intends to be accessed in the cross-site context then it can do so only via the HTTPS connection. For details, see RFC6265.

Until Feb 2020, the **SameSite** property was not explicitly set in Citrix ADC. The browser took the default value as None, and did not impact the Citrix ADC deployments.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

However with certain browsers upgrade, such as Google Chrome 80, there is a change in the default cross-domain behavior of cookies. The **SameSite** attribute can be set to one of the following values. Default value for Google Chrome is set to Lax.

- **None:** Indicates the browser to use a cookie in cross-site context only on secure connections.
- **Lax:** Indicates the browser to use a cookie for requests in the same-site context. In the cross-site context, only safe HTTP methods like GET request can use the cookie.
- **Strict:** Use the cookie only in the same-site context.

If there is no SameSite attribute in the cookie, the Google Chrome assumes the functionality of Same-Site=Lax.

> **Note**
>
> For certain version of other browsers, the default value for the SameSite attribute might be set to **None**. In some browser versions, "SameSite = none"can be treated differently. For example, the following browsers reject a cookie with "SameSite = none":
>
> - Versions of Chrome from Chrome 51 to Chrome 66 (inclusive on both ends)
> - Versions of UC browser on Android earlier to version 12.13.2

Configure ADC generated cookies

To configure ADC generated cookie attributes, you must perform the following:

1. Create a load balancing virtual server
2. Set the ADC Cookie attributes for the load balancing virtual server, either through LB parameters or LB profile.
3. If you use an LB profile, set the LB profile to a load balancing virtual server.
4. If you choose to use the Computed ADC Cookie Attribute, configure the related rewrite policy.

> **Note**
>
> If an LB profile is bound to an LB virtual server, then the profile parameter configuration is considered instead of the global LB parameter configuration.

You can set the ADC generated cookie attributes by the following methods:

- Setting the ADC cookie attributes in load balancing parameters
- Setting the ADC cookie attributes in the load balancing profile

Setting the ADC cookie attributes in the load balancing parameters by using the CLI

To apply a policy uniformly to ADC generated cookies of all applications configured on the Citrix ADC appliance, you can set the ADC cookie attribute in the global LB parameters.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The **Literal ADC Cookie Attribute** setting allows you to unconditionally insert the cookie attributes to the ADC generated cookie.

At the command prompt, type:

```
set lb parameter -LiteralADCCookieAttribute <string>
```

Example:

```
set lb parameter -LiteralADCCookieAttribute SameSite=None
```

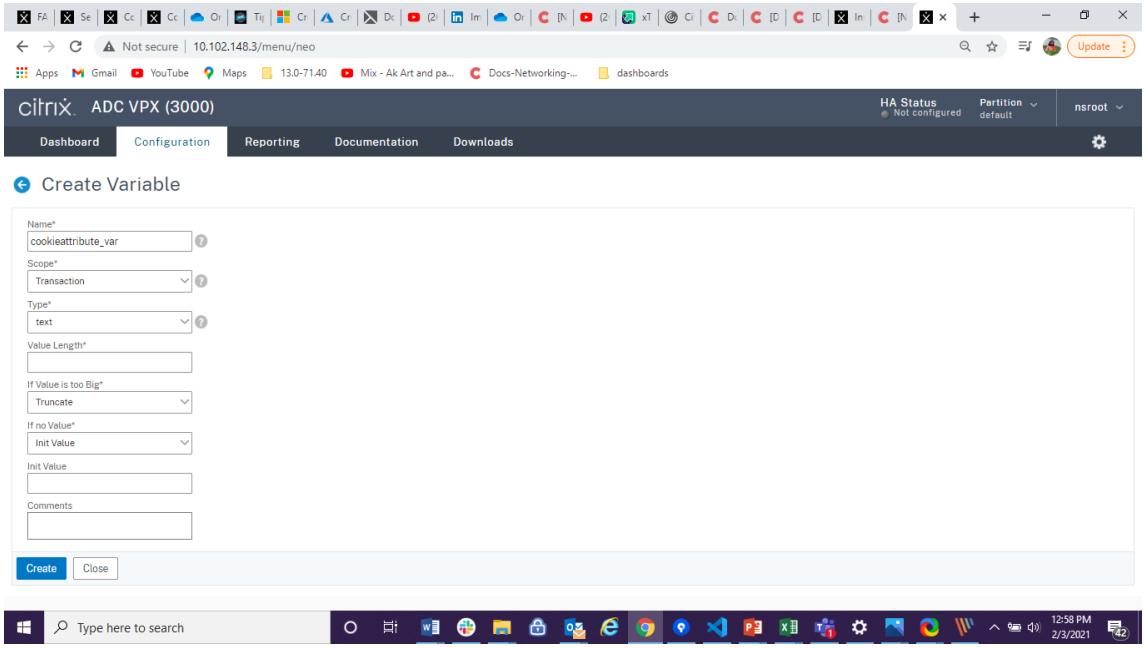
The **Computed ADC Cookie Attribute** setting allows you to conditionally insert the cookie attributes, based on the client or server attributes, to the ADC generated cookie.

At the command prompt, type:

```
set lb parameter -ComputedADCCookieAttribute <ns variable>
```

Example:

```
add ns variable cookieattribute_var -type "text(100)" -scope
    transaction
set lb parameter -ComputedADCCookieAttributE "$cookieattribute_var"
add ns assignment samesiteassign -variable "$cookieattribute_var" -set
    "\"SameSite=None\""



add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
    /OS \\d+\\_/).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).EQ(12).
    typecast_text_t ALT \"false\").eq(\"true\"))"
add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
    (re/Chrom.*\\d+./).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).
    BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
add rewrite policy exception_samesite_attribute "pol_iphone ||
    pol_chrome " NOREWRITE
add rewrite policy append_samesite_attribute true samesiteassign

bind rewrite global exception_samesite_attribute 90 110 -type
    RES_OVERRIDE
bind rewrite global append_samesite_attribute 100 110 -type
    RES_OVERRIDE
```

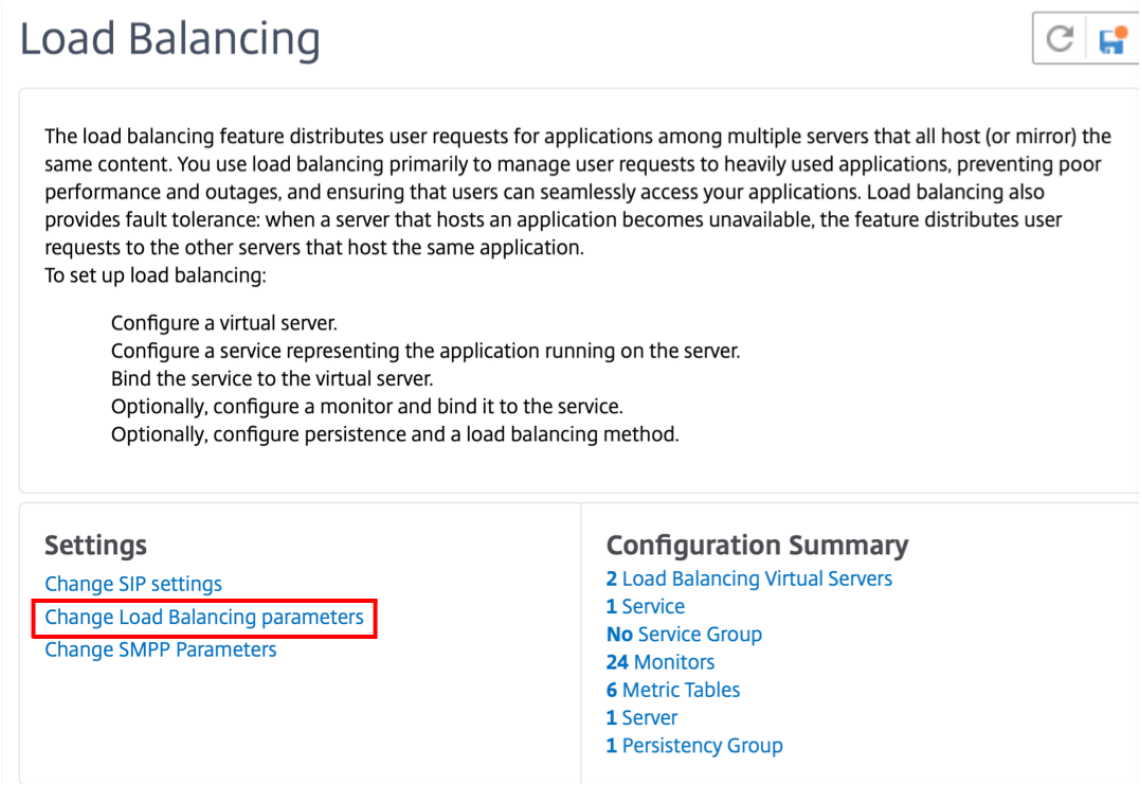
Configure variables by using the GUI

1. Navigate to **AppExpert > Variables**, and click **Add**.
2. In the **Create Variable** page, select **Scope** as **Transaction** and **Type** as **text** from the drop-down menu.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. Enter other details, and click **Create**.

Create an assignment by using the GUI

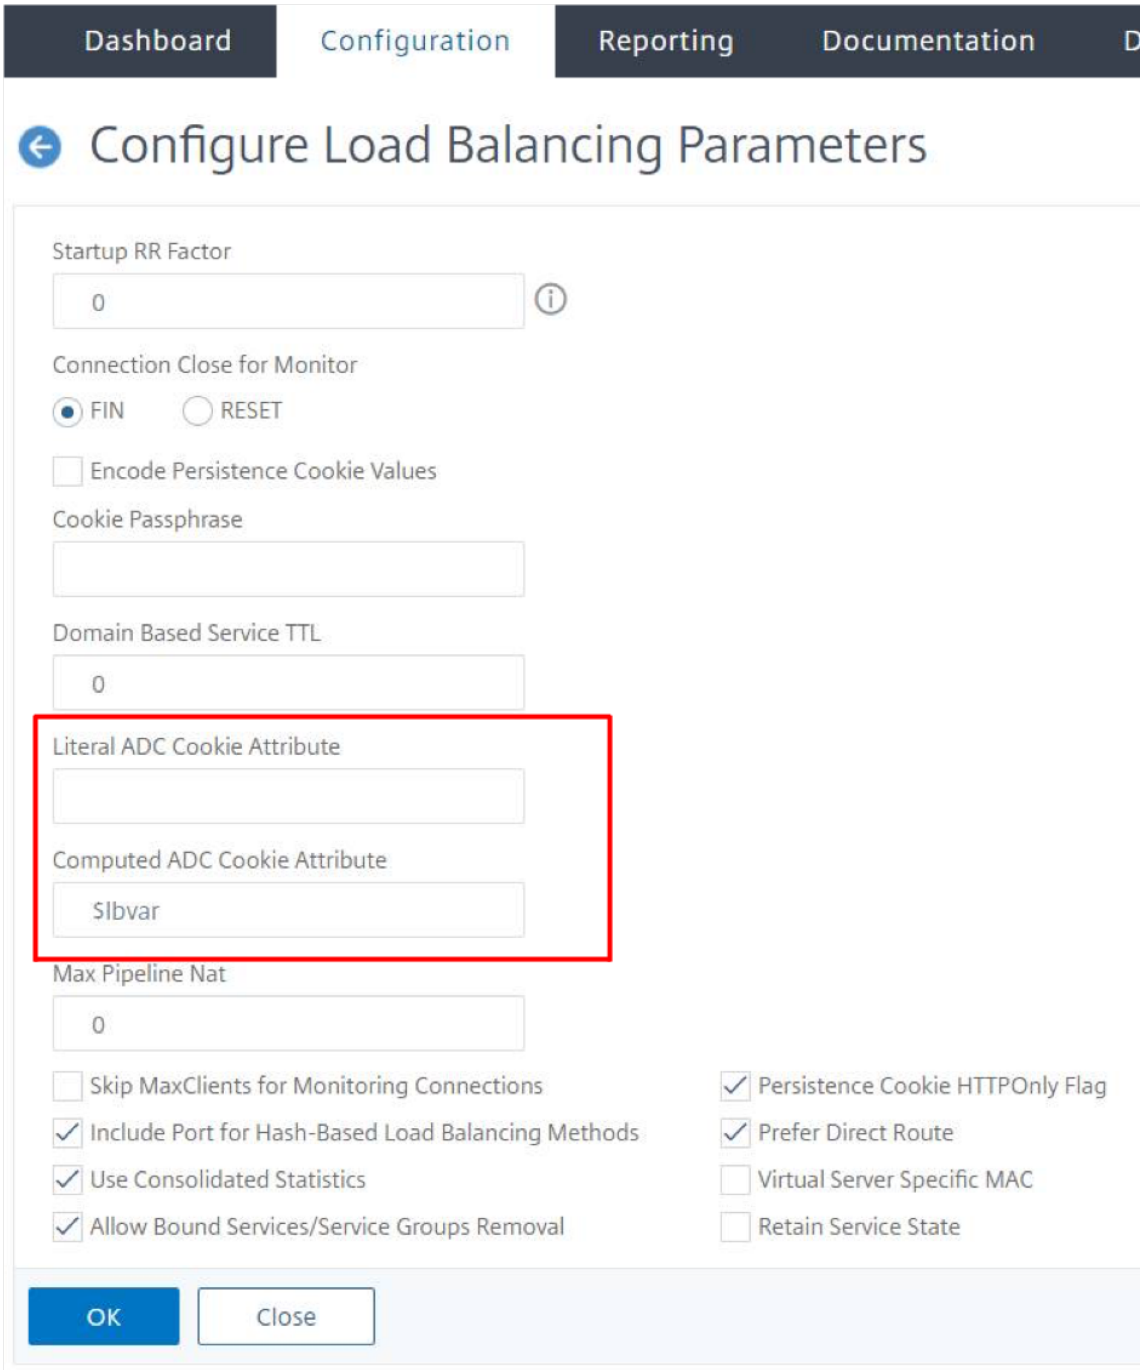


After configuring a variable, you can assign a value or specify the operation to be performed on the variable by creating an assignment.

1. Navigate to **AppExpert > Assignments**, and click **Add**.
2. In the **Create Assignment** page, enter the details, and click **Create**.

Setting the ADC cookie attributes in load balancing parameters by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing parameters**.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. In the **Configure Load Balancing Parameters** pane, enter appropriate values for either one of the fields based on your requirement:

   - **Literal ADC Cookie Attribute**
   - **Computed ADC Cookie Attribute**

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. Click **OK**.

Setting the ADC cookie attributes in the load balancing profile by using the CLI

To apply a policy for a specific application that is configured on the Citrix ADC appliance, you can set the cookie attribute parameters in the LB profile bound to the application-specific LB virtual server.

The **Literal ADC Cookie Attribute** setting in the LB profile allows you to unconditionally insert the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

cookie attributes to the ADC generated cookie that is specific to a virtual server.

At the command prompt, type:

```
add lb profile <profile name> -LiteralADCCookieAttribute <string>
```

Example:

```
add lb profile LB-Vserver-Profile-1 -LiteralADCCookieAttribute SameSite
    =None
add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
    COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
```

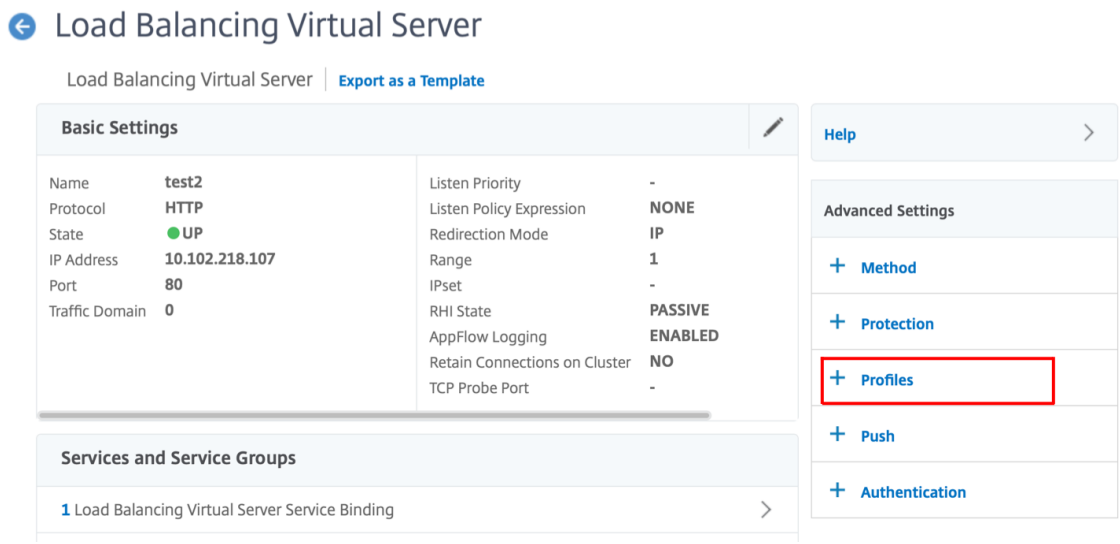
The **Computed ADC Cookie Attribute** setting in the LB profile allows you to conditionally insert the cookie attributes based on the client or server attributes, to the ADC generated cookie. Then, set this LB profile to an LB virtual server.

At the command prompt, type:

```
add lb profile <profile name> -ComputedADCCookieAttribute <ns variable>
```

Example:

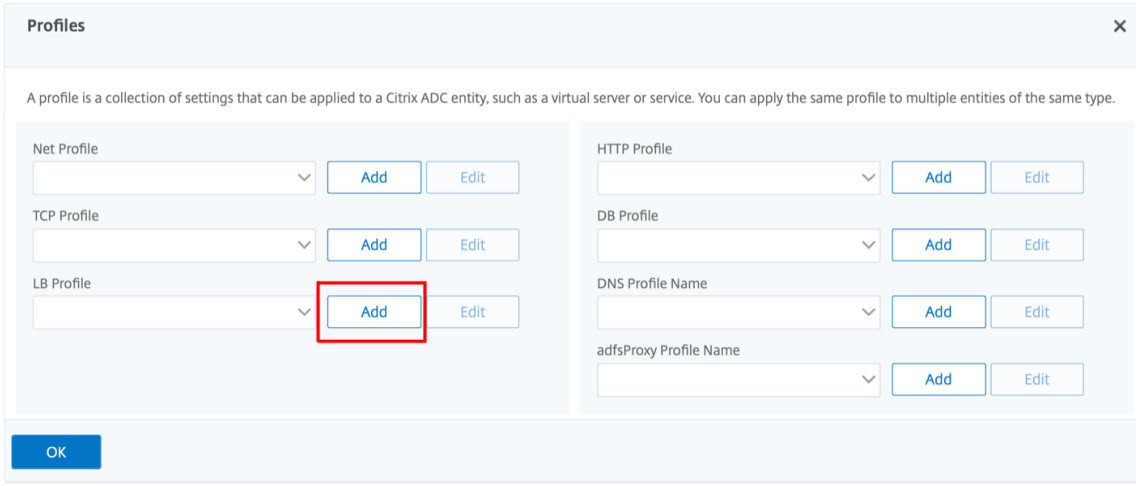
```
add ns variable cookieattribute_var -type "text(100)" -scope
    transaction
add ns assignment samesiteassign -variable "$cookieattribute_var" -set
    "\"SameSite=None\""
add lb profile LB-Vserver-Profile-1 -ComputedADCCookieAttributE "
    $cookieattribute_var"



add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
    /OS \\d+\\_/).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).EQ(12).
    typecast_text_t ALT \"false\").eq(\"true\"))"
add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
    (re/Chrom.*\\d+./).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).
    BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
add rewrite policy exception_samesite_attribute "pol_iphone ||
    pol_chrome " NOREWRITE
add rewrite policy append_samesite_attribute true samesiteassign

add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
    COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
bind lb vserver LB-VServer-1 -policyName exception_samesite_attribute -
    priority 90 -gotoPriorityExpression 110 -type RESPONSE
bind lb vserver LB-VServer-1 -policyName append_samesite_attribute -
    priority 100 -gotoPriorityExpression 110 -type RESPONSE
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



Setting the ADC Cookie attributes in the load balancing profile by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual servers**.
2. Select a virtual server and click **Edit**.
3. Under **Advanced Settings** section, click **Add profiles**.

4. In the **Profiles** section, click **Add** to create an LB Profile.

   If you have already created a profile, choose it from the **LB Profile** drop-down menu.

5. In the **LB Profile** pane, enter appropriate values for either one of the fields based on your requirement:

- **Literal ADC Cookie Attribute**
- **Computed ADC Cookie Attribute**

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Click **OK**.
2. Set the created LB profile to the LB virtual server created in **Step 1**.

Verify ns variable configuration

To verify that the ADC ns variable is configured appropriately in LB parameters or LB profile, use the show lb parameter or show lb profile commands.

The following table lists the various warning messages and its cause, when the ns variable is not correctly configured.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Warning message	Reasons
NS Variable is not configured. Configure it with type text() and scope transaction for variable	NS variable is not yet configured.
Scope of configured NS variable is not transaction.	Variable is configured but scope is not set to "transaction."
Type of variable is not Text().	Variable is configured but type is not set to "Text".
Configured value-max-size for the NS Variable is greater than 255.	The value configured for the NS variable is greater than 255 characters. **Note:** A maximum length of 255 characters can be appended to an ADC generated cookie. The characters that exceed the maximum length are truncated.

Sample output

In the following example, the warning message is displayed when the ns variable is not configured.

```
set lb parameter -ComputedADCCookieAttribute "$lbvar"

Warning: NS Variable is not configured. Please configure it with type
    text() and scope transaction
Done
```

The warning message is displayed in the following output of the `show lb parameter` command.

```
show lb parameter

Global LB parameters:
Persistence Cookie HttpOnly Flag: ENABLED
Use Encrypted Persistence Cookie: DISABLED
Use Port For Hash LB: YES
Prefer direct route: YES
Retain Service State: OFF
Start RR Factor: 0
Skip Maxclient for Monitoring: DISABLED
Monitor Connection Close: FIN
Use consolidated stats for LeastConnection: YES
Allow mac mode based vserver to pick thereturn traffic from services:
    DISABLED
Allow bound service removal: ENABLED
TTL for Domain Based Server: 0 secs

Citrix ADC Cookie Variable Name: $lbvar(NS Variable is not configured.
    Please configure it with type text() and scope transaction)

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
19 Done
```

Sample configuration for inserting cookie attributes in GSLB deployment

The following sample configuration applies to site persistence configured on GSLB services corresponding to an LB virtual server. To append some additional cookie attributes to the GSLB cookies, perform the following configuration.

- Set the ADC cookie attributes in the LB profile (LB-Vserver-Profile-1).
- Set the Literal ADC Cookie Attribute value, for example "SameSite=None", in the LB profile.
- Set the LB profile to the load balancing virtual server (LB-VServer-1), which represents the GSLB service.

```
1  add gslb vserver GSLB-VServer-1 SSL -backupLBMethod ROUNDROBIN -
       tolerance 0 -appflowLog DISABLED
2  add gslb site site1 10.102.148.4 -publicIP 10.102.148.4
3  add gslb service site1_gsvc1 10.102.148.35 SSL 443 -publicIP
       10.102.148.35 -publicPort 443 -maxClient 0 -siteName site1 -
       sitePersistence HTTPRedirect -sitePrefix ss1 -cltTimeout 180 -
       svrTimeout 360 -downStateFlush ENABLED
4
5  bind gslb vserver GSLB-VServer-1 -serviceName site1_gsvc1
6  bind gslb vserver GSLB-VServer-1 -domainName www.gslb.com -TTL 5
7
8  add service service-1 10.102.84.140 SSL 443
9
10 add lb profile LB-Vserver-Profile-1 -LiteralADCCookieAttribute SameSite
       =None
11 add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
       COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
12
13 bind lb vserver LB-VServer-1 service-1
```

> **Note**
>
> You can also conditionally insert the cookie attributes using the Computed ADC Cookie Attribute.

Sample configuration for inserting cookie attribute in content switching deployment

The following sample configuration applies when multiple applications are hosted behind a content switching virtual server. To apply the same policy to all the applications, bind the rewrite policies to content switching virtual server instead of LB virtual server, as follows:

- Set the ADC cookie attributes in the LB parameters.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:**
>
> You can set the ADC cookie attributes in the LB profile as well.

- Configure the ns variable (cookieattribute_var) of Type set to Text and Scope set to Transaction.
- Set the Computed ADC Cookie Attribute in the global LB parameters using the ns variable.
- Set the rewrite policies (exception_samesite_attribute and append_samesite_attribute) to the content switching virtual servers for inserting the cookie attributes.

```
add ns variable cookieattribute_var -type "text(100)" -scope
    transaction
set lb parameter -ComputedADCCookieAttributE "$cookieattribute_var"
add ns assignment samesiteassign -variable "$cookieattribute_var" -set
    "\"SameSite=None\""

add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
    /OS \\d+\\_/).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).EQ(12).
    typecast_text_t ALT \"false\").eq(\"true\"))"
add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
    CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
    (re/Chrom.*\\d+./).REGEX_SELECT(re/\\d+/).TYPECAST_NUM_T(DECIMAL).
    BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
add rewrite policy exception_samesite_attribute "pol_iphone ||
    pol_chrome " NOREWRITE
add rewrite policy append_samesite_attribute true samesiteassign

add lb vserver LB-VServer-1 SSL 10.102.148.35 443
add lb vserver LB-VServer-2 SSL 10.102.148.36 443

add cs vserver CS-VServer-1 SSL 10.102.148.42 443 -persistenceType
    COOKIEINSERT

add cs action act1 -targetLBVserver v1
add cs action act2 -targetLBVserver v2
add cs policy CS-policy-1 -rule "HTTP.REQ.URL.CONTAINS(\"file1.html\")"
     -action act1
add cs policy CS-policy-2 -rule "HTTP.REQ.URL.CONTAINS(\"file2.html\")"
     -action act2

bind cs vserver CS-VServer-1 -policyName CS-policy-1 -priority 1
bind cs vserver CS-VServer-1 -policyName CS-policy-2 -priority 2

bind cs vserver -policyname exception_samesite_attribute 90 110 -type
    RES_OVERRIDE
bind cs vserver -policyname append_samesite_attribute 100 110 -type
    RES_OVERRIDE
```

Customize a load balancing configuration

September 14, 2021

After you configure a basic load balancing setup, you can make several modifications to it so that it distributes the load exactly as you need. The load balancing feature is complex. You can modify the basic elements by doing one or more of the following:

- Changing the load balancing algorithm
- Configuring load balancing groups and using them to create your load balancing configuration
- Configuring persistent client-server connections
- Configuring the redirection mode
- Assigning different weights to different services that have different capacities.

The default load balancing algorithm on the Citrix ADC appliance is the least connection method. In the least connection method, the appliance sends each incoming connection to the service that is currently handling the fewest connections. You can specify different load balancing algorithms, each of which is suited to different conditions.

To accommodate applications such as shopping carts, which require that all requests from the same user be directed to the same server, you can configure the appliance to maintain persistent connections between clients and servers. You can also specify persistence for a group of virtual servers. Persistence lets the appliance to direct individual client requests to the same service regardless of which virtual server in the group receives the client request.

You can enable and configure the redirection mode that the appliance uses when redirecting user requests, choosing between IP-based and MAC-based forwarding. You can also assign weights to different services, specifying what percentage of incoming load must be directed to each service. Assigning weights enable you to include servers with different capacities in the same load balancing setup without;

- overloading the lower-capacity servers or
- allowing the higher-capacity servers to sit idle.

Customize the hash algorithm for persistence across virtual servers

September 14, 2021

The Citrix ADC appliance uses hash-based algorithms for maintaining persistence across virtual servers. By default, the hash-based load balancing method uses a hash value of the IP address and

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

port number of the service. If a service is made available at different ports on the same server, the algorithm generates different hash values. Therefore, different load balancing virtual servers might send requests for the same application to different services, breaking the pseudo-persistence.

As an alternative to using the port number to generate the hash value, you can specify a unique hash identifier for each service. For a service, the same hash identifier value must be specified on all the virtual servers. If a physical server serves more than one type of application, each application type should have a unique hash identifier.

The algorithm for computing the hash value for a service works as follows:

- By default, a global setting specifies the use of port number in a hash calculation.
- If you configure a hash identifier for a service, it is used, and the port number is not, regardless of the global setting.
- If you do not configure a hash identifier, but change the default value of the global setting so that it does not specify use of the port number, the hash value is based only on the IP address of the service.
- If you do not configure a hash identifier or change the default value of the global setting to use the port number, the hash value is based on the IP address and the port number of the service.

You can also specify hash identifiers when using the CLI to bind services to a service group. In the configuration utility, you can open a service group and add hash identifiers on the Members tab.

To change the use-port-number global setting by using the CLI

At the command prompt, type:

set lb parameter -usePortForHashLb (YES NO)

Example:

```
1 > set lb parameter -usePortForHashLb NO
2  Done
3 >show lb parameter
4 Global LB parameters:
5         Persistence Cookie HttpOnly Flag: DISABLED
6         Use port for hash LB: NO
7  Done
```

To change the use-port-number global setting by using the GUI

1. Navigate to Traffic Managment > Load Balancing > Configure Load Balancing parameters.
2. Select or clear Use Port for Hash Based LB Methods.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To create a new service and specify a hash identifier for a service by using the CLI

At the command prompt, type the following commands to set the hash ID and verify the setting:

add service < name > (< ip >	< serverName >) < serviceType > < port > -hashId < positive_integer >

```
show service <name>
```

Example:

```
> add service flbkng 10.101.10.1 http 80 -hashId 12345
 Done
>show service flbkng
        flbkng (10.101.10.1:80) - HTTP
        State: DOWN
        Last state change was at Thu Nov  4 10:14:52 2010
        Time since last state change: 0 days, 00:00:15.990
        Server Name: 10.101.10.1
        Server ID : 0   Monitor Threshold : 0

        Down state flush: ENABLED
        Hash Id: 12345

1)      Monitor Name: tcp-default
                State: DOWN     Weight: 1

 Done
```

To specify a hash identifier for an existing service by using the CLI

Type the set service command, the name of the service, and **-hashID** followed by the ID value.

To specify a hash identifier while adding a service group member

To specify a hash identifier for each member to be added to the group and verify the setting, at the command prompt, type the following commands (Be sure to specify a unique hashID for each member.):

```
bind servicegroup <serviceGroupName> <memberName> <port> -hashId <
   positive_integer>

show servicegroup <serviceGroupName>
```

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
 bind servicegroup http_svc_group 10.102.27.153 80 -hashId 2222222

>show servicegroup SRV
        SRV - HTTP
        State: ENABLED  Monitor Threshold : 0
        ...

        1)         1.1.1.1:80   State: DOWN     Server Name: 1.1.1.1
              Server ID: 123  Weight: 1
        Hash Id: 32211

                Monitor Name: tcp-default       State: DOWN
        ...

        2)         2.2.2.2:80   State: DOWN     Server Name: 2.2.2.2
              Server ID: 123  Weight: 1
        Hash Id: 12345

                Monitor Name: tcp-default       State: DOWN
        ...
Done
```

To specify a hash identifier for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a new service, or open an existing service and specify the hash ID.

To specify a hash identifier for an already configured service group member by using the GUI

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a member and type a unique hash ID.

Configure the redirection mode

September 30, 2021

The redirection mode configures the method used by a virtual server to determine where to forward incoming traffic. The Citrix ADC appliance supports the following redirection modes. Before forwarding the request to a server, the redirection modes function as follows:

- IP-Based forwarding (the default): The destination IP address is changed to the server's IP address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- MAC-Based forwarding: The destination MAC address is changed to the server's MAC address. However, the destination IP address is not changed. MAC-based redirection mode is used mostly in firewall load balancing deployments.
- IP TUNNEL Based: An IP-in-IP encapsulation is performed for the client IP packets. In the outer IP headers, the destination IP address is set to the IP address of the server and the source IP address is set to the subnet IP (SNIP). The client IP packets are not modified. This is applicable to both IPv4 and IPv6 packets.
- TOS ID Based: The virtual server's TOS ID is encoded in the TOS field of the IP header.

You can use either the IP TUNNEL or the TOS option to implement Direct Server Return (DSR). For more information see:

- Configure DSR mode when using TOS
- Configure load balancing in DSR mode for IPv6 networks by using the TOS field
- Configure load balancing in DSR mode by using IP Over IP

You can configure MAC-Based forwarding on networks that use DSR topology, link load balancing, or firewall load balancing. For more information on MAC-Based forwarding for load balancing, see Configure MBF for load balancing configuration.

To configure the redirection mode by using the CLI

At the command prompt, type:

```
set lb vserver <name> -m <RedirectionMode>
```

Example:

```
set lb vserver Vserver-LB-1 -m MAC
```

> **Note**
>
> For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

To configure the redirection mode by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and select the redirection mode.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure per-VLAN wildcarded virtual servers

September 14, 2021

If you want to configure load balancing for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcarded virtual server that listens to a specific VLAN by using the CLI

At the command prompt, type the following commands to configure a wildcarded virtual server that listens to a specific VLAN and verify the configuration:

```
add lb vserver <name> <serviceType> IPAddress * Port * -listenpolicy <
    expression> [-listenpriority <positive_integer>]

show vserver
```

Example:

```
add lb vserver Vserver-LB-vlan1 ANY -listenpolicy "CLIENT.VLAN.ID.EQ(2)
    " -listenpriority 10

show vserver Vserver-LB-vlan1
```

To configure a wildcarded virtual server that listens to a specific VLAN by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Create a new virtual server or open an existing virtual server.
3. Specify a listen policy priority and expression.

After you have created this virtual server, you bind it to one or more services as described in Setting Up Basic Load Balancing.

Assign weights to services

January 16, 2024

In a load balancing configuration, you assign weights to services to indicate the percentage of traffic that should be sent to each service. Services with higher weights can handle more requests; services with lower weights can handle fewer requests. Assigning weights to services allows the Citrix ADC

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

appliance to determine how much traffic each load balanced server can handle, and therefore more effectively balance load.

Note: If you use a load balancing method that supports weighting of services (for example, the round robin method), you can assign a weight to the service.

The following table describes the load balancing methods that support weighting, and briefly describes the manner in which weighting affects how a service is selected for each one.

Load Balancing Methods	Service Selection with Weights
Round Robin	The virtual server prioritizes the queue of available services such that services with the highest weights come to the front of the queue more frequently than those with the lowest weights and receive proportionately more traffic. For a complete description, see The Round Robin Method.
Least Connection	The virtual server selects the service with the best combination of fewest active transactions and highest weight. For a complete description, see The Least Connection Method.
Least Response Time and Least Response Time Method using Monitors	The virtual server selects the service with the best combination of fewest active transactions and fastest average response time. For a complete description, see The Least Response Time Method.
Least Bandwidth	The virtual server selects the service with the best combination of least traffic and highest bandwidth. For a complete description, see The Least Bandwidth Method.
Least Packets	The virtual server selects the service with the best combination of fewest packets and highest weight. For a complete description, see The Least Packets Method.
Custom Load	The virtual server selects the service with the best combination of lowest load and highest weight. For a complete description, see The Custom Load Method.
Hashing methods, Static proximity and Token method	Weighting is not supported by these load balancing methods.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Load Balancing Methods	Service Selection with Weights
Least Request	The virtual server selects the service with the combination of fewest active requests and highest weight. For a complete description, see The Least Request Method.

To configure a virtual server to assign weights to services by using the CLI

At the command prompt, type:

```
set lb vserver <name> -weight <Value> <ServiceName>
```

Example:

```
set lb vserver Vserver-LB-1 -weight 10 Service-HTTP-1
```

To configure a virtual server to assign weights to services by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Open the virtual server, and then click in the **Services** section.
3. In the weight column for the service, assign a weight to the service.

Configure the MySQL and Microsoft SQL server version setting

September 14, 2021

You can specify the version of Microsoft® SQL Server® and the MySQL server for a load balancing virtual server that is of type MSSQL and MySQL respectively. The version setting is recommended if you expect some clients to not be running the same version as your MySQL or Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

To set the Microsoft SQL server version parameter by using the CLI

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a load balancing virtual server and verify the configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set lb vserver <name> -mssqlServerVersion <mssqlServerVersion>

show lb vserver <name>
```

Example

```
> set lb vserver myMSSQLvip -mssqlServerVersion 2008R2
 Done
> show lb vserver myMSSQLvip
    myMSSQLvip (190.0.2.12:1433) - MSSQL    Type: ADDRESS
 . . .
 . . .
    MSsql Server Version: 2008R2
    . . .
    . . .
 Done
>
```

To set the MySQL server version parameter by using the CLI

At the command prompt, type the following commands to set the MySQL Server version parameter for a load balancing virtual server and verify the configuration:

```
set lb vserver <name> -mysqlServerVersion <string>

show lb vserver <name>
```

Example

```
> set lb vserver mysqlsvr -mysqlserverversion 5.5.30
 Done
> sh lb vserver mysqlsvr
     mysqlsvr (2.22.2.222:3306) - MYSQL      Type: ADDRESS
 . . .
 . . .
     Mysql Server Version: 5.5.30
    . . .
    . . .
 Done
>
```

To set the MySQL or Microsoft SQL server version parameter by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. Open a virtual server of type MySQL or MSSQL, and set the server version.

Multi-IP virtual servers

May 19, 2022

The Citrix ADC supports creating a single load balancing virtual server with multiple non-consecutive/consecutive IPv4 and IPv6 addresses of type VIP. Each VIP address bound to a virtual server is treated as an individual virtual server. These virtual servers have the same protocol and other virtual server level settings. A virtual server with multiple VIP addresses is also called multi-IP virtual server.

The following are some advantages of using multi-IP virtual servers:

- A multi-IP virtual server offloads the work of creating many virtual servers with the same settings and service bindings.
- Multi-IP virtual servers effectively reduces the possibility of reaching the maximum limit on virtual server entities.
- One multi-IP virtual server can be used for clients in different subnets to connect to the same set of servers.
- Only one multi-IP virtual server can be used for IPv6 and IPv4 clients to connect to the same set of servers.

Configure a multi-IP virtual server

Configuring a multi-IP virtual server consists of the following tasks:

- Create an IPset and bind multiple IP addresses to it.
- Bind the IPset to load balancing virtual servers.

Note the following points related to IPset configuration:

- An IPset can have:
  - non-consecutive/consecutive IPv4 addresses and IPv6 addresses
  - combinations of IPv4 and IPv6 addresses.
- All IPv4/IPv6 addresses to be associated with virtual servers using IPset must be of type VIP.
- A single IPset can be bound to multiple virtual servers.
- IPv4/IPv6 addresses can be bound/unbound to/from IPset irrespective any existing IPset bindings to virtual servers.
- You must unset the IPset binding to a virtual server before binding a new IPset to it.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To add an IPset and bind multiple VIP addresses to it by using the CLI

At the command prompt, type:

```
add ipset <name>

bind ipset <name> <IPaddress1 ...>

bind ipset <name> <IPaddress2...>

show ipset <name>
```

To bind the IPset to a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -ipset <ipset name>

show lb vserver <name>
```

To add an IPset and bind multiple VIP addresses to it by using the GUI

Navigate to **System** > **Network** > **IPSets**, and create an IPset with multiple VIP addresses.

To bind the IPSet to a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server to which you want to bind the created IPset.
2. In **Basic Settings**, set the **IPset** parameter to the name of the created IPset.

```
> add ipset IPSET-1

Done

> bind ipset IPSET-1 9.9.9.10

Done

> bind ipset IPSET-1 1000::20

Done

> add lb vserver LBVS-1 HTTP 8.8.8.10 80  – ipset IPSET-1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
17
18
19 Done

21 > add service SVC-1 3.3.3.10 HTTP 80
22
23
24 Done
25
26 > add service SVC-2 3.3.3.100 HTTP 80
27
28
29 Done
30
31 > bind lb vserver LBVS-1 SVC-1
32
33
34 Done
35
36 > bind lb vserver LBVS-1 SVC-2
37
38
39 Done
```

GSLB support for multi-IP virtual servers

Floating IP addresses are required for the high availability deployments. Cloud deployments do not support floating IP addresses. So, the IP set feature helps you support high availability in cloud deployments. With the IP set feature, you can associate a private IP address to each of the primary and secondary instances. One of the private IP addresses is added when creating the virtual server. The other IP address is bound to an IP set. The IP set is then associated with the virtual server. Typically a public IP address is mapped to one of the private IP addresses based on which appliance is taking the traffic. During failover, this mapping changes dynamically to route the traffic to the new primary.

In GSLB deployments, the GSLB service represents the virtual server and it requires both the private and public IP address of the virtual server. In cloud deployments, there are multiple private IP addresses represented as an IP set but the GSLB service can accept only one private IP address. So while configuring the GSLB service it is recommended to give the IP address that is configured while adding the virtual server or one of the IP addresses in the IP set. You need not configure the IP set feature on the GSLB service. The IP set configured on the load balancing virtual server associated with the GSLB service is sufficient.

In GSLB Parent-child topology, the load balancing virtual servers on the child sites can have the IP set associated with it. The GSLB service corresponding to this topology carries the public IP address and one of the private IP addresses. The private IP address can be an IP address in the IP set or the one configured while adding the virtual server on the child site. Communication between the parent and

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

the child sites is always using the public IP address and the public port of the GSLB service.

Also, with IP set support, you can have a single virtual server endpoint for both IPv4 and IPv6 traffic. Previously, you had to configure different virtual servers for IPv4 and IPv6 traffic. With IP set support, you can associate IPv4 and IPv6 IP addresses to the same IP set. You can add different GSLB services representing the IPv4 and IPv6 endpoints.

Limit the number of concurrent requests on a client connection

September 14, 2021

You can limit the number of concurrent requests on a single client connection. You can protect the servers from security vulnerabilities by limiting the number of concurrent requests. When the client connection reaches the specified maximum limit, the Citrix ADC appliance drops subsequent requests on the connection until the outstanding request count goes below the limit.

You can configure the maxPipelineNat parameter to limit the number of concurrent requests on a single client connection. This parameter is applicable only to the following service types and when "svrTimeout"is set to zero:

- ANY
- All UDP service types except DNS

The default value of maxPipelineNat parameter is 255. A value of zero (0) applies no limit to the number of concurrent requests. When no limit is set, the Citrix ADC appliance executes all requests.

> **Note**
>
> If you set MaxpipelineNAT to a higher value, then the probability of spoofing attack can be higher. Hence, it is recommended to set MaxpipelineNAT to a lower value.

To limit the number of concurrent connections for a client by using the CLI

At the command prompt, type:

```
set lb parameter -maxPipelineNat <positive_integer>
```

Example:

```
set lb parameter -maxPipelineNat 199
```

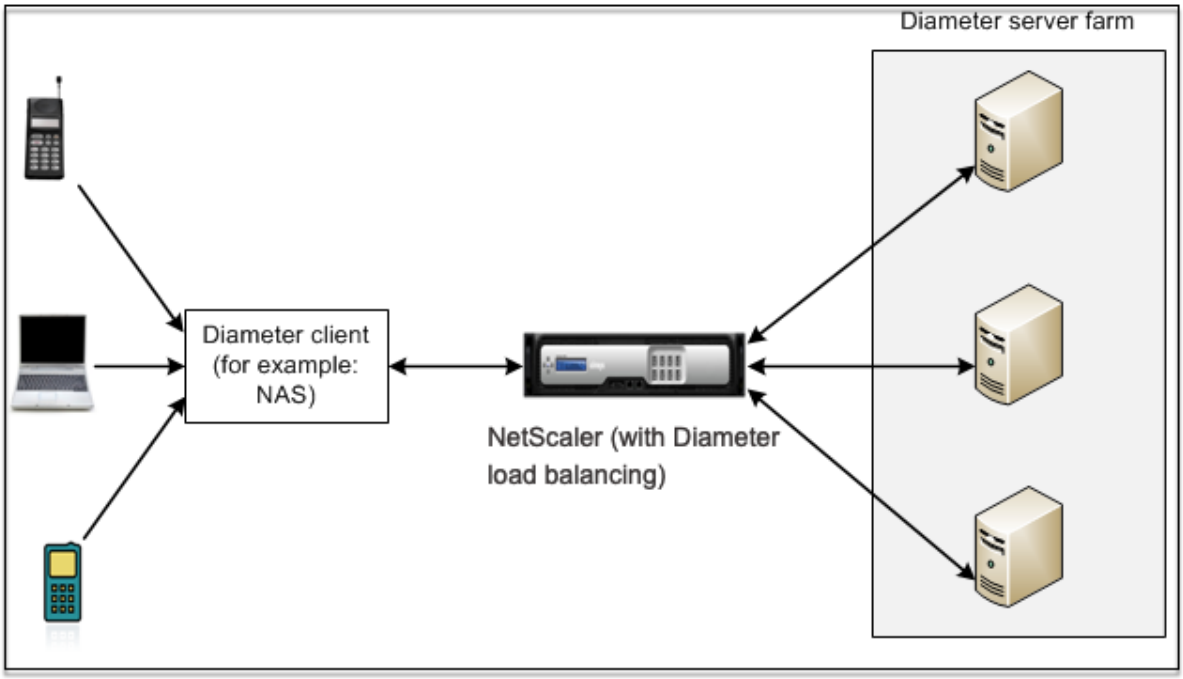
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To limit the number of concurrent connections for a client by using the GUI

Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, specify a value for Max Pipeline NAT requests.

Configure diameter load balancing

September 27, 2023



The Diameter protocol is a next generation Authentication, Authorization, and Accounting (AAA) signaling protocol used mainly on mobile devices such as laptops and mobile phones. It is a peer-to-peer protocol, as opposed to the traditional client-server model used by most other protocols. However, in most Diameter deployments, the clients originates the request and the server responds to the request.

When Diameter messages are exchanged, the Diameter server usually does much more processing than does the Diameter client. With the increase in control plane signaling volume, the Diameter server becomes a bottleneck. Therefore, Diameter messages must be load balanced to multiple servers. A virtual server performing load balancing of Diameter messages provides the following benefits:

- Lighter load on Diameter servers, which translates to faster response time to end users.
- Server health monitoring and better failover capabilities.
- Better scalability in terms of server addition without changing client configuration.
- High availability.
- SSL-Diameter offloading.

The following figure shows a Diameter system in a Citrix ADC deployment:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

A Diameter system has the following components:

- **Diameter client.** Supports Diameter client applications in addition to the base protocol. Diameter clients are often implemented in devices at the edge of a network and provide access control services for that network. Typical examples of Diameter clients are a Network Access Server (NAS) and the Mobile IP Foreign Agent (FA).
- **Diameter agent.** Provides relay, proxy, redirect, or translation services. The Citrix ADC appliance (configured with a Diameter load balancing virtual server) plays the role of a Diameter agent.
- **Diameter server.** Handles the authentication, authorization, and accounting requests for a particular realm. A Diameter server must support Diameter server applications in addition to the base protocol.

In a typical Diameter topology, when an end-user device (such as a mobile phone) needs a service, it sends a request to a Diameter client. Each Diameter client establishes a single connection (TCP connection—SCTP is not yet supported) with a Diameter server as specified by the Diameter base-protocol RFC 6733. The connection is long-lived and all messages between the two Diameter nodes (client and server) are exchanged over this connection. The Citrix ADC uses message based load balancing.

Example:

A mobile service provider uses Diameter for its billing system. When a subscriber uses a prepaid number, the Diameter client repeatedly sends requests to the server to check the available balance. The Diameter protocol establishes a connection between the client and the server, and all requests are exchanged over that connection. Connection based load balancing would be pointless, because there

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

is only one connection. However, with the large number of messages on the connection, message based load balancing expedites the process of billing the prepaid mobile subscriber.

How diameter load balancing works

A Diameter client opens a connection to the NetScaler appliance and sends a Diameter Capability Exchange Request (CER) message. The NetScaler selects a diameter server, opens a connection to the server, and forwards the CER message to the server. The server reads the client identity and determines that it is directly connected to the client.

The Diameter server prepares the Diameter handshake reply and sends it to the NetScaler appliance. The appliance modifies the handshake and inserts its own identity. At this point, the Diameter client determines that it is directly connected to the NetScaler (the agent).

> **Note:**
>
> All Diameter request messages from the client are queued on the selected server until the Diameter handshake is complete. The packets are forwarded to the server when the handshake is complete.

Load balancing diameter traffic

When a client sends a request to the Citrix ADC appliance, the appliance parses the request and contextually load balances it to a Diameter server based on a persist AVP. The appliance has advertised the client identity to the server, so it does not add route entries, because the server is expecting messages directly from client.

Server initiated requests are not as frequent as client requests. Server initiated requests are similar to client initiated requests, except:

- Since messages are received from multiple servers, the appliance maintains the transaction state by adding a unique Hop by Hop (HbyH) number to each forwarded request message. When the message response arrives (with same HbyH number), the appliance translates this HbyH number to the HbyH number that was received on the server when the request arrived.
- The Citrix ADC appliance adds a route entry by putting its identity, because the client sees the appliance as a relay agent.

Note: If a Diameter message spans more than one packet, the appliance accumulates the packets in an incomplete header queue and forwards them to the server when the full message is accumulated. Similarly, if a single packet contains more than one Diameter message, the appliance splits the packet and forwards the messages to servers as determined by the load balancing virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Disconnect a session

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the Citrix ADC appliance receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the appliance ignores them. The client sends a FIN, which the appliance broadcasts to all servers.
- When the appliance receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the appliance replies with FIN/ACK and removes connections from the reuse pool.
- If the appliance receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the appliance receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

Configure load balancing for diameter traffic

To configure the Citrix ADC appliance to load balance diameter traffic, you must first set the Diameter parameters on the appliance, then add the diameter monitor, add the diameter services, bind the services to the monitor, add the diameter load balancing virtual server, and bind the services to the virtual server.

To configure load balancing for diameter traffic by using the command line interface

Configure the diameter parameters.

```
set ns diameter -identity <string> -realm <string> -
    serverClosePropagation <YES|NO>
```

Example:

```
set ns diameter -identity mydomain.org -realm org -
    serverClosePropagation YES
```

Add a Diameter monitor.

```
add lb monitor <monitorName> DIAMETER -originHost <string> -originRealm
     <string>
```

Example:

```
add lb monitor diameter_mon DIAMETER -originHost mydomain.org -
    originRealm org
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Create the Diameter services.

```
add service <name> <IP> DIAMETER <port>
```

Example:

```
add service diameter_svc0 10.102.82.86 DIAMETER 3868

add service diameter_svc1 10.102.82.87 DIAMETER 3868

add service diameter_svc2 10.102.82.88 DIAMETER 3868

add service diameter_svc3 10.102.82.89 DIAMETER 3868
```

Bind the Diameter services to the Diameter monitor.

```
bind service <name>@ monitorName <monitorName>
```

Example:

```
bind service diameter_svc0 -monitorName diameter_mon

bind service diameter_svc1 -monitorName diameter_mon

bind service diameter_svc2 -monitorName diameter_mon

bind service diameter_svc3 -monitorName diameter_mon
```

Add a Diameter load balancing virtual server with Diameter persistence.

```
add lb vserver <name> DIAMETER <IPAddress> <port> -persistenceType
   DIAMETER -persistAVPno <positive_integer>
```

Example:

```
add lb vserver diameter_vs DIAMETER 10.102.112.152 3868 -
   persistenceType DIAMETER -persistAVPno 263
```

Bind the Diameter services to the Diameter load balancing virtual server.

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver diameter_vs diameter_svc0

bind lb vserver diameter_vs diameter_svc1

bind lb vserver diameter_vs diameter_svc2

bind lb vserver diameter_vs diameter_svc3
```

Save the configuration.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
save ns config
```

Note: You can also configure load balancing of Diameter traffic over SSL by using the **SSL_DIAMETER** service type.

To configure load balancing for Diameter traffic by using the configuration utility

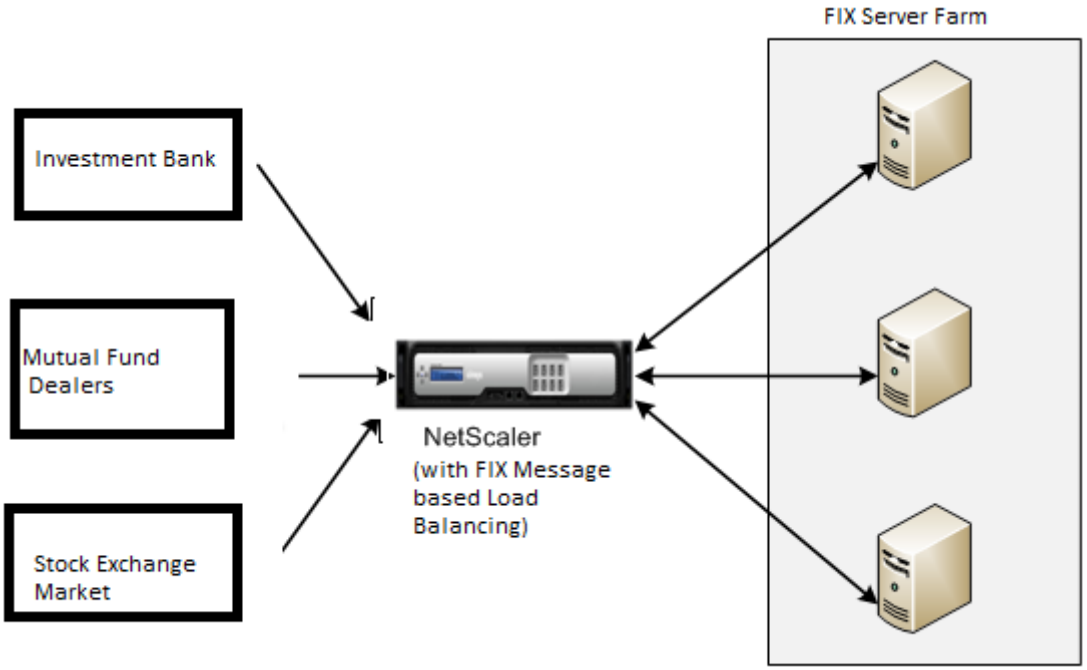
1. Navigate to **System** > **Settings** > **Change Diameter Parameters** and set the diameter parameters.
2. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and create a load balancing virtual server of type Diameter.
3. Create a service of type Diameter.
4. Create a monitor of type Diameter. In Special parameters, set the origin host and origin realm.
5. Bind the monitor to the service, and bind the service to the Diameter virtual server.
6. In Advanced Settings, click **Persistence**, specify the diameter, and enter a persistence AVP number.
7. Click **Save**, and click **Done**.

Configure FIX load balancing

September 14, 2021

Financial Information eXchange (FIX) protocol is an open message standard used in the financial industry for electronic exchange of information related to securities transaction between trading partners. FIX/SSL_FIX protocol is used extensively by buy-side and sell-side firms, trading platforms, and regulators for communicating trade information.

This feature enables you to configure a FIX or SSL_FIX load balancing virtual server to distribute incoming FIX messages and provide security in FIX messaging. Citrix ADC supports FIX message based load balancing (MBLB) for FIX 4.1, FIX 4.2, FIX 4.3, and FIX 4.4 versions.



FIX MBLB on a Citrix ADC appliance provides the following benefits:

1. Efficient management of FIX or SSL_FIX servers with superior HA and health monitoring.
2. SYN protection to all FIX or SSL_FIX servers.
3. FIX session persistence.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

How FIX load balancing works

A FIX MBLB setup includes a FIX load-balancing virtual server and multiple load-balanced FIX servers. The FIX virtual server receives incoming client traffic, parses the incoming traffic into FIX messages, selects a FIX server for each FIX message, and forwards the message to the selected FIX server. The following conceptual drawing illustrates a typical FIX load balancing setup.

In a basic FIX MBLB setup, the FIX virtual server distributes FIX messages coming from clients to the load-balanced FIX servers using the round robin load-balancing method. With persistence of type FIXSESSION enabled, the FIX virtual server selects the same server for different FIX messages belonging to the same FIX session. The FIX session is determined based on the values of the **FIX** fields SenderCompID (tag 49) and TargetCompID (tag 56).

Configure and monitor load balancing for FIX traffic

Following are the configurations that you must do to load balance FIX message traffic:

1. Configuring FIX load balancing virtual server
2. Configuring SSL_FIX load balancing virtual server
3. Configuring FIX load balancing service
4. Configuring SSL_FIX load balancing service
5. Configuring FIXSESSION persistence
6. Setting persistence timeout
7. Displaying FIX/SSL_FIX stats

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

8. Monitoring FIX/SSL_FIX persistent sessions

To configure a FIX load balancing server by using the command line interface

At the command prompt, type:

```
add lb vserver <name> FIX <IP> <PORT>
```

Example

```
add lb vserver vs1 FIX 10.102.82.86 3868
```

To configure a SSL_FIX load balancing virtual server by using the command line interface

At the command prompt, type:

```
add lb vserver <name> SSL_FIX <IP> <PORT>
```

Example

```
add lb vserver vs1 SSL_FIX 10.102.82.86 3868
```

To configure a FIX service by using the command line interface

At the command prompt, type:

```
add service <name> <ip-addr> FIX <port>
```

Example

```
add service_svc1 10.102.82.86 FIX 3868
```

To configure a SSL_FIX service by using the command line interface

At the command prompt, type:

```
add service <name> <ip-addr> SSL_FIX <port>
```

Example

```
add service svc1 10.102.82.86 SSL_FIX 3868
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure FIXSESSION persistence by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -persistenceType FIXSESSION
```

Example

```
set lb vserver vs1 -persistenceType FIXSESSION
```

To set persistence timeout by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -timeout <value>
```

Example

```
set lb vserver vs1 – timeout 2
```

To display FIX stats by using the command line interface

At the command prompt, type:

```
stat lb vserver <name>
```

Example

```
stat lb vserver_svc1
```

To bind FIX service to FIX virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <service name>
```

Example

```
bind lb vserver vs1 svc1
```

To display FIX persistent sessions by using the command line interface

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
show lb persistentSessions <name>
```

Example

```
show lb persistentSessions vs1
```

> **Note**
>
> Note: You can now configure the load balancing of FIX traffic over SSL by using the SSL_FIX service type. This service provides secured communication for FIX messages.

To configure FIX load balancing virtual server by using the GUI

1. Navigate to the **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** page and click **Add** to create a FIX Load Balancing virtual server.
2. On the **Load Balancing Virtual Server** page, set the server parameters:
    a) Virtual Server Name
    b) Protocol type as "FIX"
    c) Server IP Address Type
    d) Server IP Address
    e) Server Port Number
3. Click **OK** and **Continue** to set other parameters.
4. In the **Services** section, select or add a new FIX load balancing virtual service, and bind it to the FIX server.
5. In the **Persistence** section, set the following parameters:
    a) Persistence type as 'FIXSESSION'
    b) Time-out interval
6. Click **OK** and then **Done**.

To edit a FIX load balancing virtual server by using the GUI

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** page, select a FIX server and click **Edit**.

To delete a FIX load balancing virtual server by using the GUI

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** page, select a FIX server, and click **Delete**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure FIX Load Balancing Virtual Service by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** page and click **Add** to create a FIX Load Balancing virtual service.
2. On the **Services** page, set the following parameters. You can click the 'More' arrow to set other parameters such as Traffic Domain, Hash ID, Server ID, Cache Type, and Number of Active Connections.

    a) Service Name –FIX Virtual Service Name
    b) Choose Virtual Server type as (New or Existing)
    c) Protocol –Protocol Type as 'FIX'
    d) Server –Virtual Server IP address
    e) Port –Server Port Number

3. Click **OK** and **Continue** to set other parameters such as Monitors, Threshold & Timeout, Profiles, and Policies.
4. Click **OK** and then **Done**.

To edit a FIX load balancing virtual service by using the GUI

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** page, select a **FIX service** and click **Edit**.

To delete a FIX load balancing virtual service by using the GUI

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** page, select a FIX service, and click **Delete**.

To display FIX load balancing server statistics

Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** page and then click **Statistics** to display the FIX server statistics.

To display Persistent sessions for a FIX server by using the GUI

Navigate to **Configuration** > **Traffic Management** page and, under **Monitor Sessions** click **Virtual Server Persistent Sessions**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

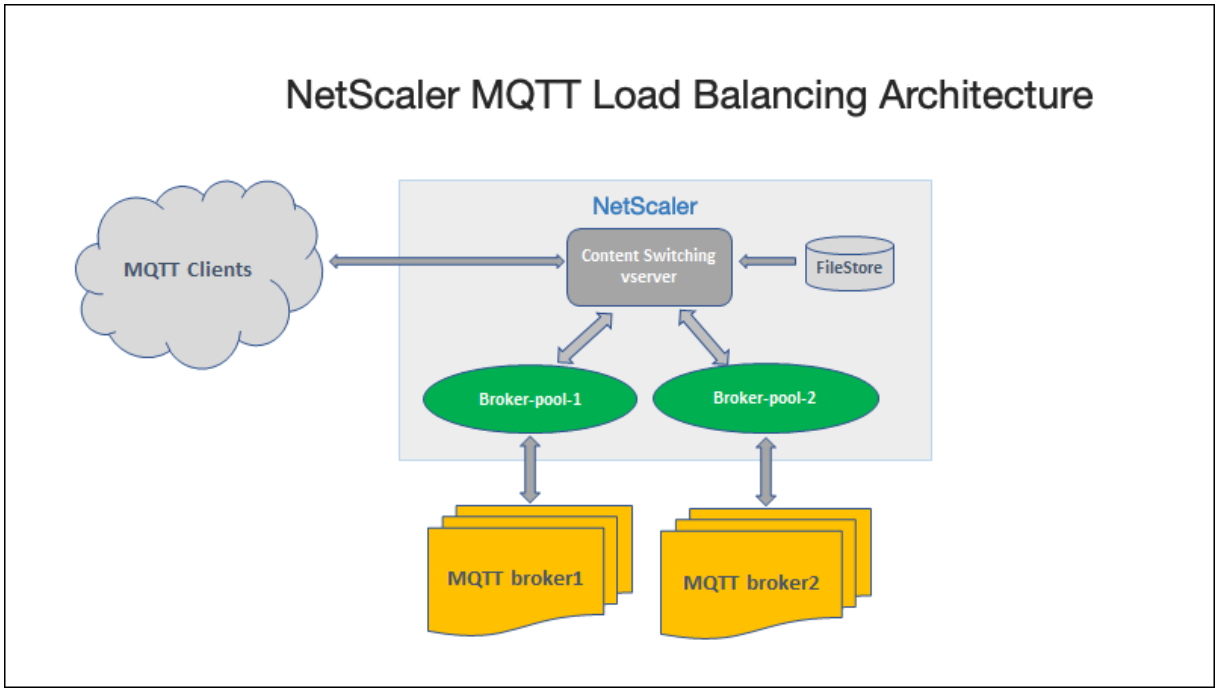
To clear Persistent sessions for a FIX server by using the GUI

1. Navigate to **Configuration** > **Traffic Management** page and, under **Monitor Sessions** click **Clear Persistent Sessions**.
2. On the **Clear Persistent Sessions** page, set the following parameters:
   a) Virtual Server –Choose a FIX virtual server
   b) Persistence Parameter –Choose a FIX persistence parameter
3. Click **OK**.

MQTT load balancing

September 14, 2021

The Message Queuing Telemetry Transport (MQTT) is an OASIS standard messaging protocol for the Internet of Things (IoT). MQTT is a flexible and easy-to-use technology that provides effective communication within an IoT system. MQTT is a broker-based protocol and is widely used to facilitate the exchange of messages between clients and broker.



The following key benefits of MQTT make it a well-suited option for your IoT device:

- Reliability
- Fast response time
- Capability to support unlimited devices
- Publish/subscribe messaging that is perfect for many-to-many communication

IoT is the network of interconnected devices that are embedded with sensors, software, network connectivity, and necessary electronics. The embedded components enable IoT devices to collect and exchange data. The increase in use of IoT devices brings in multiple challenges for network infrastructure, with Scale being the prominent one. In a large scale deployment of IoT devices, the data generated by each IoT device needs to be analyzed swiftly. To achieve the scale requirement and efficient usage of resources, the load on the broker pool must be distributed evenly. With the support of the MQTT protocol, you can use the Citrix ADC appliance in IoT deployments to load balance the MQTT traffic.

The following figure depicts the MQTT architecture using a Citrix ADC appliance to load balance the MQTT traffic.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

An IoT deployment with MQTT protocol has the following components:

- **MQTT broker.** A server that receives all messages from the clients and then routes the messages to the appropriate destination clients. The broker is responsible for receiving all messages, filtering the messages, determining who is subscribed to each message, and sending the message to these subscribed clients. The broker is the central hub through which every message must pass.
- **MQTT client.** Any device, from a micro controller up to a full-fledged server, which runs an MQTT library and connects to an MQTT broker over a network. Both publishers and subscribers are MQTT clients. The publisher and subscriber labels refer to whether the client is publishing messages or subscribed to receive messages.
- **MQTT load balancer.** The Citrix ADC appliance is configured with an MQTT load balancing virtual server to load balance MQTT traffic.

In a typical IoT deployment, the broker (cluster of servers) manages the group of IoT devices (IoT clients). The Citrix ADC appliance load balances the MQTT traffic to the brokers based on various parameters, such as Client ID, topic, and user name.

Configure load balancing for MQTT traffic

For the Citrix ADC appliance to load balance MQTT traffic, perform the following configuration tasks:

1. Configure MQTT/MQTT_TLS services or service groups.
2. Configure MQTT/MQTT_TLS load balancing virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. Bind the MQTT/MQTT_TLS services to the MQTT/MQTT_TLS load balancing virtual server.
4. Configure MQTT/MQTT_TLS content switching virtual server.
5. Configure a content switching action that specifies the target load balancing virtual server
6. Configure a content switching policy.
7. Bind the content switching policy to a content switching virtual server that is already configured to redirect to the specific load balancing virtual server.
8. Save the configuration.

To configure load balancing for MQTT traffic by using the CLI

Configure MQTT/MQTT_TLS services or service groups.

```
add service <name> <IP> <protocol> <port>
add servicegroup <ServiceGroupName> <Protocol>
bind servicegroup <serviceGroupName> <IP> <port>
```

Example:

```
add service srvc1 10.106.163.3 MQTT 1883
add servicegroup srvcg1 MQTT
bind servicegroup srvcg1 10.106.163.3 1883
```

Configure MQTT/MQTT_TLS load balancing virtual server.

```
add lb vserver <name> <protocol> <IPAddress> <port>
```

Example:

```
add lb vserver lb1 MQTT 10.106.163.9 1883
```

Bind the MQTT/MQTT_TLS services or service groups to the MQTT load balancing virtual server.

```
bind lb vserver <name> <serviceName>
bind lb vserver <name> <servicegroupName>
```

Example:

```
bind lb vserver lb1 srvc1
bind lb vserver lb1 srvcg1
```

Configure MQTT/MQTT_TLS content switching virtual server.

```
add cs vserver <name> <protocol> <IPAddress> <port>
```

Example:

```
add cs vserver cs1 MQTT 10.106.163.13 1883
```

Configure a content switching action that specifies the target load balancing virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add cs action <name> -targetLBVserver <string> [-comment <string>]
```

Example:

```
add cs action act1 -targetlbvserver lbv1
```

Configure a content switching policy.

```
add cs policy <policyName> [-url <string> | -rule <expression>] –
   action <actName>
```

Example:

```
add cs policy cspol1  -rule  “ MQTT.COMMAND.EQ(CONNECT) && MQTT.CONNECT
   .FLAGS.QOS.eq(2) ”  -action act1
```

Bind the content switching policy to a content switching virtual server that is already configured to redirect to the specific load balancing virtual server.

```
bind cs vserver <virtualServerName> -policyName <policyName> -priority
   <positiveInteger>
```

Example:

```
bind cs vserver cs1  – policyName cspol1 -priority 20
```

Save the configuration.

```
save ns config
```

To configure load balancing for MQTT traffic by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and create a load balancing virtual server of type **MQTT** or **MQTT_TLS**.
2. Create a service or service group of type MQTT.
3. Bind the service to the MQTT virtual server.
4. Click **Save**.

MQTT message length limit

The Citrix ADC appliance treats the messages with message length greater than 65536 bytes as jumbo packets, and discard them by default. The `dropmqttjumbomessage` lb parameter decides whether to process the jumbo packets or not. This parameter is by default set to **YES**, which implies that the jumbo MQTT packets are dropped by default. If this parameter is set to **NO**, the ADC appliance handles even the packets with message length greater than 65536 bytes.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure the ADC appliance to handle jumbo packets by using CLI:

```
Set lb parameter –dropMqttJumboMessage [YES | NO]
```

Example:

```
set lb parameter –dropMqttJumboMessage no
```

Protect a load balancing configuration against failure

September 14, 2021

When a load balancing virtual server fails, or when the virtual server is unable to handle excessive traffic, the load balancing setup can fail. You can protect your load balancing setup against failure by configuring;

- the Citrix ADC appliance to redirect excess traffic to an alternate URL,
- a backup load balancing virtual server, and
- a stateful connection failover.

Redirect client requests to an alternate URL

October 8, 2023

You can redirect requests to an alternate URL by using an HTTP 302 redirect if a load balancing virtual server of type HTTP or HTTPS goes DOWN or is disabled. The alternate URL can provide information about the status of the server. The configured redirect URL is specified in the location header of the HTTP response. The exact URL specified in the response depends on the following configuration options:

- If the configured redirect URL contains only the domain name, such as http://www.sample1.example.com, the redirect URL specified in the HTTP response appends the Uniform Resource Identifier (URI). It is specified in the HTTP request to the configured domain name. For example, if the request contains the GET http://www.sample2.example.com/images/site_nav.png header, then the location header in the redirect response specifies the location: http://www.sample1.example.com/images/site_nav.png header.

  > **Note**
  >
  > The domain names in the request and response can differ. In this topic, the two domains

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> are referred to as sample1.example.com and sample2.example.com to explain the concept.

- If the configured redirect URL contains a complete path, then the redirect response specifies the complete configured URL, irrespective of the URI in the request. For example, the following are such URLs:
  - Requested URL - http://www.redirect.com/en/index.html
  - Redirect URL - http://www.redirect.com/en/site_down.html

The following table lists the preceding configuration options:

Configured Redirect URL	URL in HTTP Request	Header
http://www.sample1.example.com	http://www.sample2.example.com/en/index.html	http://v
http://www.sample1.example.com/en/error.html	http://www.sample2.example.com/en/index.html	http://v

> **Note**
>
> - When configuring a redirect URL, the http://example.com URL is not the same as the http://example.com/ URL, because the latter contains the complete path to the Webroot path, /.
> - If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when both the primary and backup virtual servers are DOWN.

To configure a virtual server to redirect the client request to a URL by using the CLI

1. Create a load balancing virtual server.

   ```
   set lb vserver -redirect url
   ```

2. Verify that the redirect URL option is working as expected. Disable the virtual server.

   ```
   disable vserver <vserver_name>
   ```

3. Access the website URL from a web browser to verify that the request is redirected as expected. You might have to clear the web browser cache and make a new connection before accessing the website.
4. Enable virtual server.

   ```
   enable vserver <vserver_name>
   ```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure a virtual server to redirect the client request to a URL by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, to add a new virtual server, click **Add**.
3. To edit an existing virtual server, select the virtual server from the list and click **Edit**.
4. On the **Advanced Settings** tab, click **Protection**. In the **Redirect URL** field, type the redirect URL (for example, http://www.newdomain.com/mysite/maintenance).
5. Click **OK**.

Configure a backup load balancing virtual server

January 27, 2025

You can configure the Citrix ADC appliance to direct requests to a backup virtual server when the primary load balancing virtual server is DOWN or unavailable. The backup virtual server is a proxy and is transparent to the client. The appliance can also send a notification message to the client regarding the site outage.

> Note:
>
> The backup virtual server continues to handle the existing connections, even after the primary virtual server is deleted or disabled.

You can configure a backup load balancing virtual server when you create it, or you can change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating cascading backup virtual servers. The maximum depth of cascading backup virtual servers is 10.

If you have multiple virtual servers that connect to two servers, you have a choice for what happens if the primary virtual server goes DOWN and then comes back up. The default behavior is for the primary virtual server to resume its role as primary. However, you can configure the backup virtual server to remain in control when it takes over. For example, you can sync the updates on the backup virtual server to the primary virtual server and then manually force the original primary server to resume its role. In this case, you can designate the backup virtual server to remain in control when the primary virtual server goes DOWN and then comes back up.

You can configure a redirect URL on the primary load balancing virtual server as a fallback for when both the primary and the backup virtual servers are DOWN or have reached their threshold for handling requests. When services bound to virtual servers are OUT OF SERVICE, the appliance uses the redirect URL.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when the primary and backup virtual servers are down.

To set a backup virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <vServerName> -backupVserver <BackupVServerName> [-
    disablePrimaryOnDown <ENABLED|DISABLED>]
```

Example:

```
set lb vserver Vserver-LB-1 -backupVserver Vserver-LB-2 -
    disablePrimaryOnDown ENABLED
```

To set a backup virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and select a backup virtual server.
3. If you want the backup virtual server to remain in control until you manually enable the primary virtual server even if the primary virtual server comes back up, select **Disable Primary When Down**.

> **Note:** Starting from Citrix ADC version 12.1 build 51.xx, the GUI displays the effective state of that server indicating if the backup is active or not.
>
> The effective state of the current server can be one of the following:
>
> - **UP** –Indicates that the server is UP
> - **DOWN** –Indicates that the server is DOWN
> - **UP (Backup Active)** –Indicates that either the primary or the secondary virtual server is UP and traffic is directed to the backup virtual server.
> - **DOWN (Backup Active)** –Indicates that both the primary and the backup virtual servers are down and traffic is routed to the backup virtual server.
>
> When the **Disable Primary When Down** option is enabled on the primary virtual server and the primary server goes DOWN and is back UP again, the traffic is still served by the backup virtual server until the primary virtual server is re-enabled explicitly. You can use the command `enable lb vserver <vserver_name>` command to re-enable the primary virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure spillover

September 14, 2021

A spillover configuration on the appliance consists of a primary virtual server that is configured with a spillover method, a spillover threshold, and a backup virtual server. Backup virtual servers can also be configured for spillover, creating a chain of backup virtual servers.

The spillover method specifies the operational condition on which you want to base your spillover configuration (for example, the number of established connections, bandwidth, or combined health of the server farm). When a new connection arrives, the appliance verifies that the primary virtual server is up and compares the operational condition with the configured spillover threshold. If the threshold is reached, the spillover feature diverts new connections to the first available virtual server in the backup chain. The backup virtual server manages the connections it receives until the load on the primary falls below the threshold.

If you configure spillover persistence, the backup virtual server continues to process the connections it received, even after the load on the primary falls below the threshold. If you configure spillover persistence and a spillover persistence timeout, the backup virtual server processes connections for only the specified period after the load on the primary falls below the threshold.

Note: Usually, spillover is triggered if the value associated with the spillover method exceeds the threshold (for example, number of connections). However with the server-health spillover method, spillover is triggered if the health of the server farm falls below the threshold.

You can configure spillover in one of the following ways:

- Specify a predefined spillover method. Four predefined methods are available, and they fulfill common spillover requirements.
- Configure policy based spillover. In policy based spillover, you use a Citrix ADC rule to specify the conditions for spillover to occur. Citrix ADC rules give you the flexibility to configure spillover for various operational conditions.

Use policy based spillover if a predefined method does not satisfy your requirements. If you configure both for a primary virtual server, the policy based spillover configuration takes precedence over the predefined method.

First, you create the primary virtual server and the virtual servers that you need for the backup chain. You set up the backup chain by specifying one virtual server as the backup for the primary (that is, you create a secondary virtual server), a virtual server as the backup for the secondary (that is, you create a tertiary virtual server), and so on. Then, you configure spillover by either specifying a predefined spillover method or creating and binding spillover policies.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For instructions for assigning a virtual server as the backup for another virtual server, see Configuring a Backup Load Balancing Virtual Server.

Configure a predefined spillover method

Predefined spillover methods fulfill some of the more common spillover requirements. To use one of the predefined spillover methods, you configure spillover parameters on the primary virtual server. To create a chain of backup virtual servers, you also configure spillover parameters on backup virtual servers.

If the backup virtual servers reach their own threshold values, and the service type is TCP, the Citrix ADC appliance sends clients a TCP reset. For service types HTTP, SSL, and RTSP, it diverts new requests to the redirect URL configured for the primary virtual server. A redirect URL can be specified for only HTTP, SSL, and RTSP virtual servers. If a redirect URL is not configured, the Citrix ADC appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

Note: With RTSP virtual servers, the Citrix ADC appliance uses only data connections for spillover. If the backup RTSP virtual server is not available, the requests are redirected to an RTSP URL and an RTSP redirect message is sent to the client.

To configure a predefined spillover method for a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -soMethod <spillOverType> -soThreshold <
    positiveInteger> -soPersistence ENABLED -soPersistenceTimeout <
    positiveInteger>
```

Example

```
set lb vserver Vserver-LB-1 -soMethod Connection -soThreshold 1000 -
    soPersistence enabled -soPersistenceTimeout 2
```

To configure a predefined spillover method for a virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and set the spillover parameters.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure policy based spillover

Spillover policies, which are based on rules (expressions), enable you to configure the appliance for a wider range of spillover scenarios. For example, you can configure spillover based on the virtual server's response time, or based on the number of connections in the virtual server's surge queue.

To configure policy based spillover, first create a spillover action. You then select the expression that you want to use in the spillover policy, configure the policy, and associate the action with it. Finally, you bind the spillover policy to a load balancing, content switching, or global server load balancing virtual server. You can bind multiple spillover policies to a virtual server, with priority numbers. The appliance evaluates the spillover policies in ascending order of priority numbers and performs the action associated with the last policy to evaluate to TRUE.

A virtual server can also have a backup action. The backup action is performed if the virtual server does not have one or more backup virtual servers, or if all backup virtual servers are DOWN, disabled, or have reached their own spillover limits.

When a spillover policy results in an UNDEF condition (an exception thrown when the result of policy evaluation is undefined), an UNDEF action is performed. The UNDEF action is always ACCEPT. You cannot specify an UNDEF action of your choice.

Configuring a Spillover Action

A spillover action is performed when the spillover policy with which it is associated evaluates to TRUE. Currently, SPILLOVER is the only supported spillover action.

To configure policy based spillover by using the command line interface At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```
add spillover action <name> -action SPILLOVER

show spillover action <name>
```

Example

```
add spillover action mySoAction -action SPILLOVER
Done
```

```
show spillover action mySoAction
1) Name: mySoAction Action: SPILLOVER
Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Selecting an Expression for the Spillover Policy

In the policy expression, you can use any virtual-server based expression that returns a Boolean value. For example, you can use one of the following expressions:

```
SYS.VSERVER("vserver").RESPTIME.GT(<int>)
SYS.VSERVER("vserver").STATE.EQ(" <string> "), and
SYS.VSERVER("vserver").THROUGHPUT.LT    (<int>)
```

In addition to the existing functions such as RESPTIME, STATE, and THROUGHPUT, you can use the following virtual server based functions that have been introduced with this feature:

`Averagesurgecount` Returns the average number of requests in the surge queues of active services. Returns 0 (zero) if there are no active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

`Activeservices` Returns the number of active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

`Activetransactions` Returns the value of the virtual-server-level counter for current active transactions.

is_dynamic_limit_reached Returns a Boolean TRUE if the number of connections that the virtual server manages is equal to the dynamically calculated threshold. The dynamic threshold is the sum of the maximum client (Max Clients) settings of the bound services that are UP.

You can use a policy expression to implement any of the predefined spillover methods. The following table maps the predefined spillover methods to the expressions you can use to implement them:

Table 1. Converting predefined spillover methods to policy expressions

Predefined spillover method	Corresponding expression
CONNECTION	SYS.VSERVER("<vserver-name>").CONNECTIONS, used with the GT(int) arithmetic function.
BANDWIDTH	SYS.VSERVER("<vserver-name>").THROUGHPUT, used with the GT(int) arithmetic function.
HEALTH	SYS.VSERVER("<vserver-name>").HEALTH, used with the LT(int) arithmetic function.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Predefined spillover method	Corresponding expression
DYNAMICCONNECTION	SYS.VSERVER("<vserver-name>").IS_DYNAMIC_LIMIT_REACHED **Note**: If you implement policy based spillover by using the IS_DYNAMIC_LIMIT_REACHED function, you must also configure the predefined DYNAMICCONNECTION method for the virtual server, so that the statistics required for spillover to work are collected.

Configuring a Spillover Policy

A spillover policy uses a Boolean expression as a rule to specify the conditions that must be met for spillover to occur.

To configure a spillover policy by using the command line interface At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```
add spillover policy <name> -rule <expression> -action <string> [-comment <string>]

show spillover policy <name>
```

Example

```
> add spillover policy mySoPolicy -rule SYS.VSERVER("v1").RESPTIME.GT (50) -action mySoAction -comment "Triggers spillover when the vserver's response time is greater than 50 ms."
Done

> show spillover policy mySoPolicy

1)  Name: mySoPolicy Rule: "SYS.VSERVER("v1").RESPTIME.GT(50)" Action: mySoAction Hits: 0 ActivePolicy: 0
Comment: "Triggers spillover when the vserver's response time is greater than 50 ms."
Done
>
```

Binding a Spillover Policy to a Virtual Server

You can bind a spillover policy to load balancing, content switching, or global server load balancing virtual servers). You can bind multiple policies to a virtual server, with Goto expressions controlling

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

the flow of evaluation.

To bind a spillover policy to a virtual server by using the command line interface At the command prompt, type the following commands to bind a spillover policy to a load balancing, content switching, or global server load balancing virtual server and verify the configuration:

```
bind (lb | cs | gslb) vserver <name> -policyName <string> -priority <
    positive_integer> [-gotoPriorityExpression <expression>]

show (lb | cs | gslb) vserver <name>
```

Example:

```
> bind lb vserver vserver1 -policyName mySoPolicy -priority 5
Done
> show lb vserver vserver1
vserver1 (2.2.2.12:80) - HTTP Type: ADDRESS
. . .

1)  Spillover Policy Name: mySoPolicy Priority: 5
GotoPriority Expression: END
Flowtype: REQUEST
Done
>
```

Configuring a Backup Action for a Spillover Event

A backup action specifies what to do when the spillover threshold is reached but one or more backup virtual serves are either not configured or are down, disabled, or have reached their own thresholds.

Note: For the predefined spillover methods that are configured directly on the virtual server (as values of the Spillover Method parameter), the backup action is not configurable. By default, the appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

The backup action is configured on the virtual server. You can configure the virtual server to accept requests (after the threshold specified by the policy is reached), redirect clients to a URL, or simply drop requests even before establishing TCP or SSL connections until the number of requests falls below the threshold. Therefore, lesser memory resources are utilized as the connections are reset even before allocating any data structures.

To configure a backup action for spillover by using the CLI At the command prompt, type the following commands to configure a backup action and verify the configuration:

```
set lb vserver <name> -soBackupAction <soBackupAction>

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
show lb vserver <name>
```

Example:

```
set lb vserver vs1 -soBackupAction REDIRECT -redirectURL `http://www.
   mysite.com/maintenance`
Done
> show lb vserver vs1
vs1 (10.102.29.76:80) - HTTP Type: ADDRESS
State: UP
. . .
Redirect URL: `http://www.mysite.com/maintenance`
. . .
Done
```

To configure a backup action for spillover by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and then specify a spillover backup action.

Connection failover

June 16, 2022

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. In a Citrix ADC High Availability (HA) setup, *connection failover* (or *connection mirroring-CM*) refers to keeping active an established TCP or UDP connection when a failover occurs. The new primary Citrix ADC appliance has information about the connections established before the failover and continues to serve those connections. After failover, the client remains connected to the same physical server. The new primary appliance synchronizes the information with the new secondary appliance. If the L2Conn parameter is set, Layer 2 connection parameters are also synchronized with the secondary.

> Note:
>
> Consider a HA setup, where a client establishes a session with the primary node, which in turn establishes a session with the back end server. When a failover is triggered in this state, the packets received on a new primary from the existing client and server nodes are treated as stale packets, and the client and server connections are reset. Whereas if stateless connection failover is enabled (USIP is ON), after the failover, the connections are not reset when you receive packets from client or server nodes. Instead, the client and server connections are created dynamically.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

You can set up connection failover in either stateless or stateful mode. In the stateless connection failover mode, the HA nodes do not exchange any information about the connections that are failed over. This method has no runtime overhead.

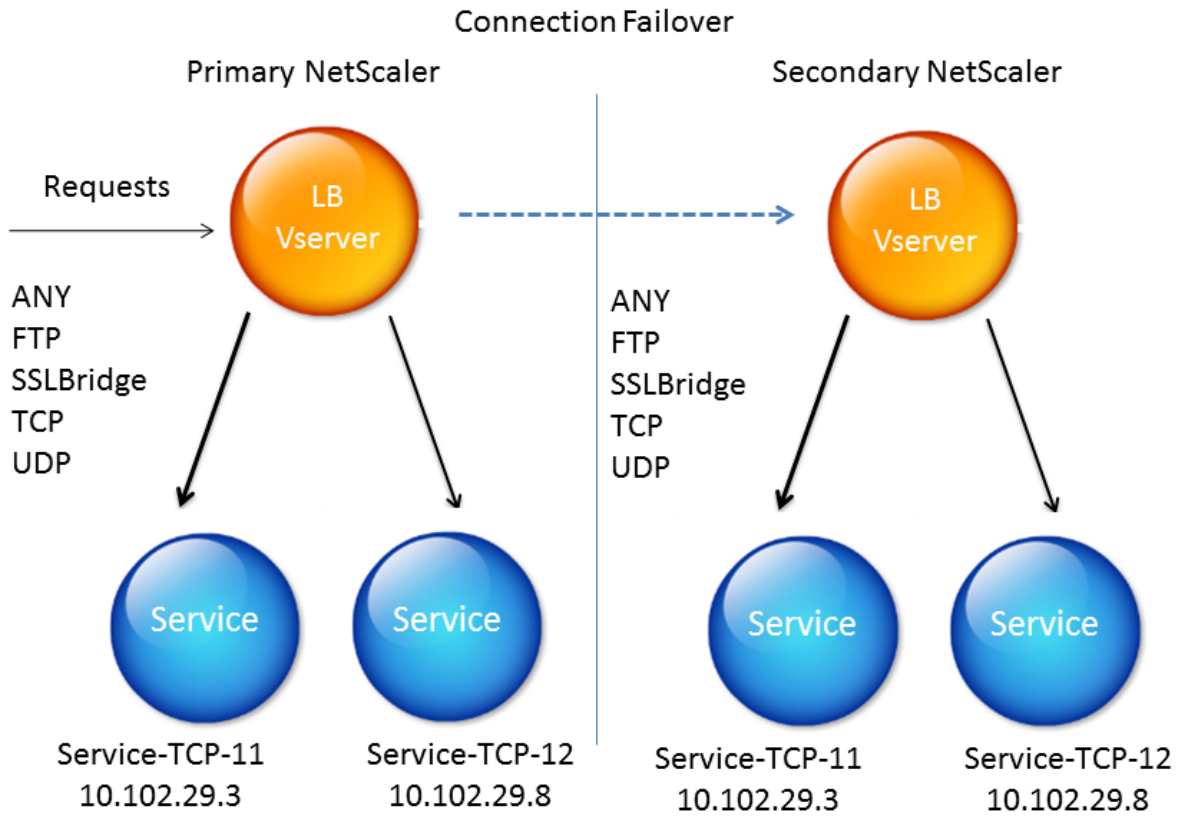
In the stateful connection failover mode, the primary appliance synchronizes the data of the failed-over connections with the new secondary appliance.

Connection failover is helpful if your deployment has long lasting connections. For example, if you are downloading a large file over FTP and a failover occurs during the download, the connection breaks and the download is aborted. However, if you configure the connection failover in stateful mode, the download continues even after the failover.

How connection failover works on Citrix ADC appliances

In a stateless connection failover, the new primary appliance tries to re-create the packet flow according to the information contained in the packets it receives.

In stateful failover, to maintain current information about the mirrored connections, the primary appliance sends messages to the secondary appliance. The secondary appliance maintains the data related to the packets but uses it only in the event of a failover. If a failover occurs, the new primary (old secondary) appliance starts using the stored data about the mirrored connections and accepting traffic. During the transition period, the client and server might experience a brief disruption and retransmissions.



Note:

Verify that the primary appliance is able to authorize itself on the secondary appliance. To verify the correct configuration of the passwords, use the show `rpcnode` command from the command line or use the RPC option of the **Network** menu in the GUI.

A basic HA configuration with connection failover contains the entities shown in the following figure.

Figure 1. Connection Failover Entity Diagram

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note

Connection failover is not supported after either of the following events:

```
- An upgrade to a later release.
- An upgrade to a later build within the same release, if the new
    build uses a different HA version.
```

Supported setup

Connection failover can be configured only on load balancing virtual servers. It cannot be configured on content switching virtual servers. If you enable connection failover on load balancing virtual servers that are attached to a content switching virtual server, connection failover does not work because the load balancing virtual servers do not initially accept the traffic.

The following table describes the setup supported for connection failover.

Table 1. Connection Failover - Supported Setup

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Setting	Stateless	Stateful
Service type	ANY.	ANY, UDP, TCP, FTP, SSL_BRIDGE.
Load balancing methods	All methods supported for the service type ANY. However, if Source IP persistence is not set, the SRCIPSRCPORTHASH method must be used.	All methods applicable to the supported service types.
Persistence types	SOURCEIP persistence.	All types applicable to the supported service types are supported.
USIP	Must be ON.	No restriction. It can be ON or OFF.
Service bindings	Service can be bound to only one virtual server.	Service can be bound to one or more virtual servers.
Internet Protocol (IP) versions	IPv4 and IPv6	IPV4 and IPv6
Redundancy support	Clustering and high availability	High availability

> Note:
>
> Stateful connection failover is supported only for connection-based switching services, for example, TCP. Because HTTP uses request-based switching, it does not support connection failover. In SSL, the existing connections are reset after the failover.

Features affected by connection failover

The following table lists the features affected if connection failover is configured.

Table 2. How Connection Failover Affects Citrix ADC Features

Feature	Impact of Connection Failover
SYN protection	For any connection, if a failover occurs after the appliance issues SYN-ACK but before it receives the final ACK, the connection is not supported by the connection failover. The client must reissue the request to establish the connection.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Feature	Impact of Connection Failover
Surge protection	If the failover occurs before a connection with the server is established, the new primary appliance tries to establish the connection with the server. It also retransmits all the packets held during surge protection.
Access down	If enabled, the access-down functionality takes precedence over the connection failover.
Application firewall	The Application firewall feature is not supported.
INC	Independent network configuration is not supported in the high availability mode.
TCP buffering	TCP buffering is not compatible with connection mirroring.
Close on response	After failover, the NATPCBs might not be closed on response.

To configure connection failover by using GUI

Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**. Open the virtual server, and in **Advanced Settings**, click **Protection**, and select **Connection Failover** as **Stateful**.

To configure connection failover by using CLI

At the command prompt:

```
set lb vserver <vServerName> -connFailover <Value>
show lb vserver <vServerName>
```

Example:

```
set lb vserver Vserver-LB-1 -connFailover stateful
Done
```

When connection failover is disabled on a virtual server, the resources allocated to the virtual server are freed.

To disable connection failover by using CLI

At the command prompt:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set lb vserver <vServerName> -connFailover <Value>
show lb vserver <vServerName>
```

Example:

```
set lb vserver Vserver-LB-1 -connFailover disable
Done
```

To disable connection failover by using GUI

Navigate to **Traffic Management**> **Load Balancing**> **Virtual Servers**. Open the virtual server, in **Protection**, select **Connection Failover** as Disabled.

Flush the surge queue

September 14, 2021

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. The Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established and thus avoid overloads.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between the client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection. The length of a surge queue decreases in any of the following conditions:

- A request in the queue gets sent to the server.
- A request gets timed out and is removed from the queue.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If the surge queue for a service or service group becomes too long, you might want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed. The other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN, or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the CLI

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while running the command, the surge queue of the specified entity is flushed. If more than one entity has the same name, the appliance flushes the surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while running the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you run the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
```

Examples

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
flush ns surgeQ -name SVC1ANZGB -serverName 10.10.10.1 80
```

The previous command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

```
flush ns surgeQ
```

The previous command flushes all the surge queues on the appliance.

To flush a surge queue by using the GUI

Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers**, select a virtual server and, in the Action list, select **Flush Surge Queue**.

Manage a load balancing setup

September 14, 2021

An existing Load Balancing setup does not require a great deal of work to maintain as long as it is unchanged, but most do not remain unchanged for long. Increasing load requires new load-balanced servers and eventually new Citrix ADC appliances, which must be configured and added to the existing setup. Old servers wear out and must be replaced, requiring removal of some servers and addition of others. Upgrades to your networking equipment or changes to topology might also require modifications to your load balancing setup. Therefore, you need to perform operations on server objects, services, and virtual servers. The Visualizer can display your configuration graphically, and you can perform operations on the entities in the display. You can also take advantage of other features that facilitate management of the traffic through your load balancing setup.

Manage server objects

September 14, 2021

During basic load balancing setup, when you create a service, a server object with the IP address of the service is created, if one does not exist. If you prefer for your service objects named with domain names rather than IP addresses, you might also have created one or more server objects manually. You can enable, disable, or remove any server object.

When you enable or disable a server object, you enable or disable all services associated with the server object. When you refresh the Citrix ADC appliance after disabling a server object, the state of

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

its service appears as OUT OF SERVICE. If you specify a wait time when disabling a server object, the server object continues to handle established connections for the specified amount of time, but rejects new connections. If you remove a server object, the service to which it is bound is also deleted.

To enable a server by using the CLI

At the command prompt, type:

```
enable server <name>
```

Example:

```
enable server 10.102.29.5
```

To enable or disable a server object by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Servers**.
2. Select the server and, in the Action list, select **Enable** or **Disable**.

To disable a server object by using the CLI

At the command prompt, type:

```
disable server <name> <delay>
```

Example:

```
disable server 10.102.29.5 30
```

To remove a server object by using the CLI

At the command prompt, type:

```
rm server <name>
```

Example:

```
rm server 10.102.29.5
```

To remove a server object by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Servers**.
2. Select a server, and click **Remove**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Manage services

October 16, 2023

Services are enabled by default when you create them. You can disable or enable each service individually. When disabling a service, you normally specify a wait time during which the service continues to handle established connections, but rejects new ones, before shutting down. If you do not specify a wait time, the service shuts down immediately. During the wait time, the service's state is OUT OF SERVICE.

You can remove a service when it is no longer used. When you remove a service, it is unbound from its virtual server and deleted from the Citrix ADC configuration.

To enable or disable a service by using the CLI

At the command prompt, type:

```
enable service <name>

disable service <name> <DelayInSeconds>
```

Examples:

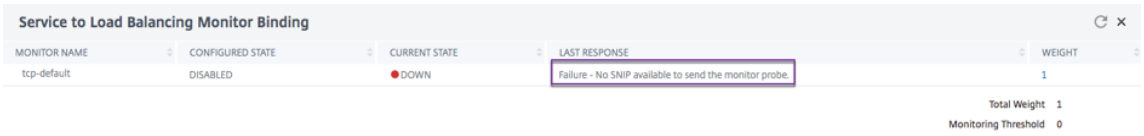
```
enable service Service-HTTP-1
disable service Service-HTTP-1 30
```

To enable or disable a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service and, in the **Action** list, select **Enable** or **Disable**.

Identify the cause for the service state marked DOWN by using the GUI

Starting from Citrix ADC version 13.0 build 41.20, you can view the monitor probe information on the GUI for the services that are DOWN without navigating to the monitor binding interface. The value in the **Server State** column of the Services page is clickable. You can click **DOWN** to identify the root cause because of which the service is marked DOWN.



1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Click **DOWN** in the **Server State** column corresponding to the service that is DOWN.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The Service to Load Balancing Monitor Binding page appears.

The **Last Response** column displays the reason because of which the service is marked DOWN.

Manage a load balancing virtual server

October 16, 2023

Virtual servers are enabled by default when you create them. You can disable and enable virtual servers manually. If you disable a virtual server, the virtual service's state appears as OUT OF SERVICE. When this happens, the virtual server terminates all connections, either immediately or after allowing existing connections to complete, depending on the setting of the downStateFLush parameter. If downStateFLush is ENABLED (default), all the connections are flushed. If DISABLED, the virtual server continues to serve requests on existing connections.

You remove a virtual server only when you no longer require the virtual server. Before you remove it, you must unbind all services from it.

To enable or disable a virtual server by using the CLI

At the command prompt, type:

```
enable lb vserver <name>
```

```
disable lb vserver <name>
```

Examples:

```
enable lb vserver Vserver-LB-1
disable lb vserver Vserver-LB-1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable or disable a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a virtual server, and in the **Action** list, select **Enable** or **Disable**.

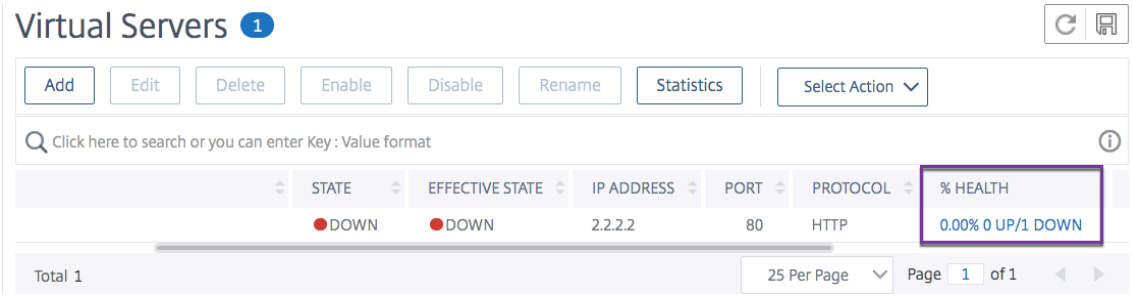
To unbind a service from a virtual server by using the CLI

At the command prompt, type:

```
unbind lb vserver <name> <serviceName>
```

Example:

```
unbind lb vserver Vserver-LB-1 Service-HTTP-1
```



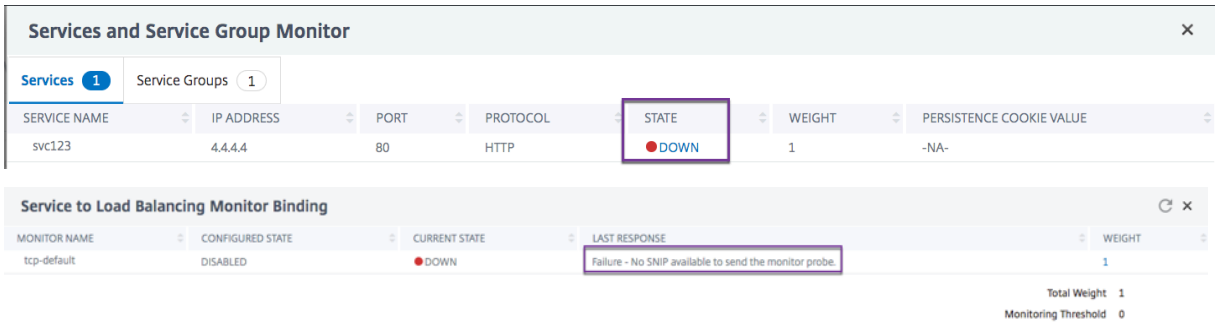
To unbind a service from a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the **Services** section.
3. Select a service and click **Unbind**.

Identify the cause for the virtual server state marked DOWN by using the GUI

Starting from Citrix ADC version 13.0 build 41.20, you can view the monitor probe information on the GUI for the virtual servers that are DOWN without navigating to the monitor binding interface. The value in the **% HEALTH** column of the Virtual Server page is clickable. You can click the value in the **% HEALTH** column to identify the root cause because of which the virtual server is marked DOWN.

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Click the value in the **% HEALTH** column corresponding to the virtual server that is down.

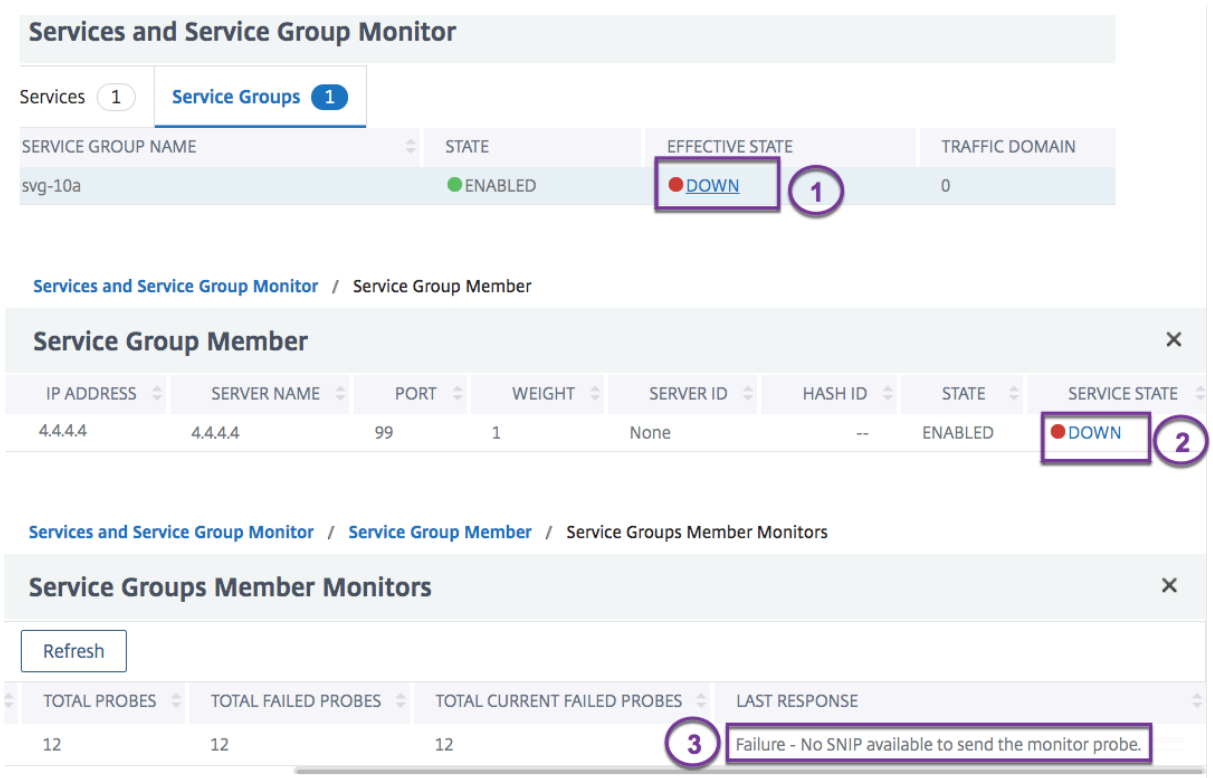


The Service and Service Group Monitor page appears. The services and service groups bound to this virtual server are displayed in the respective tabs.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If you are using services bound to load balancing virtual, perform the following:

In the **Services** tab, click **DOWN** corresponding to the service that is down.



The **Last Response** column in the Service to Load Balancing Monitor Binding page displays the reason because of which the virtual server is marked down.

If you are using service groups bound to load balancing virtual, perform the following:

In the **Service Groups** tab, Click **DOWN** in the Services and Service Group Monitor page and then click **DOWN** in the Service Group Member page.

The **Last Response** column in the Service Groups Member Monitors page displays the reason because of which the virtual server is marked down.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Load balancing visualizer

October 8, 2023

The Load Balancing Visualizer is a tool that you can use to view and modify the load balancing configuration in a graphical format. Following is an example of the Visualizer display.

You can use the visualizer to view the following:

- The services and service groups that are bound to a virtual server.
- The monitors that are bound to each service.
- The policies that are bound to the virtual server.
- The policy labels, if configured.
- Configuration details of any displayed element.

You can also use the Visualizer to add and bind new objects, modify existing ones, and enable or disable objects. Most configuration elements displayed in the Visualizer appear under the same names as in other parts of the configuration utility. However, unlike the rest of the configuration utility, the Visualizer groups services that have the same configuration details and monitor bindings into an entity called a service container.

A service container is set of similar services and service groups that are bound to a single load balancing virtual server. The services in the container have the same properties, except for the name, IP address, and port, and their monitor bindings must have the same weight and binding state. When you bind a new service to a virtual server, it is placed into an existing container if its configuration and monitor bindings match those of other services. Otherwise, it is placed in its own container.

The following procedures provide only the basic steps for using the Visualizer. Because the Visualizer duplicates functionality in other areas of the Load Balancing feature, other methods of viewing or configuring all the settings that can be configured in the Visualizer are provided throughout the Load Balancing documentation.

Note: The Visualizer requires a graphic interface, so it is available only through the configuration utility.

To view load balancing virtual server properties by using the Visualizer

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To view configuration details for services, service groups, and monitors by using the Visualizer

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.
3. In the Load Balancing Visualizer dialog box, double-click the entity to view the configuration details of the entity that is bound to this virtual server, you can do the following:

To view configuration details for policies and policy labels by using the Visualizer in the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, double-click the policies entity to view the policies that are bound to this virtual server.

To modify a resource in a load balancing configuration by using the Visualizer

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, on the Visualizer image, double-click the resource that you want to modify.

To add a load balancing configuration by using the Visualizer

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, click **+** to add the resource.

Manage client traffic

September 14, 2021

Managing client connections properly helps to ensure that your applications remain available to users even when your Citrix ADC appliance is experiencing high loads. Various load balancing features and other features available on the appliance can be integrated into a load balancing setup to process load more efficiently, divert it when necessary, and prioritize the tasks that the appliance must perform:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Sessionless load balancing.** You can configure sessionless load balancing virtual servers and perform load balancing without creating sessions in configurations that use DSR or intrusion detection systems (IDS).
- **Integrated caching.** You can redirect HTTP requests to a cache.
- **Priority queuing.** You can direct requests based on priority, by integrating your configuration with the Priority Queuing feature.
- **SureConnect.** You can use load balancing with the Sure Connect feature to redirect important requests to a custom webpage, insulating them from delays due to network congestion.
- **Delayed cleanup.** You can configure delayed cleanup of virtual server connections to prevent the cleanup process from using CPU cycles during periods when the Citrix ADC appliance is experiencing high loads.
- **Rewrite.** You can use the Rewrite feature to modify port and protocol when performing HTTP redirection, or insert the virtual server IP address and port into a custom Request header.
- **RTSP NAT.**
- **Rate-based monitoring.** You can enable rate-based monitoring to divert excess traffic.
- **Layer 2 Parameters.** You can configure a virtual server to use the L2 parameters to identify a connection.
- **ICMP Response**. You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the `ICMP VSERVER RESPONSE`. The following settings can be made on a virtual server:
  - When you set `ICMP VSERVER RESPONSE` to PASSIVE on all virtual servers, the appliance always responds.
  - When you set `ICMP VSERVER RESPONSE` to ACTIVE on all virtual servers, the appliance responds even if one virtual server is UP.
  - When you set `ICMP VSERVER RESPONSE` to ACTIVE on some and PASSIVE on others, the appliance responds even if one virtual server set to ACTIVE is UP.

Configure sessionless load balancing virtual servers

September 14, 2021

When the Citrix ADC appliance performs load balancing, it creates and maintains sessions between clients and servers. The maintenance of session information places a significant load on the appliance resources, and sessions might not be needed in scenarios such as a direct server return (DSR) setup and the load balancing of intrusion detection systems (IDS). To avoid creating sessions when they are not necessary, you can configure a virtual server on the appliance for sessionless load balancing. In sessionless load balancing, the appliance carries out load balancing on a per-packet basis.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Sessionless load balancing can operate in MAC-based forwarding mode or IP-based forwarding mode.

For MAC-based forwarding, the IP address of the sessionless virtual server must be specified on all the physical servers to which the traffic is forwarded.

For IP-based forwarding in sessionless load balancing, the IP address and port of the virtual server need not be specified on the physical servers, because this information is included in the forwarded packets. When forwarding a packet from the client to the physical server, the appliance leaves client details such as IP address and port unchanged and adds the IP address and port of the destination.

Supported setup

Citrix ADC sessionless load balancing supports the following service types and load balancing methods:

Service Types

- ANY for MAC-based redirection
- ANY, DNS, and UDP for IP-based redirection

Load Balancing Methods

- Round Robin
- Least Bandwidth
- LRTM (Least response time method)
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port Hash
- Custom Load

Limitations

Sessionless load balancing has the following limitations:

- The appliance must be deployed in two-arm mode.
- A service must be bound to only one virtual server.
- Sessionless load balancing is not supported for service groups.
- Sessionless load balancing is not supported for domain based services (DBS services).

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Sessionless load balancing in the IP mode is not supported for a virtual server that is configured as a backup to a primary virtual server.
- You cannot enable spillover mode.
- For all the services bound to a sessionless load balancing virtual server, the Use Source IP (USIP) option must be enabled.
- For a wildcard virtual server or service, the destination IP address is not changed.

Note:

- While configuring a virtual server for sessionless load balancing, explicitly specify a supported load balancing method. The default method, Least Connection, cannot be used for sessionless load balancing.
- To configure sessionless load balancing in MAC-based redirection mode on a virtual server, the MAC-based forwarding option must be enabled on the Citrix ADC appliance.

To add a sessionless virtual server by using the CLI

At the command prompt, type the following commands to add a sessionless virtual server and verify the configuration:

```
add lb vserver <name>@ <serviceType> <IPAddress>@ <port> -m <
   redirectionMode> -sessionless <(ENABLED|DISABLED)> -lbMethod <
   load_balancing_method>

show lb vserver <name>
```

Example:

```
 add lb vserver sesslessv1 any 11.11.12.123 54 -sessionless ENABLED -
    lbMethod roundrobin -m ip
      Done
 show lb vserver sesslessv1
      sesslessv1 (11.11.12.123:54) - ANY Type: ADDRESS
      State: DOWN
      ...
      Effective State: DOWN
      Client Idle Timeout: 120 sec
      Down state flush: ENABLED
      ...
      Persistence: NONE
      Sessionless LB: ENABLED
      Connection Failover: DISABLED
      L2Conn: OFF
      1) Policy : cmp_text Priority:8680 Inherited
      2) Policy : cmp_nocmp_ie60 Priority:8690 Inherited
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure sessionless load balancing on an existing virtual server

At the command prompt, type:

```
set lb vserver <name>@ -m <redirectionMode> -sessionless <(ENABLED|
    DISABLED)> -lbMethod <load_balancing_method>
```

Example:

```
set lb vserver sesslessv1 -m mac -sessionless ENABLED -lbmethod lrtm
  Done
```

> **Note**
>
> For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

To configure a sessionless virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in Advanced Settings, click Traffic Settings, and then select Sessionless Load Balancing.

Redirect HTTP requests to a cache

September 14, 2021

The Citrix ADC cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the impact of responding to HTTP requests and improve your website performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the Citrix ADC appliance sends cacheable HTTP requests to the cache, and non-cacheable HTTP requests to the origin Web server.

To configure cache redirection on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -cacheable <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -cacheable yes
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure cache redirection on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Cacheable.

Direct requests according to priority

September 16, 2021

> **Warning:**
>
> Priority Queuing (PQ) deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. However, Priority Queuing (PQ) is removed and no longer available on the Citrix ADC appliance release 13.1 onwards. For more information, see AppQoE topic.

The Citrix ADC appliance supports prioritization of client requests with its priority queuing feature. This feature allows you to designate certain requests, such as those from important clients, as priority requests and sends them to the "front of the line,"so that the appliance responds to them first. This allows you to provide uninterrupted service to those clients through demand surges or DDoS attacks on your website.

To configure priority queuing on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -pq <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -pq yes
```

To configure priority queuing on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Priority Queuing.

Note: Configure priority queuing globally for it to function correctly.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Direct requests to a custom webpage

September 16, 2021

> **Warning:**
>
> SureConnect is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. However, SureConnect is removed and no longer available on the Citrix ADC appliance release 13.1 onwards. For more information, see AppQoE topic.

The Citrix ADC appliance provides the SureConnect option to ensure that web applications respond despite delays caused by limited server capacity or processing speed. SureConnect does this by displaying an alternative webpage of your choice when the server that hosts the primary webpage is either unavailable or responding slowly.

To configure SureConnect on a virtual server, you must first configure the alternative content. For information about configuring a SureConnect website, see SureConnect. After you configure the website, enable SureConnect on the load balancing virtual server to put your SureConnect custom webpage in use.

Note: For SureConnect to function correctly, you must configure it globally.

To enable SureConnect on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -sc <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -sc yes
```

To enable SureConnect on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select SureConnect.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Enable cleanup of virtual server connections

September 14, 2021

Under certain conditions, you can configure the downStateFlush setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes and health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN.

A virtual server is marked DOWN only when all services bound to it are marked DOWN. When a virtual server goes DOWN, it terminates all connections, either immediately or after allowing existing connections to complete.

Do not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with one service bound to it, Service-TCP-1. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

Vserver-LB-1	Service-TCP-1	State of connections
E	E	Both client and server connections are terminated.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Vserver-LB-1	Service-TCP-1	State of connections
E	D	For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.
D	E	For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated.
D	D	Neither client nor server connections are terminated.

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see Graceful Shutdown of Services.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure the down state flush setting on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -downStateFlush <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -downStateFlush enabled
```

To configure the down state flush setting on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Down State Flush.

Rewrite ports and protocols for HTTP redirection

September 14, 2021

Virtual servers and the services that are bound to them might use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the Citrix ADC appliance to modify the port and the protocol to make sure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

This setting affects only HTTP and HTTPS traffic. If this setting is enabled on a virtual server, the virtual server rewrites the port on redirects, replacing the port used by the service with the port used by the virtual server.

If the virtual server or service is of type SSL, you must enable SSL redirect on the virtual server or service. If both the virtual server and service are of type SSL, enable SSL redirect on the virtual server.

The redirectPortRewrite setting can be used in the following scenarios:

- The virtual server is of type HTTP and the services are of type SSL.
- The virtual server is of type SSL and the services are of type HTTP.
- The virtual server is of type HTTP and the services are of type HTTP.
- The virtual server is of type SSL and the services are of type SSL.

Scenario 1: The virtual server is of type HTTP and services are of type SSL. SSL redirect, and optionally port rewrite, is enabled on the service. If port rewrite is enabled, the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Only SSL redirect is enabled. The virtual server can be configured on any port. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

SSL redirect and port rewrite are enabled. The virtual server is configured on port 80. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com/

SSL redirect and port rewrite are enabled. Virtual server is configured on port 8080. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	http://domain.com:8080/
https://domain.com:444/	http://domain.com:8080/

Scenario 2: The virtual server is of type SSL and services are of type HTTP. If port rewrite is enabled, only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	https://domain.com/
http://domain.com:8080/	https://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	https://domain.com/
http://domain.com:8080/	https://domain.com/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

SSL redirect and port rewrite are enabled. The virtual server is configured on port 444. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	https://domain.com:444/
http://domain.com:8080/	https://domain.com:444/
https://domain.com/	https://domain.com/
https://domain.com:445/	https://domain.com:445/

Scenario 3: The virtual server and service are of type HTTP. Port rewrite must be enabled on the virtual server. Only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

The virtual server is configured on port 80. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com:8080/	http://domain.com/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

The virtual server is configured on port 8080. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com:8080/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:445/	https://domain.com:445/

Scenario 4: The virtual server and service are of type SSL. If port rewrite is enabled, only the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/
https://domain.com:444/	https://domain.com:444/

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com/

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Redirect URL from the Server	Redirect URL sent to the Client
https://domain.com:444/	https://domain.com/

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
http://domain.com/	http://domain.com/
http://domain.com:8080/	http://domain.com:8080/
https://domain.com/	https://domain.com:444/
https://domain.com:445/	https://domain.com:444/

To configure HTTP redirection on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -redirectPortRewrite (ENABLED | DISABLED)
```

Example:

```
set lb vserver Vserver-LB-1 -redirectPortRewrite enabled
```

To configure HTTP redirection on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Rewrite.

To configure SSL Redirect on an SSL virtual server or service by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName> - sslRedirect (ENABLED | DISABLED)

set ssl service <serviceName> - sslRedirect (ENABLED | DISABLED)
```

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set ssl vserver Vserver-SSL-1 -sslRedirect enabled

set ssl service service-SSL-1 -sslRedirect enabled
```

To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click SSL Parameters, and select SSL Redirect.

Insert IP address and port of a virtual server in the request header

September 14, 2021

If you have multiple virtual servers that communicate with different applications on the same service, you must do the following:

Configure the Citrix ADC appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, then you must configure the required header tag on both virtual servers.

Note: This option is not supported for wild card virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the CLI

At the command prompt, type:

```
set lb vserver <name> -insertVserverIPPort <insertVserverIPPort> [<
    vipHeader>]
```

Example:

```
set lb vserver Vserver-LB-1 -insertVserverIPPort VipAddr
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To insert the IP address and port of the virtual server in the client requests by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in the Advanced Settings pane, click **Traffic Settings**, and then select Virtual Server IP Port Insertion and specify a virtual server IP port header.

Use a specified source IP for back-end communication

December 31, 2024

For communication with the physical servers or other peer devices, the Citrix ADC appliance uses an IP address owned by it as the source IP address. The Citrix ADC appliance maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, the appliance decides which IP address to use. This address pool is used for sending traffic and monitor probes.

In many situations, you might want the appliance to use a specific IP address or any IP address from a specific set of IP addresses for back-end communications. The following are a few examples:

- A server can distinguish monitor probes from traffic if the source IP address used for monitor probes belongs to a specific set.
- To improve server security, a server might be configured to respond to requests from a specific set of IP addresses or, sometimes, from a single specific IP address. In such a case, the appliance can use only the IP addresses accepted by the server as the source IP address.
- The appliance can manage its internal connections efficiently if it can distribute its IP addresses into IP sets and use an address from a set only for connecting to a specific service.

To configure the appliance to use a specified source IP address, create net profiles (network profiles) and configure the appliance entities to use the profile. A net profile can be bound to load balancing or content switching virtual servers, Citrix Gateway VPN virtual servers, services, service groups, or monitors. A net profile has Citrix ADC owned IP addresses (SNIPs and VIPs) that can be used as the source IP address. It can be a single IP address or a set of IP addresses, referred to as an IP set. If a net profile has an IP set, the appliance dynamically selects an IP address from the IP set at the time of connection. If a profile has a single IP address, the same IP address is used as the source IP.

If a net profile is bound to a load balancing or content switching virtual server, the profile is used for sending traffic to all the services bound to it. If a net profile is bound to a service group, the appliance uses the profile for all the members of the service group. If a net profile is bound to a monitor, the appliance uses the profile for all the probes sent from the monitor.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:**
>
> - When a Citrix ADC appliance uses a VIP address to communicate with a server, it uses session entries to identify whether the traffic destined to the VIP address is a response from a server or a request from a client.
> - You can bind a net profile to Citrix Gateway VPN virtual servers. However, you need to note some points when binding a net profile. For more information, see Points to note when binding a net profile to VPN virtual server.
> - The net profile IPs bound to a service or service group are not only used for sending traffic towards the corresponding back-end servers, but also for the DNS requests that are triggered by any unresolved back-end FQDN.

Usage of a net profile for sending traffic

If the Use Source IP Address (USIP) option is enabled, the appliance uses the IP address of the client and ignores all the net profiles. If the USIP option is not enabled, the appliance selects the source IP in the following manner:

- If there is no net profile on the virtual server or the service or service group, the appliance uses the default method.
- If there is a net profile only on the service or service group, the appliance uses that net profile.
- If there is a net profile only on the virtual server, the appliance uses the net profile.
- If there is a net profile both on the virtual server and service or service group, the appliance uses the net profile bound to the service or service group.

Usage of a net profile for sending monitor probes:

For monitor probes, the appliance selects the source IP in the following manner:

- If there is a net profile bound to the monitor, the appliance uses the net profile of the monitor. It ignores the net profiles bound to the virtual server or service or service group.
- If there is no net profile bound to the monitor,
  - If there is a net profile on the service or service group, the appliance uses the net profile of the service or service group.
  - If there is no net profile even on the service or service group, the appliance uses the default method of selecting a source IP address.
  - If there is no net profile configured on the service or service group but configured on the virtual server, the appliance will not use the virtual server's net profile. Instead, it uses the default method of selecting a source IP address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:**
>
> If there is no net profile bound to a service, the appliance looks for a net profile on the service group if the service is bound to a service group.

To use a specified source IP address for communication, go through the following steps:

1. Create IP sets from the pool of SNIPs and VIPs owned by the Citrix ADC appliance. An IP set can consist of both SNIP and VIP addresses. For instructions, see Creating IP Sets.
2. Create net profiles. For instructions, see Creating a Net Profile.
3. Bind the net profiles to the appliance entities. For instructions, see Binding a Net Profile to a Citrix ADC Entity.

> **Note:**
>
> - A net profile can have only the IP addresses specified as SNIP and VIP on the Citrix ADC appliance.
> - Source IP persistence is not honored for Citrix ADC initiated packets.

Manage net profiles

A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the Citrix ADC appliance uses the addresses specified in the profile as the source IP address.

- For instructions on creating a network profile, see Creating a Network Profile.
- For instructions on binding a network profile to a Citrix ADC entity, see Binding a Net Profile to a Citrix ADC Entity.

Create an IP set

An IP set is a set of IP addresses, which are configured on the Citrix ADC appliance as Subnet IP addresses (SNIPs) or Virtual IP addresses (VIPs). An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it. To create an IP set, add an IP set, and bind Citrix ADC owned IP addresses to it. SNIP addresses and VIP addresses can be present in the same IP set.

To create an IP set by using the CLI

At the command prompt, type the following commands:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add ipset <name>

bind ipset <name> <IPAddress>
```

Or

```
bind ipset <name> <IPAddress>

show ipset [<name>]
```

The preceding command shows the names of all the IP sets on the appliance if you do not pass any name. It shows the IP addresses bound to the specified IP set if you pass a name.

Examples

```
1.
> add ipset skpnwipset
 Done
> bind ipset skpnwipset 21.21.20.1
 Done

2.
 > add ipset testnwipset
 Done
> bind ipset testnwipset 21.21.21.[21-25]
 IPAddress "21.21.21.21" bound
 IPAddress "21.21.21.22" bound
 IPAddress "21.21.21.23" bound
 IPAddress "21.21.21.24" bound
 IPAddress "21.21.21.25" bound
 Done

3.
 > bind ipset skpipset 11.11.11.101
 ERROR: Invalid IP address
[This IP address could not be added because this is not an IP address
   owned by the Citrix ADC appliance]
 > add ns ip 11.11.11.101 255.255.255.0 -type SNIP
 ip "11.11.11.101" added
 Done
 > bind ipset skpipset 11.11.11.101
 IPAddress "11.11.11.101" bound
 Done
4.
> sh ipset
1) Name: ipset-1
2) Name: ipset-2
3) Name: ipset-3
4) Name: skpnewipset
 Done

5.
> sh ipset skpnewipset
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
IP:21.21.21.21
IP:21.21.21.22
IP:21.21.21.23
IP:21.21.21.24
IP:21.21.21.25
 Done
```

To create an IP set by using the GUI

Navigate to **System > Network > IP Sets**, and create an IP set.

Create a net profile

A net profile (network profile) consists of one or more SNIP or VIP addresses of the Citrix ADC appliance.

To create a net profile by using the CLI

At the command prompt, type:

```
add netprofile <name> [-srcIp <srcIpVal>]
```

If the srcIpVal is not provided in this command, it can be provided later by using the `set netprofile` command.

Examples

```
add netprofile skpnetprofile1 -srcIp 21.21.20.1
Done

add netprofile baksnp -srcIp bakipset
Done

set netprofile yahnp -srcIp 12.12.23.1
Done

set netprofile citkbnp -srcIp citkbipset
Done
```

Bind a net profile to a Citrix ADC entity

A net profile can be bound to a load balancing virtual server, service, service group, or a monitor.

Note: You can bind a net profile at the time of creating a Citrix ADC entity or bind it to an existing entity.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To bind a net profile to a server by using the command line interface

You can bind a net profile to load balancing virtual servers and content switching virtual servers. Specify the appropriate virtual server.

At the command prompt, type:

```
set lb vserver <name> -netProfile <net_profile_name>
```

Or

```
set cs vserver <name> -netProfile <net_profile_name>
```

Examples

```
set lb vserver skpnwvs1 -netProfile gntnp
 Done
set cs vserver mmdcsv -netProfile mmdnp
 Done
```

To bind a net profile to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Profiles**, and set a net profile.

To bind a net profile to a service by using the CLI

At the command prompt, type:

```
set service <name> -netProfile <net_profile_name>
```

Example

```
set service brnssvc1 -netProfile brnsnp
 Done
```

To bind a net profile to a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, click **Profiles**, and set a net profile.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To bind a net profile to a service group by using the CLI

At the command prompt, type:

```
set servicegroup <serviceGroupName> -netProfile <net_profile_name>
```

Example

```
set servicegroup ndhsvcgrp -netProfile ndhnp
 Done
```

To bind a net profile to a service group by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**, and open a service group.
2. In Advanced Settings, click **Profiles**, and set a net profile.

To bind a net profile to a monitor by using the CLI

At the command prompt, type:

```
set monitor <monitor_name> -netProfile <net_profile_name>
```

Example

```
set monitor brnsecvmon1 -netProfile brnsmonnp
 Done
```

To bind a net profile to a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Open a monitor, and set the net profile.

Set a time-out value for idle client connections

September 14, 2021

You can configure a virtual server to terminate any idle client connections after a configured time-out period (in seconds) elapses. When you configure this setting, the Citrix ADC appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection. By default, the client idle time-out value is set to 180 seconds.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set a time-out value for idle client connections by using the CLI

At the command prompt, type:

```
set lb vserver <name> -cltTimeout <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -cltTimeout 100
```

To set a time-out value for idle client connections by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In **Advanced Settings,** click **Traffic Settings**, and set the client idle time-out value in seconds.

Manage RTSP connections

September 14, 2021

The Citrix ADC appliance can use either of two topologies—NAT-on mode or NAT-off mode—to load balance RTSP servers. In NAT-on mode, Network Address Translation (NAT) is enabled and configured on the appliance. RTSP requests and responses both pass through the appliance. You must therefore configure the appliance to perform network address translation (NAT) to identify the data connection.

For more information about enabling and configuring NAT, see IP Addressing.

In NAT-off mode, NAT is not enabled and configured. The appliance receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. The load balanced RTSP servers send their responses directly to the client, bypassing the appliance. You must therefore configure the appliance to use Direct Server Return (DSR) mode, and assign publicly accessible FQDNs in DNS to your load balanced RTSP servers.

For more information about enabling and configuring DSR mode, see Configuring Load Balancing in Direct Server Return Mode. For more information about configuring DNS, see Domain Name System. In either case, when you configure RTSP load balancing, you must also configure rtspNat to match the topology of your load balancing setup.

To configure RTSP NAT by using the CLI

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set lb vserver <name>  – RTSPNAT <ValueOfRTSPNAT>
```

Example:

```
set lb vserver vserver-LB-1  – RTSPNAT ON
```

To configure RTSP NAT by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server of type RTSP.
2. In Advanced Settings, click **Traffic Settings**, and select **RTSP Natting**.

Manage client traffic based on traffic rate

September 14, 2021

You can monitor the rate of traffic that flows through load balancing virtual servers and control the behavior of the Citrix ADC appliance based on the traffic rate. For example:

- Throttle the traffic flow if it is too high.
- Cache information based on the traffic rate.
- If the traffic rate is too high, redirect excess traffic to a different load balancing virtual server.
- Apply rate-based monitoring to HTTP and Domain Name System (DNS) requests.

For more information on rate-based policies, see Rate Limiting.

Identify a connection with layer 2 parameters

September 14, 2021

Generally, to identify a connection, the Citrix ADC appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

Enabling the L2Conn parameter for a load balancing virtual server allows multiple TCP and non-TCP connections with the same 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) to co-exist on the Citrix ADC appliance. The appliance uses both the 4-tuple and the Layer 2 parameters to identify TCP and non-TCP connections.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

You can enable the L2Conn option in the following scenarios:

- Multiple VLANs are configured on the Citrix ADC appliance, and a firewall is set up for each VLAN.
- You want the traffic originating from the servers in one VLAN and bound for a virtual server in another VLAN to pass through the firewalls configured for both VLANs.

Therefore, when an nCore Citrix ADC appliance on which the l2Conn parameter is set for one or more load balancing virtual servers is downgraded to a Classic build or to an nCore build that does not support the l2Conn parameter, the load balancing configurations that use the l2Conn parameter become ineffective.

To configure the L2 connection option by using the CLI

At the command prompt, type:

```
add lb vserver <name> <serviceType> <IPAddress>@ <port> -l2Conn ON
```

Example

```
 add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -l2Conn ON
```

To configure the L2 connection option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Layer 2 Parameters.

Configure the Prefer Direct Route option

September 14, 2021

On a wildcard load balancing virtual server if you explicitly configure a route to a destination, by default, the Citrix ADC appliance forwards traffic according to the configured route. If you want the appliance to not look up for the configured route, you can set the Prefer Direct Route option to NO.

If a device is directly connected to a Citrix ADC appliance, the appliance directly forwards traffic to the device. For example, if the destination of a packet is a firewall, the packet need not be routed through another firewall. However, sometimes, you might want the traffic to go through the firewall even if the device is directly connected to it. In such cases, you can set the Prefer Direct Route Option to NO.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: The preferDirectRoute setting is applicable to all the wildcard virtual servers on the Citrix ADC appliance.

To set the Prefer Direct Route option by using the CLI

At the command prompt, type:

```
set lb parameter -preferDirectRoute (YES | NO)
```

Example:

```
set lb parameter -preferDirectRoute YES
```

To set the Prefer Direct Route option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing parameters**.
2. Select Prefer Direct Route.

Use a source port from a specified port range for back-end communication

September 14, 2021

By default, for configurations with USIP option disabled or with USIP and use proxy port options enabled, the Citrix ADC appliance communicates to the servers from a random source port (greater than 1024).

The appliance supports using a source port from a specified port range for communicating to the servers. One of the use cases of this feature is for servers that are configured to identify received traffic belonging to a specific set based on the source port for logging and monitoring purposes. For example, identifying internal and external traffic for logging purpose.

Configuring the Citrix ADC appliance to use a source port from a port range for communicating to the servers consists of the following tasks:

- **Create a net profile and set the source port range parameter**. A source port range parameter specifies one or more port ranges. The appliance randomly selects one of the free ports from the specified port ranges and used it as the source port for each connection to servers.
- **Bind the net profile to load balancing virtual servers, services, or service groups**: A net profile with source port range setting can be bound to a virtual server, service, or a service group

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

of a load balancing configuration. For a connection to a virtual server, the appliance randomly selects one of the free ports from the specified port ranges of a net profile and use this port as the source port for connecting to one of the bound servers.

To specify a source port range or ranges by using the CLI

At the command prompt, type:

```
bind netProfile <name> (-srcPortRange <int[-int]> ...)

show netprofile <name>
```

To specify a source port range or ranges by using the GUI

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Set the **Source Port Range** parameter while adding or modifying NetProfiles.

Sample Configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has partial NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the Citrix ADC appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the Citrix ADC appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
```
> add netprofile CUSTOM-SRCPORT-NP-1
Done
> bind netprofile CUSTOM-SRCPRT-NP-1 – srcportrange 2000-3000

Done
> bind netprofile CUSTOM-SRCPRT-NP-1 – srcportrange 5000-6000

Done
> add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1

Done
```
```

Configure source IP persistency for back-end communication

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

By default, for a load balancing configuration with the USIP option disabled and a net profile bound to a virtual server or services or service groups, the Citrix ADC appliance uses the round robin algorithm to select an IP address from the net profile for communicating with the servers. Because of this selection method, the IP address selected can be different for different sessions of a specific client.

Some situations require that the Citrix ADC appliance route all of a specific client's traffic from the same IP address when sending the traffic to servers. The servers can then, for example, identify traffic belonging to a specific set for logging and monitoring purposes.

The source IP persistency option of a net profile enables the Citrix ADC appliance to use the same address, specified in the net profile, to communicate with servers about all sessions initiated from a specific client to a virtual server.

To enable source IP persistency in a net profile by using the CLI

To enable source IP persistency while adding a net profile, at the command prompt, type:

```
add netProfile <name> -srcippersistency ( ENABLED | DISABLED )

show netprofile <name>
```

To enable source IP persistency in an existing net profile, at the command prompt, type:

```
set netProfile <name> -srcippersistency ( ENABLED | DISABLED )

show netprofile <name>
```

To enable source IP persistency in a net profile by using the GUI

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Select **Source IP Persistency** while adding or modifying a net profile.

Example

In the following sample configuration, net profile NETPROFILE-IPPRSTNCY-1 has the source IP persistency option enabled and is bound to load balancing virtual server LBVS-1.

The Citrix ADC appliance always uses the same IP address (in this example, 192.0.2.11) to communicate with servers bound to LBVS-1, for all sessions initiated from a specific client to the virtual server.

```
```
> add ipset IPSET-1

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved. 
```

```
Done
> bind ipset IPSET-1 192.0.2.[11-15]
 IPAddress "192.0.2.11" bound
 IPAddress "192.0.2.12" bound
 IPAddress "192.0.2.13" bound
 IPAddress "192.0.2.14" bound
 IPAddress "192.0.2.15" bound
 Done
> add netprofile NETPROFILE-IPPRSTNCY-1 -srcIp IPSET-1 -
    srcippersistency ENABLED

Done
> set lb vserver LBVS-1 -netprofile NETPROFILE-IPPRSTNCY-1

 Done
```

Use IPv6 link local addresses on the server side of a load balancing setup

September 14, 2021

IPv6 link local address is supported for services, service groups, and servers of a load balancing configuration. You can specify a link local IPv6 address along with the associated VLAN ID in services, service groups, and servers configurations. The Citrix ADC appliance uses the link local SNIP6 address from the same VLAN as specified in the services, service groups, and servers configurations to communicate with them.

A link local IPv6 address and the associated VLAN ID are specified in the following format in services, service groups, and servers configurations: <IPv6_Addrs>%<vlan_id>

For example, fe80:123:4567::a%2048:, fe80:123:4567::a is the link local address AND 2048 is the VLAN ID.

```
> add service SERVICE-1 fe80:123:4567::a%2048 HTTP 80

Done
> bind servicegroup SERVICE-GROUP-1 fe80::1%24 80

Done
> add server SERVER-1 fe80:b:c:d::e:f:a/64%1028

Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Advanced load balancing settings

September 14, 2021

In addition to configuring virtual servers, you can configure advanced settings for services.

To configure advanced load balancing settings, see the following sections:

- Gradually step up the load on a new service with virtual server–level slow start
- The no-monitor option for services
- Protect applications on protected servers against traffic surges
- Enable cleanup of virtual server and service connections
- Graceful shutdown of services
- Enable or disable persistence session on TROFS services
- Direct requests to a custom webpage
- Enable access to services when down
- Enable TCP buffering of responses
- Enable compression
- Maintain client connection for multiple client requests
- Insert IP address of the client in the request header
- Retrieve location details from user IP address using geolocation database
- Use the source IP address of the client when connecting to the server
- Configure the source port for server-side connections
- Set a limit on the number of client connections
- Set a limit on the number of requests per connection to the server
- Set a threshold value for the monitors bound to a service
- Set a timeout value for idle client connections
- Set a timeout value for idle server connections
- Set a limit on the bandwidth usage by clients
- Redirect client requests to a cache
- Retain the VLAN identifier for VLAN transparency
- Configure automatic state transition based on percentage health of bound services

Gradually step up the load on a new service with virtual server–level slow start

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

You can configure the Citrix ADC appliance to gradually increase the load on a service (the number of requests that the service receives per second) immediately after the service is either added to a load balancing configuration or has a state change from DOWN to UP (in this document, the term ‘‘new service’’is used for both situations). You can either increase the load manually with load values and intervals of your choice (manual slow start) or configure the appliance to increase the load at a specified interval (automated slow start) until the service is receiving as many requests as the other services in the configuration. During the ramp-up period for the new service, the appliance uses the configured load balancing method.

This functionality is not available globally. It has to be configured for each virtual server. The functionality is available only for virtual servers that use one of the following load balancing methods:

- Round robin
- Least connection
- Least response time
- Least bandwidth
- Least packets
- LRTM (Least Response Time Method)
- Custom load

For this functionality, you need to set the following parameters:

- The new service request rate, which is the amount by which to increase the number or percentage of requests sent to a new service each time the rate is incremented. That is, you specify the size of the increment in terms of either the number of requests per second or the percentage of the load being borne, at the time, by the existing services. If this value is set to 0 (zero), slow start is not performed on new services.

  Note: In an automated slow start mode, the final increment is smaller than the specified value if the specified value would place a heavier load on the new service than on the other services.

- The increment interval, in seconds. If this value is set to 0 (zero), the load is not incremented automatically. You have to increment it manually.

With an automated slow start, a service is taken out of the slow start phase when one of the following conditions applies:

- The actual request rate is less than the new service request rate.
- The service does not receive traffic for three successive increment intervals.
- The request rate has been incremented 200 times.
- The percentage of traffic that the new service must receive is greater than or equal to 100.

With manual slow start, the service remains in the slow start phase until you take it out of that phase.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Manual slow start

If you want to manually increase the load on a new service, do not specify an increment interval for the load balancing virtual server. Specify only the new service request rate and the units. With no interval specified, the appliance does not increment the load periodically. It maintains the load on the new service at the value specified by the combination of the new service request rate and units until you manually modify either parameter. For example, if you set the new service request rate and unit parameters to 25 and "per second,"respectively, the appliance maintains the load on the new service at 25 requests per second until you change either parameter. When you want the new service to exit the slow start mode and receive as many requests as the existing services, set the new service request rate parameter to 0.

As an example, assume that you are using a virtual server to load balance 2 services, Service1 and Service2, in round robin mode. Further assume that the virtual server is receiving 240 requests per second, and that it is distributing the load evenly across the services. When a new service, Service3, is added to the configuration, you might want to increase the load on it manually through values of 10, 20, and 40 requests per second before sending it its full share of the load. The following table shows the values to which you set the three parameters.

Table 1. Parameter Values

Parameter	Value
Interval in seconds	0
New service request rate	10, 20, 40, and 0, at intervals that you choose
Units for the new service request rate	Requests per second

When you set the new service request rate parameter to 0, Service3 is no longer considered a new service, and receives its full share of the load.

Assume that you add another service, Service4, during the ramp-up period for Service3. In this example, Service4 is added when the new service request rate parameter is set to 40. Therefore, Service4 begins receiving 40 requests per second.

The following table shows the load distribution on the services during the period described in this example.

Table 2. Load Distribution on Services when Manually Stepping Up the Load

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

	new service request rate = 10 req/sec (Service3added)	new service request rate = 20 req/sec	new service request rate = 40 req/sec (Service4added)	new service request rate = 0 req/sec (new services exit slow start mode)
Service1	115	110	80	60
Service2	115	110	80	60
Service3	10	20	40	60
Service4	-	-	40	60
Total req/sec (load on the virtual server)	240	240	240	240

Automated slow start

If you want the appliance to increase the load on a new service automatically at specified intervals until the service can be considered capable of handling its full share of the load, set the new service request rate parameter, the units parameter, and the increment interval. When all the parameters are set to values other than 0, the appliance increments the load on a new service by the value of the new service request rate, at the specified interval, until the service is receiving its full share of the load.

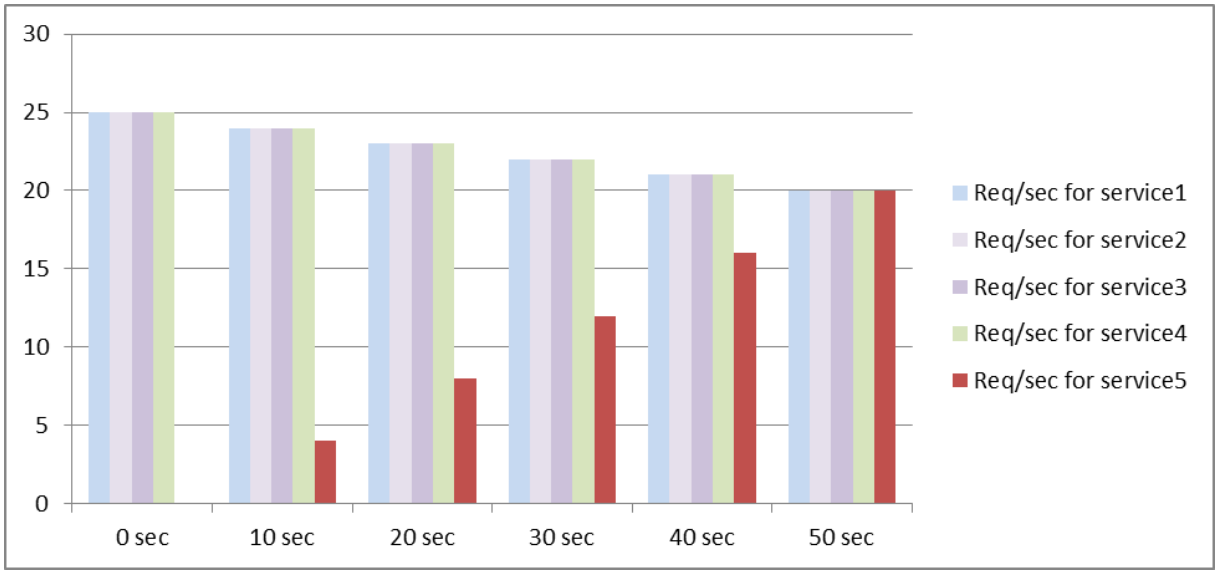
As an example, assume that four services, Service1, Service2, Service3, and Service4, are bound to a load balancing virtual server, vserver1. Further assume that vserver1 receives 100 requests per second, and that it distributes the load evenly across the services (25 requests per second per service). When you add a fifth service, Service5, to the configuration, you might want the appliance to send the new service 4 requests per second for the first 10 seconds, 8 requests per second for the next 10 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters:

Table 3. Parameter Values

Parameter	**Value**
Interval in seconds	10
Increment value	4
Units for the new service request rate	Requests per second

With this configuration, the new service begins receiving as many requests as the existing services 50

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



seconds after it is added or its state has changed from DOWN to UP. During each interval in this period, the appliance distributes to the existing servers the excess of requests that would have been sent to the new service in the absence of stepwise increments. For example, in the absence of stepwise increments, each service, including Service5, would have received 20 requests each per second. With stepwise increments, during the first 10 seconds, when Service5 receives only 4 requests per second, the appliance distributes the excess of 16 requests per second to the existing services, resulting in the distribution pattern shown in the following table and figure over the 50-second period. After the 50-second period, Service5 is no longer considered a new service, and it receives its normal share of traffic.

Table 4. Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

	0 sec	10 sec	20 sec	30 sec	40 sec	50 sec
Req/sec forService1	25	24	23	22	21	20
Req/sec forService2	25	24	23	22	21	20
Req/sec forService3	25	24	23	22	21	20
Req/sec forService4	25	24	23	22	21	20
Req/sec forService5	0	4	8	12	16	20
Total req/sec (load on the virtual server)	100	100	100	100	100	100

Figure 1. A Graph of the Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

An alternative requirement might be for the appliance to send Service5 25% of the load on the existing services in the first 5 seconds, 50% in the next 5 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters.

Table 5. Parameter Values

Parameter	Value
Interval in seconds	5
Increment value	25
Units for the new service request rate	Percent

With this configuration, the service begins receiving as many requests as the existing services 20 seconds after it is added or its state has changed from DOWN to UP. The traffic distribution during the ramp-up period for the new service is identical to the one described earlier, where the unit for the step increments was "requests per second."

Set the slow start parameters

You set the slow start parameters by using either the `set lb vserver` or the `add lb vserver` command. The following command is for setting slow start parameters when adding a virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure stepwise load increments for a new service by using the command line interface

At the command prompt, type the following commands to configure stepwise increments in the load for a service and verify the configuration:

```
add lb vserver <name> <serviceType> <IPAddress> <port> [-
   newServiceRequest <positive_integer>] [<newServiceRequestUnit>] [-
   newServiceRequestIncrementInterval <positive_integer>]

show lb vserver <name>
```

Example

```
set lb vserver BR_LB -newServiceRequest 5 PER_SECOND -
   newServiceRequestIncrementInterval 10
Done

show lb vserver BR_LB
BR_LB (192.0.2.33:80) - HTTP Type: ADDRESS
State: UP
...
...
New Service Startup Request Rate: 5 PER_SECOND, Increment Interval: 10
...
...
Done
```

To configure stepwise load increments for a new service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select Method, and set the following slow start parameters:
   - New Service Startup Request Rate.
   - New Service Request Unit.
   - Increment Interval.

The no-monitor option for services

September 14, 2021

If you use an external system to perform health checks on the services and do not want the Citrix ADC appliance to monitor the health of a service, you can set the no-monitor option for the service. If you do so, the appliance does not send probes to check the health of the service but shows the service as UP. Even if the service goes DOWN, the appliance continues to send traffic from the client to the service as specified by the load balancing method.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The monitor can be in the ENABLED or DISABLED state when you set the no-monitor option, and when you remove the no-monitor option, the earlier state of the monitor is resumed.

You can set the no-monitor option for a service when creating the service. You can also set the no-monitor option on an existing service.

The following are the consequences of setting the no-monitor option:

- If a service for which you enabled the no-monitor option goes down, the appliance continues to show the service as UP and continues to forward traffic to the service. A persistent connection to the service can worsen the situation. In that case, or if many services shown as UP are actually DOWN, the system may fail. To avoid such a situation, when the external mechanism that monitors the services reports a service as DOWN, remove the service from the Citrix ADC configuration.
- If you configure the no-monitor option on a service, you cannot configure load balancing in the Direct Server Return (DSR) mode. For an existing service, if you set the no-monitor option, you cannot configure the DSR mode for the service.

To set the no-monitor option for a new service by using the CLI

At the command prompt, type the following commands to create a service with the health monitor option, and verify the configuration:

```
add service <serviceName> <IP | serverName> <serviceType> <port> -
   healthMonitor (YES|NO)
```

Example:

```
add service nomonsrvc 10.102.21.21 http 80 -healthMonitor no
Done

show service nomonsrvc
nomonsrvc (10.102.21.21:80) - HTTP
State: UP
Last state change was at Mon Nov 15 22:41:29 2010
Time since last state change: 0 days, 00:00:00.970
Server Name: 10.102.21.21
 Server ID : 0 Monitor Threshold : 0
...
Access Down Service: NO
...
Down state flush: ENABLED
Health monitoring: OFF

1 bound monitor:
1) Monitor Name: tcp-default
State: UNKNOWN Weight: 1
Probes: 3 Failed [Total: 3 Current: 3]
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
Last response: Probe skipped - Health monitoring is turned off.
Response Time: N/A
Done
```

To set the no-monitor option for an existing service by using the CLI

At the command prompt, type the following command to set the health monitor option:

```
set service <name> -healthMonitor (YES|NO)
```

Example:

```
By default, the state of a service and the state of the corresponding
   monitor are UP.
 >show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP

1) Monitor Name: http-ecv
 State: UP Weight: 1
Probes: 99992 Failed [Total: 0 Current: 0]
Last response: Success - Pattern found in response.
Response Time: 3.76 millisec
Done

When the no-monitor option is set on a service, the state of the
   monitor changes to UNKNOWN.
set service LB-SVC1 -healthMonitor NO
Done

show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
Last state change was at Fri Dec 10 10:17:37 2010.
Time since last state change: 5 days, 18:55:48.710
Health monitoring: OFF

1) Monitor Name: http-ecv
   State: UNKNOWN Weight: 1
         Probes: 100028 Failed [Total: 0 Current: 0]
   Last response: Probe skipped - Health monitoring is turned off.
     Response Time: 0.0 millisec
  Done
When the no-monitor option is removed, the earlier state of the monitor
    is resumed.
> set service LB-SVC1 -healthMonitor YES
Done
>show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
```

```
Last state change was at Fri Dec 10 10:17:37 2010
Time since last state change: 5 days, 18:57:47.880
1) Monitor Name: http-ecv
   State: UP Weight: 1
   Probes: 100029 Failed [Total: 0 Current: 0]
   Last response: Success - Pattern found in response.
   Response Time: 5.690 millisec
   Done
```

To set the no-monitor option for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and clear Health Monitoring.

Protect applications on protected servers against traffic surges

September 14, 2021

The Citrix ADC appliance provides the surge protection option to maintain the capacity of a server or cache. The appliance regulates the flow of client requests to servers and controls the number of clients that can simultaneously access the servers. The appliance blocks any surges passed to the server, thus preventing overloading of the server.

For surge protection to function correctly, you must enable it globally. For more information about surge protection, see Surge Protection.

To set surge protection on the service by using the CLI

At the command prompt, type:

```
set service <name> -sp <Value>
```

Example:

```
set service Service-HTTP-1 -sp ON
```

To set surge protection on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a source.
2. In Advanced Settings, select **Traffic Settings**, and select **Surge Protection**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Enable cleanup of virtual server and service connections

September 14, 2021

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes or health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN. If a service or virtual server is marked DOWN, the server and client side connections must be flushed. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

Under certain conditions, you can configure the **downStateFlush** setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Do not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with one service bound to it, Service-1. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

Vserver-LB-1	Service-1	State of Connections
E	E	Both client and server connections are terminated.
E	D	For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Vserver-LB-1	Service-1	State of Connections
D	E	For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated.
D	D	Neither client nor server connections are terminated.

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see Graceful Shutdown of Services.

To set down state flush on the service by using the CLI

At the command prompt, type:

```
set service <name>  -downStateFlush (ENABLED | DISABLED )
```

Example:

```
set service Service-HTTP-1 -downStateFlush enabled
```

To set down state flush on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Down State Flush**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set down state flush on the virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name>  -downStateFlush (ENABLED | DISABLED )
```

Example:

```
set lb vserver vsvr1 -downStateFlush enabled
```

To set down state flush on the virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and select **Down State Flush**.

Graceful shutdown of services

September 14, 2021

During scheduled network outages such as system upgrades or hardware maintenance, you may have to close or disable some services. You can later enable the service by using the "enable service <name > command.

To avoid disrupting established sessions, you can place a service in the Transition Out of Service (TROFS) state by doing one of the following:

- Adding a TROFS code or string to the monitor—Configure the server to send a specific code or string in response to a monitor probe.
- Explicitly disable the service and:
  - Set a delay (in seconds).
  - Enable graceful shutdown.

Adding a TROFS Code or String

If you bind only one monitor to a service, and the monitor is TROFS-enabled, it can place the service in the TROFS state on the basis of the server's response to a monitor probe. This response is compared with the value in the trofsCode parameter for an HTTP monitor or the trofsString parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the persistent connections.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If multiple monitors are bound to a service, the effective state of the service is calculated on the basis of the state of all the monitors that are bound to the service. Upon receiving a TROFS response, the state of the TROFS-enabled monitor is considered as UP for the purpose of this calculation. For more information about how a Citrix ADC appliance designates a service as UP, see Setting a Threshold Value for the Monitors Bound to a Service.

Important:

- You can bind multiple monitors to a service, but must not TROFS-enable more than one of them.
- You can convert a TROFS-enabled monitor to a monitor that is not TROFS-enabled, but not vice versa.

To configure a TROFS code or string in a monitor by using the command line interface

At the command prompt, type one of the following commands:

```
add lb monitor <monitor-name> HTTP -trofsCode <respcode>

add lb monitor <monitor-name> HTTP-ECV  -trofsString <resp string>

add lb monitor <monitor-name> TCP-ECV  -trofsString <resp string>
```

To modify the TROFS code or string by using the command line interface

At the command prompt, type one of the following commands:

```
set lb monitor <trofs monitorname> HTTP -trofscode <newcode>

set lb monitor <trofs monitorname> HTTP-ECV -trofsstring <new string>

set lb monitor <trofs monitorname> TCP-ECV -trofsstring <new string>
```

Note: You can use the set command only if a TROFS-enabled monitor was added earlier. You cannot use this command to set the TROFS code or string for a monitor that is not TROFS-enabled.

To configure a TROFS code or string in a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, click Add, and do one of the following:
    - Select Type as HTTP, and specify a TROFS Code.
    - Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Disabling a Service

Often, however, you cannot estimate the amount of time needed for all the connections to a service to complete the existing transactions. If a transaction is unfinished when the wait time expires, shutting down the service may result in data loss. In this case, you can specify graceful shutdown for the service, so that the service is disabled only when all the current active client connections are closed by either the server or the client. See the following table for behavior if you specify a wait time in addition to graceful shutdown.

Persistence is maintained according to the specified method even if you enable graceful shutdown. The system continues to serve all the persistent clients, including new connections from the clients, unless the service is marked DOWN during the graceful shutdown state as a result of the checks made by a monitor.

The following table describes the graceful shutdown options.

State	Results
Graceful shutdown is enabled and a wait time is specified.	Service is shut down after the last of the current active client connections is served, even if the wait time has not expired. The appliance checks the status of the connections once every second. If the wait time expires, any open sessions are closed.
Graceful shutdown is disabled and a wait time is specified.	Service is shut down only after the wait time expires, even if all established connections are served before expiration.
Graceful shutdown is enabled and no wait time is specified.	Service is shut down only after the last of the previously established connections is served, regardless of the time taken to serve the last connection.
Graceful shutdown is disabled and no wait time is specified.	No graceful shutdown. Service is shut down immediately after the disable option is chosen or the disable command is issued. (The default wait time is zero seconds.)

To terminate existing connections when a service or a virtual server is marked DOWN, you can use the Down State Flush option. For more information, see Enabling Cleanup of Virtual Server Connections.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure graceful shutdown for a service by using the command line interface

At the command prompt, type the following commands to shut down a service gracefully and verify the configuration:

```
disable service <name> [<delay>] [-graceFul (YES|NO)]

show service <name>
```

Example:

```
> disable service svc1 6000 -graceFul YES
Done
>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: GOING OUT OF SERVICE (Graceful, Out Of Service in 5998 seconds)
Last state change was at Mon Nov 15 22:44:15 2010
Time since last state change: 0 days, 00:00:01.160
...
Down state flush: ENABLED

1 bound monitor:
1) Monitor Name: tcp-default
State: UP              Weight: 1
Probes: 13898    Failed [Total: 0 Current: 0]
Last response: Probe skipped - live traffic to service.
Response Time: N/A
Done

>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: OUT OF SERVICE
Last state change was at Mon Nov 15 22:44:19 2010
Time since last state change: 0 days, 00:00:03.250
Down state flush: ENABLED

1 bound monitor:
1)  Monitor Name: tcp-default
State: UNKNOWN           Weight: 1
Probes: 13898    Failed [Total: 0 Current: 0]
Last response: Probe skipped - service state OFS.
Response Time: N/A
Done
```

To configure graceful shutdown for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and from the Action list, click Disable. Enter a wait time, and select Graceful.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Enable or disable persistence session on TROFS services

September 14, 2021

You can set the trofsPersistence flag to specify whether a service in the transition out of service (TROFS) state must maintain persistent sessions. When a monitor is TROFS enabled, it can place a service in the TROFS state on the basis of the server's response to a monitor probe. This response is compared with the value in the trofsCode parameter for an HTTP monitor or the trofsString parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the active client connections. In some cases, the honored active sessions might have to include persistent sessions. But in other cases, especially those involving long-lived persistence sessions or persistence methods such as custom server ID, honoring the persistent sessions can prevent the service from transitioning to the out-of-service state.

If you set the trofsPersistence flag to ENABLED, persistent sessions are honored. If you set it to DISABLED, they are not.

To set the trofsPersistence flag by using the command line interface

At the command prompt, type one of the following commands to set the `trofsPersistence` flag for a new virtual server or an existing virtual server, or to return the setting to its default value:

```
add lb vserver <name> [-trofsPersistence ( ENABLED | DISABLED )]

set lb vserver <name> [-trofsPersistence ( ENABLED | DISABLED )]

unset lb vserver <name> [-trofsPersistence]
```

Argument

trofsPersistence. Honor current active client connections and new requests on persistence sessions when the service is in TROFS state.

Possible values: ENABLED, DISABLED. Default: ENABLED.

Examples:

```
add lb vserver v1 http 10.102.217.42 80 -persistencetype SOURCEIP –
    trofsPersistence ENABLED

set lb vserver v1 -trofsPersistence DISABLED

unset lb vserver v1 -trofsPersistence
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Direct requests to a custom webpage

September 14, 2021

> **Warning**
>
> SureConnect (SC) is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. For more information, see AppQoE.

For SureConnect to function correctly, you must set it globally. The Citrix ADC provides the SureConnect option to ensure the response from an application.
For more information about the SureConnect option, see Sure Connect.

To set SureConnect on the service by using the CLI

At the command prompt, type:

```
set service <name> -sc <Value>
```

Example:

```
set service Service-HTTP-1 -sc ON
```

To set SureConnect on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select Traffic Settings, and select **Sure Connect**.

Enable access to services when down

September 14, 2021

You can enable access to a service when it is disabled or in a DOWN state by configuring the Citrix ADC appliance to use Layer 2 mode to bridge the packets sent to the service. Normally, when requests are forwarded to services that are DOWN, the request packets are dropped. When you enable the **Access Down** setting, however, these request packets are sent directly to the load balanced servers.

For more information about Layer 2 and Layer 3 modes, see IP Addressing.

For the appliance to bridge packets sent to the DOWN services, enable Layer 2 mode with the accessDown parameter.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable access down on a service by using the CLI

At the command prompt, type:

```
set service <name> -accessDown <Value>
```

Example:

```
set service Service-HTTP-1 -accessDown YES
```

To enable access down on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Access Down**.

Enable TCP buffering of responses

September 14, 2021

The Citrix ADC appliance provides a TCP buffering option that buffers only responses from the load balanced server. This enables the appliance to deliver server responses to the client at the maximum speed that the client can accept them. The appliance allocates from 0 through 4095 MB (MB) of memory for TCP buffering, and from 4 through 20480 kilobytes (KB) of memory per connection.

Note: TCP buffering set at the service level takes precedence over the global setting.
For more information about configuring TCP buffering globally, see TCP Buffering.

To enable TCP Buffering on a service by using the CLI

At the command prompt, type:

```
set service <name> -TCPB <Value>
```

Example:

```
set service Service-HTTP-1 -TCPB YES
```

To enable TCP Buffering on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **TCP Buffering**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Enable compression

September 14, 2021

The Citrix ADC appliance provides a compression option to transparently compress HTML and text files by using a set of built-in compression policies. Compression reduces bandwidth requirements and can significantly improve server responsiveness in bandwidth-constrained setups. The compression policies are associated with services bound to the virtual server. The policies determine whether a response can be compressed and send compressible content to the appliance, which compresses it and sends it to the client.

Note: For compression to function correctly, you must enable it globally. For more information about configuring compression globally, see Compression.

To enable compression on a service by using the CLI

At the command prompt, type:

```
set service <name> -CMP <YES | NO>
```

Example:

```
set service Service-HTTP-1 -CMP YES
```

To enable compression on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Compression**.

Enable external TCP health check for UDP virtual servers

September 14, 2021

In public clouds, you can use the Citrix ADC appliance as a second-tier load balancer when the native load balancer is used as a first tier. The native load balancer can be an application load balancer (ALB) or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. To monitor the health of the UDP application, public clouds recommend adding a TCP-based endpoint to your service. The endpoint reflects the health of the UDP application.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The Citrix ADC appliance supports the external TCP-based health check for a UDP virtual server. This feature introduces a TCP listener on the VIP of the virtual server and the configured port. The TCP listener reflects the status of the virtual server.

To enable an external TCP health check for UDP virtual servers by CLI

At the command prompt, type the following command to enable an external TCP health check with the tcpProbePort option:

```
add lb vserver <name> <serviceType> <IPAddress> <port> -tcpProbePort <
   tcpProbePort>
```

Example:

```
add lb vserver Vserver-UDP-1 UDP 10.102.29.60 80 tcpProbePort 5000
```

To enable an external TCP health check for UDP virtual servers by GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and then create a virtual server.
2. Click **Add** to create a virtual server.
3. In the **Basic Settings** pane, add the port number in the **TCP Probe Port** field.
4. Click **OK**.

Maintain client connection for multiple client requests

September 14, 2021

You can set the client keep-alive parameter to configure an HTTP or SSL service to keep a client connection to a website open across multiple client requests. If client keep-alive is enabled, even when the load balanced Web server closes a connection, the Citrix ADC appliance keeps the connection between the client and itself open. This setting allows services to serve multiple client requests on a single client connection.

If you do not enable this setting, the client opens a new connection for every request that it sends to the website. The client keep-alive setting saves the packet round trip time required to establish and close connections. This setting also reduces the time to complete each transaction. Client keep-alive can be enabled only on HTTP or SSL service types.

Client keep-alive set at the service level takes precedence over the global client keep-alive setting. For more information about client keep-alive, see Client Keep-Alive.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable the client keep-alive on a service by using the CLI

At the command prompt, type:

```
set service <name> -CKA <Value>
```

Example:

```
set service Service-HTTP-1 -CKA YES
```

To enable the client keep-alive on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Client Keep-Alive**.

Insert the IP address of the client in the request header

September 14, 2021

A Citrix ADC uses the subnet IP (SNIP) address to connect to the server. The server need not be aware of the client.

However, in some situations, the server needs to be aware of the client it has to serve. When you enable the client IP setting, the appliance inserts the client's IPv4 or IPv6 address while forwarding the requests to the server. The server inserts this client IP in the header of the responses. The server is thus aware of the client.

> **Note**: To insert multiple headers, you need to perform one of the following:
>
> - Add rewrite policies to check CLIENT.IS_SSL and insert appropriate header.
> - Bind the appropriate rewrite policy for each virtual server based on the type.

To insert the client IP address in the client request by using the CLI

At the command prompt, type:

```
set service <name> -CIP <Value> <cipHeader>
```

Example:

```
set service Service-HTTP-1 -CIP enabled X-Forwarded-For
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To insert the client IP address in the client request by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**, and edit a service.
2. In the **Service Settings** pane, click the **edit icon**.
3. In the **Load Balancing Service** pane, select the **Insert Client IP Address** check box.

Retrieve location details from user IP address using geolocation database

September 14, 2021

> **Note** This feature is available from Citrix ADC release 12.1 build 50.x and later.

The Citrix ADC appliance can get user location details like continent, county, and city. For any public IP address from a geo location database. It is performed using the advanced policy infrastructure. The retrieved location details are then used in a rewrite action or a responder action for performing the following use cases.

- Insert an HTTP header with user location details (such as country, city information) when sending the client request to the back-end server.
- Add country name in the HTML page response for an invalid user.

The appliance can also log the location details using the audit logging mechanism.

Getting user location details using geolocation functions

The components interact as per the following:

1. User sends a client request from a particular geographic location.
2. The Citrix ADC appliance looks for the user IP address from the client request and retrieves the geo location details. The details include continent, country, region, city, ISP, organization, or custom details from a geolocation database.
3. Once the location details are retrieved, the appliance uses either a responder policy or a rewrite policy to evaluate the request.
4. In a rewrite policy, the appliance adds a header with the geo location details and sends it to the back-end server. For example, insert a custom HTTP header with country information.
5. In a responder policy, the appliance evaluates the HTTP request and based on policy evaluation, allows access to the users or redirects the user to an error page. It states the region from where they are accessing the application does not have access.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Setting up geolocation database

As a pre-requisite, you must have a geolocation database to run on the Citrix ADC appliance. The geolocation database files are available with Citrix ADC firmware. To download the database files from a vendor, convert it into Citrix ADC format and import it into your appliance.
For more information about the geolocation database, see Add a location file to create static proximity database topic.

Geolocation functions

The following table gives a list of geolocation functions that retrieves location details of any public IP address. These functions can be used in rewrite or responder policies.

Geolocation function	Example
CLIENT.IP.SRC.LOCATION	Asia.In.Karnataka.Bangalore
CLIENT.IP.SRC.LOCATION.GET (1).LOCATION_LONG	India
CLIENT.IP.SRC.LOCATION(3)	Asia.In.Karnataka
CLIENT.IP.SRC.LAT_LONG	12,77
CLIENT.IPV6.SRC.LOCATION	North America.US.California.Santa Clara.Verizon.Citrix
CLIENT.IPV6.SRC.LOCATION(3)	North America.US.California
CLIENT.IPV6.SRC.LOCATION.GET(1).LOCATION_LONG	United States
CLIENT.IPV6.SRC.LOCATION.GET(3)	California
CLIENT.IPV6.SRC.LAT_LONG	36, -119

Configuring geolocation functions

To configure geolocation functions using advanced policy infrastructure, you must enable the load balancing, rewrite, and responder features and then complete the following use cases.

Enable load balancing, responder, rewrite features

If you want the Citrix ADC appliance to authorize user access from a particular geo location, you must enable the load balancing, rewrite, and responder features.

```
1 enable ns feature loadbalancing rewrite responder
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Use case 1: Configuring geolocation function for redirecting invalid users outside geo location

When a user from India is requesting access to a webpage, block the request and respond with an HTML page with country name.

The following steps help you to complete the configuration of this use case.

- Add responder action
- Add responder policy
- Bind responder policy to load balancing server

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see Responder topic

Add responder action Add a responder action to respond with HTML page with country name.
At the command prompt, type:

```
add responder action <name> <type> (<target> | <htmlpage>) [-comment <
    string>] [-responseStatusCode <positive_integer>][-reasonPhrase <
    string>]
```

Example:

```
add responder action responder_act respondwith "HTTP.REQ.VERSION + \"
    304 Requested Page not allowed in your country - \" + CLIENT.IP.SRC.
    LOCATION.GET (1).LOCATION_LONG + \"\r\n\""
```

Add audit log message action You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats. Audit-message actions use expressions to specify the format of the audit messages.
To create an audit message action by using the command line interface

At the command prompt, type:
`add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewnslog (YES|NO)] [-bypassSafetyCheck (YES|NO)]`

Example:

```
add audit messageaction msg1 DEBUG "\"Request Location: \"+CLIENT.IP.
    SRC.LOCATION"
```

Add responder policy Add a responder policy to identify requests coming from India and associate the responder action to this policy.
At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add responder policy <name> <rule> <action> [<undefAction>] [-comment <
    string>] [-logAction <string>] [-appflowAction <string>]
```

Example:

```
add responder policy responder_pol CLIENT.IP.SRC.MATCHES_LOCATION("Asia
    .India.*.*.*.*") responder_act -logaction msg1
```

Bind responder policy to load balancing server Bind the responder policy to a load balancing virtual server of type HTTP/SSL.
At the command prompt, type:

```
bind lb vserver <vserver name> -policyName < policy_name >  -priority
    <> -type <L7InlineREQUEST | L4Inline-REQUEST>
```

Example:

```
bind lb vserver http_vserver -policyName responder_pol -priority 100 -
    type REQUEST
```

Use case 2: Configuring geolocation function for inserting new HTTP header with location details for back-end to respond

Consider a scenario, where a Citrix ADC appliance must insert the user location in the HTTP header of a request sent to the application server so that the server can use the information for some business logic.
The following steps help you to complete the configuration of this use case.

- Add rewrite action
- Add rewrite policy
- Bind rewrite policy to load balancing

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see Responder topic.

Add rewrite action Add a rewrite action to insert a custom HTTP header with user geolocation details in the request and send it back-end servers.
At the command prompt, type:

```
add rewrite action <name> <type> <target> [<stringBuilderExpr>] [-
    pattern <expression> | -search <expression>] [-refineSearch <string
    >][-comment <string>]
```

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add rewrite action rewrite_act insert_http_header "User_location"
    CLIENT.IP.SRC.LOCATION
```

Add rewrite policy Add a rewrite policy to evaluate if the rewrite action must be run. In this case, all requests going to the application server must have a custom HTTP header, so the rule can be "true."
At the command prompt, type:

```
add rewrite policy <name> <rule> <action> [<undefAction>] [-comment <
    string>] [-logAction <string>]
```

Example:

```
add rewrite policy rewrite_pol true rewrite_act -logaction log_act
```

Bind rewrite policy to load balancing Bind the rewrite policy to the required load balancing virtual server of type HTTP/SSL.
At the command prompt, type:

```
bind lb vserver <vserver name> -policyName < policy_name >  -priority
    <> -type <L7InlineREQUEST | L4Inline-REQUEST>
```

Example:

```
bind lb vserver http_vserver -policyName rewrite_pol -priority 100 -
    type REQUEST
```

Syslog support for logging geolocation details (optional)

If you prefer to log the user's geolocation details, you must specify the SYSLOG action to be performed when a request matches the policy. The appliance stores the details as a log message in the ns.log file. For more information about SYSLOG and NSLOG auditing, see Audit logging topic.

Output for user geolocation details

The following output is logged in the appliance using the SYSLOG or `newnslog` action if you try to access an application from the Bangalore location and if the appliance uses the geolocation function, "CLIENT.IP.SRC.LOCATION'.

```
Asia.India.Karnataka.Banglore
```

Sample output log:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
07/23/2018:19:03:54 GMT  Debug 0-PPE-0 : default REWRITE Message 22 0 :
     "Request Location: asia.in.karnataka.bangalore.*.*"
07/23/2018:19:23:55 GMT  Debug 0-PPE-0 : default RESPONDER Message 32 0
Done
```

Use the source IP address of the client when connecting to the server

September 14, 2021

You can configure the Citrix ADC appliance to forward packets from the client to the server without changing the source IP address. This is useful when you cannot insert the client IP address into a header, such as when working with non-HTTP services.

For more information about configuring USIP globally, see Enabling Use Source IP Mode.

To enable USIP mode for a service by using the CLI

At the command prompt, type:

```
set service <name> -usip (YES | NO)
```

Example:

```
set service Service-HTTP-1 -usip YES
```

To enable USIP mode for a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**, and open a service.
2. In Advanced Settings, in the Service Settings section, select **Use Source IP Address**.

Use client source IP address for back end communication in a v4-v6 load balancing configuration

September 14, 2021

In a v4-to-v6 load balancing configuration, for services with USIP disabled, the Citrix ADC appliance communicates to the related servers from one of the configured IPv6 SNIP (SNIP6) addresses.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For services with USIP enabled, you must set the global USIP NAT prefix parameter for making the related servers aware of the client's IP address of the request packets. USIP NAT prefix is a global IPv6 prefix of length 32/40/48/56/64/96 bits configured on the Citrix ADC appliance.

For a load balancing service that has USIP enabled, the appliance translates the IPv4 request packet to an IPv6 packet and sets the source IP address of the translated IPv6 packet to a concatenation of:

- the USIP NAT prefix of length of 32/40/48/56/64/96 bits.
- zeros padded if the USIP NAT prefix length is less than 96 bits. Number of bits padded with zeros = 96-USIP NAT prefix length. For example, if the USIP NAT prefix length is 64, then the number of bits padded with zeros = 96-64 = 32.
- the IPv4 source address [32 bits] that was received in the request packet. In other words, the last 32 bits of the source IPv6 address is set to the IPv4 address of the client.

On receiving an IPv6 response packet from the server, the Citrix ADC appliance translates the IPv6 packet to an IPv4 packet and sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

> **Note**: This feature is not supported for Citrix Gateway configuration and, content switching and cache redirection load balancing configurations.

Configuration Steps

Configuring USIP for a v4-to-v6 load balancing configuration consists of the following tasks:

- **Add global USIP NAT prefix**. It is a global IPv6 prefix of length 32/40/48/56/64/96 bits to be configured on the appliance.
- **Enable global USIP mode**. For more information, see Enable Use Source IP Mode.
- **Enable USIP mode for load balancing services**. For more information, see Use source IP address of the client when connecting to the server.

To add a global USIP NAT prefix by using the CLI:

- `set ipv6 -usipnatprefix <prefix/prefix_length>`
- `show ipv6`

To add a global USIP NAT prefix by using the GUI:

1. Navigate to **System** > **Network**, and click **Change IPv6 Settings**.
2. On the **Configure Configuration for IPV6** screen, set the **USIP NAT Prefix** parameter.

Sample configuration

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> set ipv6 -usipnatprefix 2001:DB8:90::/64
Done

> enable ns mode USIP
Done

> add lb vserver LBVS-1 HTTP 203.0.113.90 80
Done

> add service SVC-1 2001:DB8:5001::30 HTTP 80 -usip yes
Done

> add service SVC-2 2001:DB8:5001::60 HTTP 80 -usip yes
Done

> bind lb vserver LBVS-1 SVC-1
Done

> bind lb vserver LBVS-1 SVC-2
Done
```

Configure the source port for server-side connections

September 14, 2021

When the Citrix ADC appliance connects to a physical server, it can use the source port from the client's request, or it can use a proxy port as the source port for the connection. You can set the Use Proxy Port parameter to YES to handle situations such as the following scenario:

- The Citrix ADC appliance is configured with two load balancing virtual servers, LBVS1 and LBVS2.
- Both the virtual servers are bound to the same service, S-ANY.
- Use (the client's) source IP address (USIP) is enabled on the service.
- Client C1 sends two requests, Req1 and Req2, for the same service.
- LBVS1 receives Req1 and LBVS2 receives Req2.
- LBVS1 and LBVS2 forward the request to S-ANY, and when S-ANY sends the response, LBVS1 and LBVS2 forward the response to the client.
- Consider two cases:
  - Use the client port. When the appliance uses the client port, both the virtual servers use the client's IP address (because USIP is ON) and the client's port when connecting to the server. Therefore, when the service sends the response, the appliance cannot determine which virtual server must receive the response.
  - Use proxy port. When the appliance uses a proxy port, the virtual servers use the client's IP address (because USIP is ON), but different ports when connecting to the server. Therefore,

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

when the service sends the response, the port number identifies the virtual server that must receive the response.

However, if you require a fully transparent configuration, such as a fully transparent cache redirection configuration, you must disable the Use Proxy port Setting so that the Citrix ADC appliance can use the source port from the client's request.

The Use Proxy Port option becomes relevant if the use source IP (USIP) option is enabled. For TCP-based service types, such as TCP, HTTP, and SSL, the option is enabled by default. For UDP-based service types, such as UDP and DNS, including ANY, the option is disabled by default. For more information about the USIP option, see "Enabling Use Source IP Mode."

You can configure the **Use Proxy Port** setting either globally or on a given service.

Configure the use proxy port setting on a service

You configure the **Use ProxyPort** setting on the service if you want to override the global setting.

To configure the Use Proxy Port setting on a service by using the CLI

At the command prompt, type:

```
set service <name> -useProxyPort (YES | NO)
```

Example:

```
set service svc1 -useproxyport YES
Done

show service svc1
svc1 (10.102.29.30:80) - HTTP
State: UP
. . .
Use Source IP: YES Use Proxy Port: YES
. . .
Done
```

To configure the Use Proxy Port setting on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select Traffic Settings, and select **Use Proxy Port**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure the use proxy port setting globally

You configure the **Use Proxy Port** setting globally if you want to apply the setting to all the services on the Citrix ADC appliance. The service-specific **Use Proxy Port** settings overrides the global setting.

To configure the Use Proxy Port setting globally by using the CLI

At the command prompt, type the following commands to configure the **Use Proxy Port** setting globally and verify the configuration:

```
set ns param -useproxyport ( ENABLED | DISABLED )`
show ns param`
```

Example:

```
set ns param -useproxyport ENABLED

Done

show ns param
Global configuration settings:
. . .
Use Proxy Port: ENABLED
Done
```

To configure the Use Proxy Port setting globally by using the GUI

Navigate to **System > Settings > Change global system** settings, and select or clear Use Proxy Port.

Set a limit on the number of client connections

September 14, 2021

You can specify a maximum number of client connections that each load balanced server can handle. The Citrix ADC appliance then opens client connections to a server only until this limit is reached. When the load balanced server reaches its limit, monitor probes are skipped, and the server is not used for load balancing until it has finished processing existing connections and frees up capacity.

For more information on the **Maximum Client** setting, see Load Balancing Domain-Name Based Services.

Note: Connections that are in the process of closing are not considered for this limit.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set a limit to the number of client connections by using the CLI

At the command prompt, type:

```
set service <name> -maxclient <Value>
```

Example:

```
set service Service-HTTP-1 -maxClient 1000
```

To set a limit to the number of client connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Clients**.

Set a limit on the number of requests per connection to the server

September 14, 2021

The Citrix ADC appliance can be configured to reuse connections to improve performance. In some scenarios, however, load balanced Web servers might have issues when connections are reused for too many requests. For HTTP or SSL services, use the max request option to limit the number of requests sent through a single connection to a load balanced Web server.

Note: You can configure the max request option for HTTP or SSL services only.

To limit the number of client requests per connection by using the CLI

At the command prompt, type:

```
set service <ServiceName> -maxReq <Value>
```

Example:

```
set service Service-HTTP-1 -maxReq 100
```

To limit the number of client requests per connection by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Requests**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Set a threshold value for the monitors bound to a service

September 14, 2021

The Citrix ADC appliance designates a service as UP only when the sum of the weights of all monitors bound to it and that are UP is equal to or greater than the threshold value configured on the service. The weight for a monitor specifies how much that monitor contributes to designating the service to which it is bound as UP.

By default, the monitor threshold is set to 0 and monitor weights are set to 1. All monitors have equal weightage then and a service can go DOWN when any one of the monitors goes DOWN.

For example, assume that three monitors, named Monitor-HTTP-1, Monitor-HTTP-2, and Monitor-HTTP-3 respectively, are bound to Service-HTTP-1, and that the threshold configured on the service is three. Suppose the following weights are assigned to each monitor:

- The weight of Monitor-HTTP-1 is 1.
- The weight of Monitor-HTTP-2 is 3.
- The weight of Monitor-HTTP-3 is 1.

The service is marked UP only when one of the following is true:

- Monitor-HTTP-2 is UP.
- Monitor-HTTP-2 and Monitor-HTTP-1 or Monitor-HTTP-3 are UP
- All three monitors are UP.

To set the monitor threshold value on a service by using the CLI

At the command prompt, type:

```
set service <name> -monThreshold <Value>
```

Example:

```
set service Service-HTTP-1 -monThreshold 100
```

To set the monitor threshold value on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Monitor Threshold**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Set a timeout value for idle client connections

September 14, 2021

You can configure the service with a time-out value to terminate any idle client connections when the configured time elapses. If the client is idle during the configured time, the Citrix ADC appliance closes the client connection.

To set a timeout value for idle client connections by using the CLI

At the command prompt, type:

```
set service <name> -cltTimeout <Value>
```

Example:

```
set service Service-HTTP-1 -cltTimeout 100
```

To set a timeout value for idle client connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Client Idle Time-out**.

Set a timeout value for idle server connections

September 14, 2021

You can configure a service with a timeout value to terminate any idle server connections when the configured time (in seconds) elapses. If the server is idle for the configured amount of time, the Citrix ADC appliance closes the server connection.

To set a timeout value for idle server connections by using the CLI

At the command prompt, type:

```
set service <name> -svrTimeout <Value>
```

Example:

```
set service Service-HTTP-1 -svrTimeout 100
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set a timeout value for idle server connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Server Idle Time-out**.

Set a limit on the bandwidth usage by clients

September 14, 2021

Sometimes, servers might have limited bandwidth to handle client requests and might become overloaded. To prevent overloading a server, you can specify a maximum limit on the bandwidth, in Kbps, processed by the server. The Citrix ADC appliance forwards requests to a load balanced server only until this limit is reached.

To set a maximum bandwidth limit on a service by using the CLI

At the command prompt, type:

```
set service <name> -maxBandwidth <Value>
```

Example:

```
set service Service-HTTP-1 -maxBandwidth 100
```

To set a maximum bandwidth limit on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Bandwidth**.

Redirect client requests to a cache

September 14, 2021

You can configure a service to redirect client requests to a cache, and forward the non-cacheable requests to a service chosen by the configured load balancing method.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set cache redirection on a service by using the CLI

At the command prompt, type:

```
set service <name> -cacheable <Value>
```

Example:

```
set service Service-HTTP-1 -cacheable YES
```

To set cache redirection on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service, and set the Cache Type.

Retain the VLAN identifier for VLAN transparency

September 14, 2021

You can configure a load balancing virtual server to retain the client's VLAN identifier in packets that are to be forwarded to servers. The virtual server must be a wildcard virtual server of type ANY, and must be functioning in MAC mode.

To configure a load balancing virtual server to retain the client VLAN ID by using the CLI

At the command prompt, type the following command to configure a load balancing virtual server to retain the client VLAN ID and verify the configuration:

```
set lb vserver <name> -m MAC -macmodeRetainvlan ENABLED

show lb vserver <name>
```

> **Note**
>
> For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

To configure a load balancing virtual server to retain the client VLAN ID by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. In Advanced Settings, select **Traffic Settings**, and select **Retain VLAN ID**.

Configure automatic state transition based on percentage health of bound services

September 14, 2021

You can configure a load balancing virtual server to automatically transition from the UP state to the DOWN state if the percentage of active services falls below a configured threshold. For example, if you bind 10 services to a load balancing virtual server and configure a threshold of 50% for that virtual server, it transitions from UP to DOWN if six or more services are DOWN. When the percentage health rises above the threshold value, the virtual server returns to the UP state.

You can also enable an SNMP alarm called ENTITY-STATE if you want the Citrix ADC appliance to notify you when the percentage health of bound services causes a virtual server to change state.

To configure percentage based automatic state transition by using the CLI

At the command prompt, type the following commands to configure an automatic state transition for a virtual server and verify the configuration:

```
set lb vserver <name> -healthThreshold <positive_integer>

show lb vserver <name>
```

To configure percentage based automatic state transition by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and set a **Health Threshold**.

To enable the ENTITY-STATE alarm by using the CLI

At the command prompt, type the following commands to enable the ENTITY-STATE SNMP alarm and verify the configuration:

```
enable snmp alarm ENTITY-STATE

show snmp alarm
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable the ENTITY-STATE alarm by using the GUI

1. Navigate to **System > SNMP > Alarms**.
2. Select **ENTITY-STATE** and, in the Action list, select **Enable**.

Built-in monitors

September 14, 2021

The Citrix ADC appliance contains various built-in monitors that you can use to monitor your services. These built-in monitors handle most of the common protocols. They provide options to modify some parameters, such as interval, response time-out to meet your requirements. However, you cannot modify the monitor name and protocol. For more information, see Modifying Monitors. You can also bind a built-in monitor to a service and unbind it from the service.

> **Note**
>
> You can create a custom monitor based on a built-in monitor. To learn how to create custom monitors, see Configuring Monitors in a Load Balancing Setup.

TCP-based application monitoring

September 14, 2021

The Citrix ADC appliance has two built-in monitors that monitor TCP-based applications: `tcp-default` and `ping-default`. When you create a service, the appropriate default monitor is bound to it automatically, so that the service can be used immediately if it is UP. The tcp-default monitor is bound to all TCP services. The ping-default monitor is bound to all non-TCP services.

You can't delete or modify default monitors. When you bind any other monitor to a TCP service, the default monitor is unbound from the service. The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Monitor type	Specific parameters	Process
tcp	Not applicable	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination, and then closes the connection. If the appliance observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is disabled. By default, LRTM is disabled on this monitor.
http	httprequest [“HEAD /”] - HTTP request that is sent to the service. respcode [200] - A set of HTTP response codes are expected from the service.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.
tcp-ecv	send [’”’] - is the data that is sent to the service. The maximum permissible length of the string is 512 bytes. recv [’”’] - expected response from the service. The maximum permissible length of the string is 128 bytes. The last character is NULL termination.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter. Different servers send different sizes of segments. However, the pattern must be within 16 TCP segments.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Monitor type	Specific parameters	Process
http-ecv	send [""] - HTTP data that is sent to the service; recv [""] - the expected HTTP response data from the service	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data might be anywhere in the first 24 K bytes of the HTTP body of the response.
ping	Not Applicable	The Citrix ADC appliance sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response.

To configure built-in monitors for TCP-based applications, see Configuring Monitors in a Load Balancing Setup.

To configure TCP-based monitors by using CLI

Type the following command:

```
add lb monitor <monitorName> <type> -respCode <int[-int]> -httpRequest
    <string> -resptimeout <integer> [<units>] -retries <integer> -
    downTime <integer> [<units>] -action <action>
```

Example for TCP monitor type:

```
add lb monitor Exch2010-RPC-AddressBook TCP -LRTM ENABLED -interval 10
    -resptimeout 5 -destPort 59601
```

Example for HTTP monitor type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add lb monitor Mon_S4B_FE_2 HTTP -respCode 200 -httpRequest "GET /
    Autodiscover/XFrame/XFrame.html" -LRTM ENABLED -retries 10 -secure
    YES
```

Example for HTTP-ECV monitor type:

```
add lb monitor STM_EXC2016_SSLBridge_MON HTTP-ECV -send "GET /owa/
    healthcheck.htm" -recv "200 OK" -LRTM ENABLED -destPort 443 -secure
    YES
```

Example for PING monitor type:

```
add lb monitor lbmon-localhost-ping PING -LRTM DISABLED -destIP
    127.0.0.1
```

SSL service monitoring

October 10, 2023

The Citrix ADC appliance has built-in secure monitors, TCPS, and HTTPS. You can use the secure monitors to monitor HTTP and non-HTTP traffic. To configure a secure HTTP monitor, select the monitor type as HTTP, and then set the secure flag. To configure a secure TCP monitor, select the monitor type as TCP, and then set the secure flag. The secure monitors work as follows:

- **Secure TCP monitoring.** The Citrix ADC appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. After the handshake is over, the appliance closes the connection.
- **Secure HTTP monitoring.** The Citrix ADC appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. When the SSL connection is established, the appliance sends HTTP requests over the encrypted channel and checks the response codes.

The following table describes the available built-in monitors for monitoring SSL services.

Monitor type	Probe	Success criteria (Direct condition)
TCP	TCP connection; SSL handshake	Successful TCP connection established and successful SSL handshake.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Monitor type	Probe	Success criteria (Direct condition)
HTTP	TCP connection; SSL handshake; Encrypted HTTP request	Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP response code in server HTTP response is encrypted.
TCP-ECV	TCP connection. SSL handshake (Data sent to a server is encrypted.)	Successful TCP connection is established, successful SSL handshake is performed, and expected TCP data is received from the server.
HTTP-ECV	TCP connection; SSL handshake (Encrypted HTTP request)	Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP data is received from the server.

Sample configuration for HTTP-ECV health check monitor

HTTP services have predefined monitors capable of Extended Content Verification (ECV).
These monitors are used when a validation is required beyond a successful TCP connection. These monitors validate the service as UP, when all the following criteria are met:

- A successful TCP connection.
- A particular type of request must be generated.
- A specific message is expected in reply from the **Receive String**.

For these monitors, a request string is configured along with a reply string. If the reply string received by the Citrix ADC monitor matches the configured string, then the service is marked UP.

Bind a monitor to a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**, create a service, and specify the protocol as **SSL**. Click **OK**.
2. Click in the **Service to Load Balancing Monitor Binding** pane, and click **Add Binding**.
3. Choose the monitor type as **HTTP-ECV** and click **Edit**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. In the **Configure Monitor** pane under **Basic Parameters** tab, enter values for the following parameters:
   - **Send String** –The string that the monitor must send to the service.
   - **Receive String** –The string that the monitor must receive to mark the service as UP.
5. Click **OK** to complete the monitor configuration.
6. Click **Select**.
7. Click **Bind** to bind the **HTTP-ECV** monitor to the service.
8. Click **Close**.

Create and bind a monitor to a service by using the CLI

At the command prompt, type:

```
add lb monitor <monitor-name> http-ecv
bind service <servicename> -monitorName <monitor-name>
```

Example:

```
add lb monitor monitor-1 http-ecv
bind service services1 -monitorName monitor-1
```

HTTP/2 service monitoring

September 14, 2021

Citrix ADC appliance supports HTTP/2 monitors for monitoring the health status of HTTP/2 services.

HTTP/2 monitor can be configured in two different ways. Depending on the traffic type, you can configure an HTTP/2 monitor.

- **HTTP/2 Direct.** You can configure HTTP/2 Direct for monitoring non-secure HTTP/2 services.
- **HTTP/2 SSL.** You can configure HTTP/2 SSL for monitoring secure traffic over SSL. Enable the secure flag parameter in the HTTP/2 to monitor the SSL traffic.

The http2direct and http2ssl are the two different built-in monitors that are supported for the HTTP/2 protocol.

The following table lists the configuration types, and monitoring processes associated with each type.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuration type	Probe	Success criteria
HTTP/2 Direct	TCP Connection; HTTP2 Connection preface & Settings Negotiation; HTTP2 Request	HTTP/2 response status code must match the configured response code.
HTTP/2 SSL	TCP Connection; SSL Handshake; HTTP2 Connection preface & Settings Negotiation; HTTP2 Request	The server must always select ALPN with the HTTP/2 protocol and the HTTP/2 response status code must match the configured response code.

Bind the HTTP/2 monitor to a service by using the CLI

At the command prompt, type:

- `bind service <servicename> -monitorName <name>`
- `bind service <servicename> -monitorName <name>`

Example:

- `bind service s1 -monitorName http2direct`
- `bind service s2 -monitorName http2ssl`

Proxy protocol service monitoring

September 14, 2021

Citrix ADC appliance with a proxy protocol supports monitor check. The monitor check ensures that the back end server also supports the proxy protocol. The Citrix ADC appliance has four built-in monitor types for HTTP or TCP related services: HTTP, HTTPS, HTTP-ECV, and TCP-ECV.

The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuration type	Probe	Success criteria
HTTP	`httprequest` [“HEAD /”] - HTTP request that is sent to the service. `respcode` [200] - A set of HTTP response codes are expected from the service.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.
HTTPS	`httprequest` [“HEAD /”] - HTTPS request that is sent to the service. `respcode` [200] - A set of HTTPS response codes are expected from the service.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTPS requests, and then compares the response code with the configured set of response codes.
HTTP-ECV	send [’”’] - HTTP data that is sent to the service. Received [’”’] - the expected HTTP response data from the service	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data might be anywhere in the first 24 K bytes of the HTTP body of the response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuration type	Probe	Success criteria
TCP-ECV	send [’”’] - is the data that is sent to the service. The maximum permissible length of the string is 512 K bytes. received [’”’] - the expected response from the service. The maximum permissible length of the string is 128 K bytes.	The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter. Different servers send different sizes of segments. However, the pattern must be within 16 TCP segments.

You can configure the proxy protocol monitor using `netprofile`.

Configure proxy protocol monitor by using the CLI

At the command prompt, type:

1. Add net profile with proxy protocol enabled

   ```
   add netprofile <name> -proxyProtocol ( ENABLED | DISABLED )
   ```

Example:

```
1 add netprofile profile1 – proxyProtocol ENABLED
```

1. Bind the net profile to a service.

   ```
   set service <name> -netprofile <netprofile-name>
   ```

Example:

```
1 set service S1 – netprofile profile1
```

> **Note**
>
> You can run the preceding command if you want net profile to bound to a service.

1. Bind the net profile to a monitor.

   ```
   set lb monitor <monitor-name> <type> -netprofile <netprofile-name
   >
   ```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
set lb monitor http1 HTTPS  – netprofile profile1
```

> **Note**
>
> - You can run the preceding command if you want the net profile to bound to a monitor.
> - You can select a monitor type of your choice. It can be HTTP, HTTPS, TCP-ECV, or HTTP-ECV.
>
> **Important**
>
> - In a general case, the net profile (proxy protocol enabled) bound to a service is considered.
> - If the net profile is bound to both monitor and service, the net profile bound to monitor is considered. The net profile bound to service is ignored.

FTP service monitoring

September 14, 2021

To monitor FTP services, the Citrix ADC appliance opens two connections to the FTP server. It first connects to the control port, which is used to transfer commands between a client and an FTP server. After it receives the expected response, it connects to the data port, which is used to transfer files between a client and an FTP server. Only when the FTP server responds as expected, on both the connections, it is marked UP.

Note: Monitor probes originate from the NSIP address.

The Citrix ADC appliance has two built-in monitors for FTP services: the FTP monitor and the FTP-EXTENDED monitor. The FTP-EXTENDED monitor is a scriptable monitor. It uses the nsftp.pl script. The FTP-EXTENDED monitor script is enhanced to send secure probes to FTP services. You can create a monitor of type FTP-EXTENDED. The nsftp.pl script is automatically taken from the default directory.

To send secure FTP probes to FTP services by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <type> -username <string> -password <
    string> -filename <filename>
```

Example

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add monitor mon1 FTP-EXTENDED -username root -password freebsd -
    filename fsdf
```

To send secure FTP probes to FTP services by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**.
2. Specify the monitor type as **FTP-EXTENDED**, and set the parameters.
3. In **Special Parameters**, specify a **File Name**, **User Name**, and **Password**.

To configure built-in monitors to check the state of FTP services, see Configuring Monitors in a Load Balancing Setup.

Secure monitoring of servers by using SFTP

September 14, 2021

A user script 'nssftp.pl'is added to support SSH File Transfer Protocol (SFTP) monitoring. It is available in the current list of in-built Citrix ADC user monitors and is located in the /netscaler/monitors directory. The SFTP monitor uses the specified user name and password to check if the file is present on the server.

To configure secure monitoring using SFTP by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
    string> -secure ( YES | NO )
```

Example:

```
add monitor SFTP_MON USER –scriptname nssftp.pl –scriptargs “file=
    example.txt;user=sam;password=sam_passwd ”
```

To configure secure monitoring using SFTP by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors** and in **Type** specify **USER**.
2. In **Special Parameters**, in **Script Name**, select nssftp.pl.
3. Specify the **Script Arguments**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Set SSL parameters on a secure monitor

September 14, 2021

> **Important**
>
> This feature is supported only on the new Default profiles. For more information about these profiles, see Enhanced SSL Profiles Infrastructure Overview.

A monitor inherits either the global settings or the settings of the service to which it is bound. If a monitor is bound to a non-SSL or non-SSL_TCP service, such as SSL_BRIDGE, you cannot configure it with SSL settings such as the protocol version or the ciphers to be used. Therefore, if your deployment requires SSL-based monitoring of the back-end servers, the monitoring is ineffective.

You can have more control over SSL-based monitoring of back-end servers, by binding an SSL profile to a monitor. An SSL profile contains SSL parameters, cipher bindings, and ECC bindings. For example, you can set server authentication, ciphers, and protocol version in an SSL profile and bind the profile to a monitor. To perform server authentication, you must also bind a CA certificate to a monitor. To perform client authentication, you must bind a client certificate to the monitor. New parameters for the "bind lb monitor"command enable you to do so.

> **Note**
>
> The SSL settings take effect only if you add a secure monitor. Also, the SSL profile type must be **BackEnd**.

Monitor Types that Support SSL Profiles

SSL profiles can be bound to the following monitor types:

- HTTP
- HTTP-ECV
- TCP
- TCP-ECV
- HTTP-INLINE

To specify an SSL profile while adding a monitor by using the command line

At the command prompt, type:

```
add lb monitor <monitorName> <type> -secure  YES   -sslprofile <string>

set lb monitor <monitorName> <type> -secure YES -sslprofile <string>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
add ssl profile prof1 -sslProfileType  BackEnd

add lb monitor mon1 HTTP -secure  YES -sslprofile prof1
```

To bind a certificate-key pair to a monitor by using the command line

At the command prompt, type:

```
bind monitor  <monitor name> -certkeyName <string>  [(-CA  [-crlCheck (
      Mandatory | Optional ) | -ocspCheck ( Mandatory | Optional )]
```

SIP service monitoring

August 23, 2024

A Citrix ADC has two built-in monitors that you can use to monitor SIP services: the **SIP-UDP** and **SIP-TCP** monitors. A SIP monitor periodically checks the SIP service to which the SIP monitor is bound, by sending SIP request methods to the SIP service. If the SIP service replies with a response code, the monitor marks the service as UP. If the SIP service does not respond, or responds incorrectly, it is marked as DOWN.

Parameter	Specifies
sipURI	SIP addressing schema of the SIP server.
`sipmethod`	Type of SIP request used to probe the SIP service. Specify one of the following methods: INVITE, OPTION (the default), REGISTER
`respcode`	SIP response code with which the SIP service responds the probe request. Default: 200.

To configure SIP service monitoring using the CLI

At the command prompt, type:

```
add lb monitor <Monitor Name> <type> -respCode -sipMethod -sipURI
```

Example:

```
add lb monitor sip_mon1 -TCP -respCode 200 -sipMethod REGISTER -
sipURI sip:mon@test.com
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure SIP service monitoring using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Click **Add** and create a monitor of type that meets your requirement.
3. Update the parameters and click **Create**.

For more information on how to configure the built-in SIP monitor, see Configuring Monitors in a Load Balancing Setup.

RADIUS service monitoring

September 14, 2021

The Citrix ADC appliance RADIUS monitor periodically checks the state of the RADIUS service to which it is bound by sending an authentication request to the service. The RADIUS server authenticates the RADIUS monitor and sends a response. By default, the monitor expects to receive a response code of 2, the default Access-Accept response, from the RADIUS server. As long as the monitor receives the appropriate response, it marks the service UP.

Note: RADIUS monitor supports only PAP type authentication.

- If the client authenticated successfully, the RADIUS server sends an Access-Accept response. The default access-accept response code is 2, and this is the code that the appliance uses.
- If the client fails to authenticate successfully (such as when there is a mismatch in the user name, password, or secret key), the RADIUS server sends an Access-Reject response. The default access-reject response code is 3, and this is the code that the appliance uses.

Parameter	Specifies
`userName`	User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.
password	Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.
radKey	Shared secret key value that the RADIUS server uses during client authentication.
radNASid	NAS-ID that is encapsulated in the payload when an access request is made.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Parameter	Specifies
radNASip	The IP address that is encapsulated in the payload when an access-request is made. When radNASip is not configured, the Citrix ADC appliance sends the mapped IP address (MIP) to the RADIUS server as the NAS IP address.

To monitor a RADIUS service, you must configure the RADIUS server to which it is bound as follows:

1. Add the user name and password of the client that the monitor uses for authentication to the RADIUS authentication database.
2. Add the IP address and secret key of the client to the appropriate RADIUS database.
3. Add the IP addresses that the appliance uses to send RADIUS packets to the RADIUS database. If the Citrix ADC appliance has more than one mapped IP address, or if a subnet IP address (SNIP) is used, you must add the same secret key for all the IP addresses.

   Caution: If the IP address used by the appliance is not added to the RADIUS database, the RADIUS server discards all packets.

To configure built-in monitors to check the state of the RADIUS server, see Configuring Monitors in a Load Balancing Setup.

Monitor accounting information delivery from a RADIUS server

September 14, 2021

You can configure a monitor called a *RADIUS accounting* monitor to determine whether the RADIUS server used for Authentication, Authorization, and Accounting (Citrix ADC AAA) is delivering accounting information as expected. The monitor is of type RADIUS_ACCOUNTING. The probe is generated by a Perl script called nsbmradius.pl, which is located in the /nsconfig/monitors/ directory. The script sends successive accounting request probes to the RADIUS server. The probe is considered successful only if the RADIUS accounting server responds with a packet whose Code field is set to 5, which, according to RFC 2866, indicates an Accounting-Response packet.

When configuring a RADIUS accounting monitor, you must specify a secret key. You can specify optional parameters, each of which represents a RADIUS attribute, such as Acct-Status-Type and Framed-IP-Address. For information about these attributes, see RFC 2865, "Remote Authentication Dial In User Service (RADIUS),"and RFC 2866, "RADIUS Accounting."

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure a RADIUS accounting monitor by using the command line interface

At the command prompt, type the following commands to configure a RADIUS accounting monitor and verify the configuration:

```
add lb monitor <monitorName> RADIUS_ACCOUNTING [-userName <string>] {
 -password  }
  {
 -radKey  }
  [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-
     radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-
     radAccountSession <string>]

show lb monitor <monitorName>
```

Example

```
add lb monitor radAccntMon RADIUS_ACCOUNTING -radKey "8d#>9jr4rV)L7%a2-
   zW13sM"
```

DNS and DNS-TCP service monitoring

September 14, 2021

The Citrix ADC appliance has two built-in monitors that can be used to monitor DNS services: DNS and DNS-TCP. When bound to a service, either monitor periodically checks the state of that DNS service by sending a DNS query to it. The query resolves to an IPv4 or IPv6 address. That IP address is then checked against the list of test IP addresses that you configure. The list can contain up to five IP addresses. If the resolved IP address matches at least one IP address on the list, the DNS service is marked as up. If the resolved IP does not match any IP addresses on the list, the DNS service is marked as down.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Parameter	Description			
query	The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “	query	The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “\007”If the DNS query succeeds, the service is marked as UP. Otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN. Otherwise, it is marked as UP. If no response is received, the service is marked as DOWN.	07”If the DNS query succeeds, the service is marked as UP. Otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN. Otherwise, it is marked as UP. If no response is received, the service is marked as DOWN.
queryType	The type of DNS query that is sent. Possible values: Address, Zone.			
IPAddress	List of IP addresses that are checked against the response to the DNS monitoring probe.			

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Parameter	Description
IPv6	Select this check box if the IP address uses the IPv6 format.

To configure the built-in DNS or DNS-TCP monitors, see Configuring Monitors in a Load Balancing Setup.

LDAP service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor LDAP services: the LDAP monitor. It periodically checks the LDAP service to which it is bound by authenticating and sending a search query to it. If the search is successful, the service is marked UP. If the LDAP server does not locate the entry, a failure message is sent to the LDAP monitor, and the service is marked DOWN.

Configure the LDAP monitor to define the search that it must perform when sending a query. You can use the Base DN parameter to specify a location in the directory hierarchy where the LDAP server must start the test query. You can use the Attribute parameter to specify an attribute of the target entity.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
baseDN	Base name for the LDAP monitor from where the LDAP search must start. If the LDAP server is running locally, the default value of base is dc=`netscaler`, dc=com.
bindDN	BDN name for the LDAP monitor.
filter	Filter for the LDAP monitor. Use the filter parameter in a query to limit the number of results. If you do not specify this parameter in the query, the filter applies for the entire object class, which might be a costly operation, such as a high CPU usage.
password	Password used in monitoring LDAP servers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Parameter	Specifies
attribute	Attribute for the LDAP monitor.

To configure the built-in LDAP monitor, see Configuring Monitors in a Load Balancing Setup.

MySQL service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor MySQL services: the MySQL monitor. It periodically checks the MySQL service to which it is bound by sending a search query to it. If the search is successful, the service is marked UP. If the MySQL server does not respond or the search fails, a failure message is sent to the MySQL monitor, and the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
database	Database that is used for the MySQL monitor.
sqlQuery	SQL query that is used for the MySQL monitor.

To configure a built-in MySQL monitor, see Configuring Monitors in a Load Balancing Setup.

To configure MySQL monitors by using CLI

Type the following command:

```
1 add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
     string>
```

Example:

```
1 add lb monitor mysql1 USER -scriptName nsmysql.pl -scriptArgs "database
     =cloud;user=cloud;password=password;query=show tables from cloud"
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

SNMP service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor SMNP services: the SNMP monitor. It periodically checks the SNMP agent on the service to which it is bound by sending a query for the enterprise identification ID (OID) that you configure for monitoring. If the query is successful, the service is marked UP. If the SNMP service finds the OID that you specified, the query succeeds and the SNMP monitor marks the service UP. If it does not find the OID, the query fails and the SNMP monitor marks service DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
SNMPOID	OID that is used for the SNMP monitor.
snmpCommunity	Community that is used for the SNMP monitor.
snmpThreshold	Threshold that is used for the SNMP monitor.
snmpVersion	SNMP version that is used for load monitoring. Possible Values: V1, V2.

To configure the built-in SNMP monitor, see Configuring Monitors in a Load Balancing Setup.

NNTP service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor NNTP services: the NNTP monitor. It periodically checks the NNTP service to which it is bound by connecting to the service and checking for the existence of the newsgroup that you specify. If the newsgroup exists, the search is successful and the service is marked UP. If the NNTP service does not respond or the search fails, the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

The NNTP monitor can optionally be configured to post a test message to the newsgroup as well.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Parameter	Specifies
userName	User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.
password	Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.
group	Group name to be queried for NNTP monitor.

To configure the built-in NNTP monitor, see Configuring Monitors in a Load Balancing Setup.

POP3 service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor POP3 services: the POP3 monitor. It periodically checks the POP3 service to which it is bound by opening a connection with a POP3 server. If the POP3 server responds with the correct response codes within the configured time period, it marks the service UP. If the POP3 service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
userName	User name POP3 server. This user name is used in the probe.
password	Password used in monitoring POP3 servers.
scriptName	The path and name of the script to execute.
dispatcherIP	The IP address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.

To configure the built-in POP3 monitor, see Configuring Monitors in a Load Balancing Setup.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure POP3 monitors by using CLI

Type the following command:

```
add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
    string>
```

Example:

```
add lb monitor pop31 USER -scriptName nspop3.pl -scriptArgs "user=
    test@lbmon1.net;password=Freebsd123"
```

SMTP service monitoring

September 14, 2021

The Citrix ADC appliance has a built-in monitor that can be used to monitor SMTP services: the SMTP monitor. The monitor checks the SMTP service to which it is bound by opening a connection with it and conducting a series of handshakes to ensure that the server is operating correctly. If the SMTP service completes the handshakes properly, the monitor marks the service UP. Else, if the SMTP service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
scriptName	The path and name of the script to run.
dispatcherIP	The IP Address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.

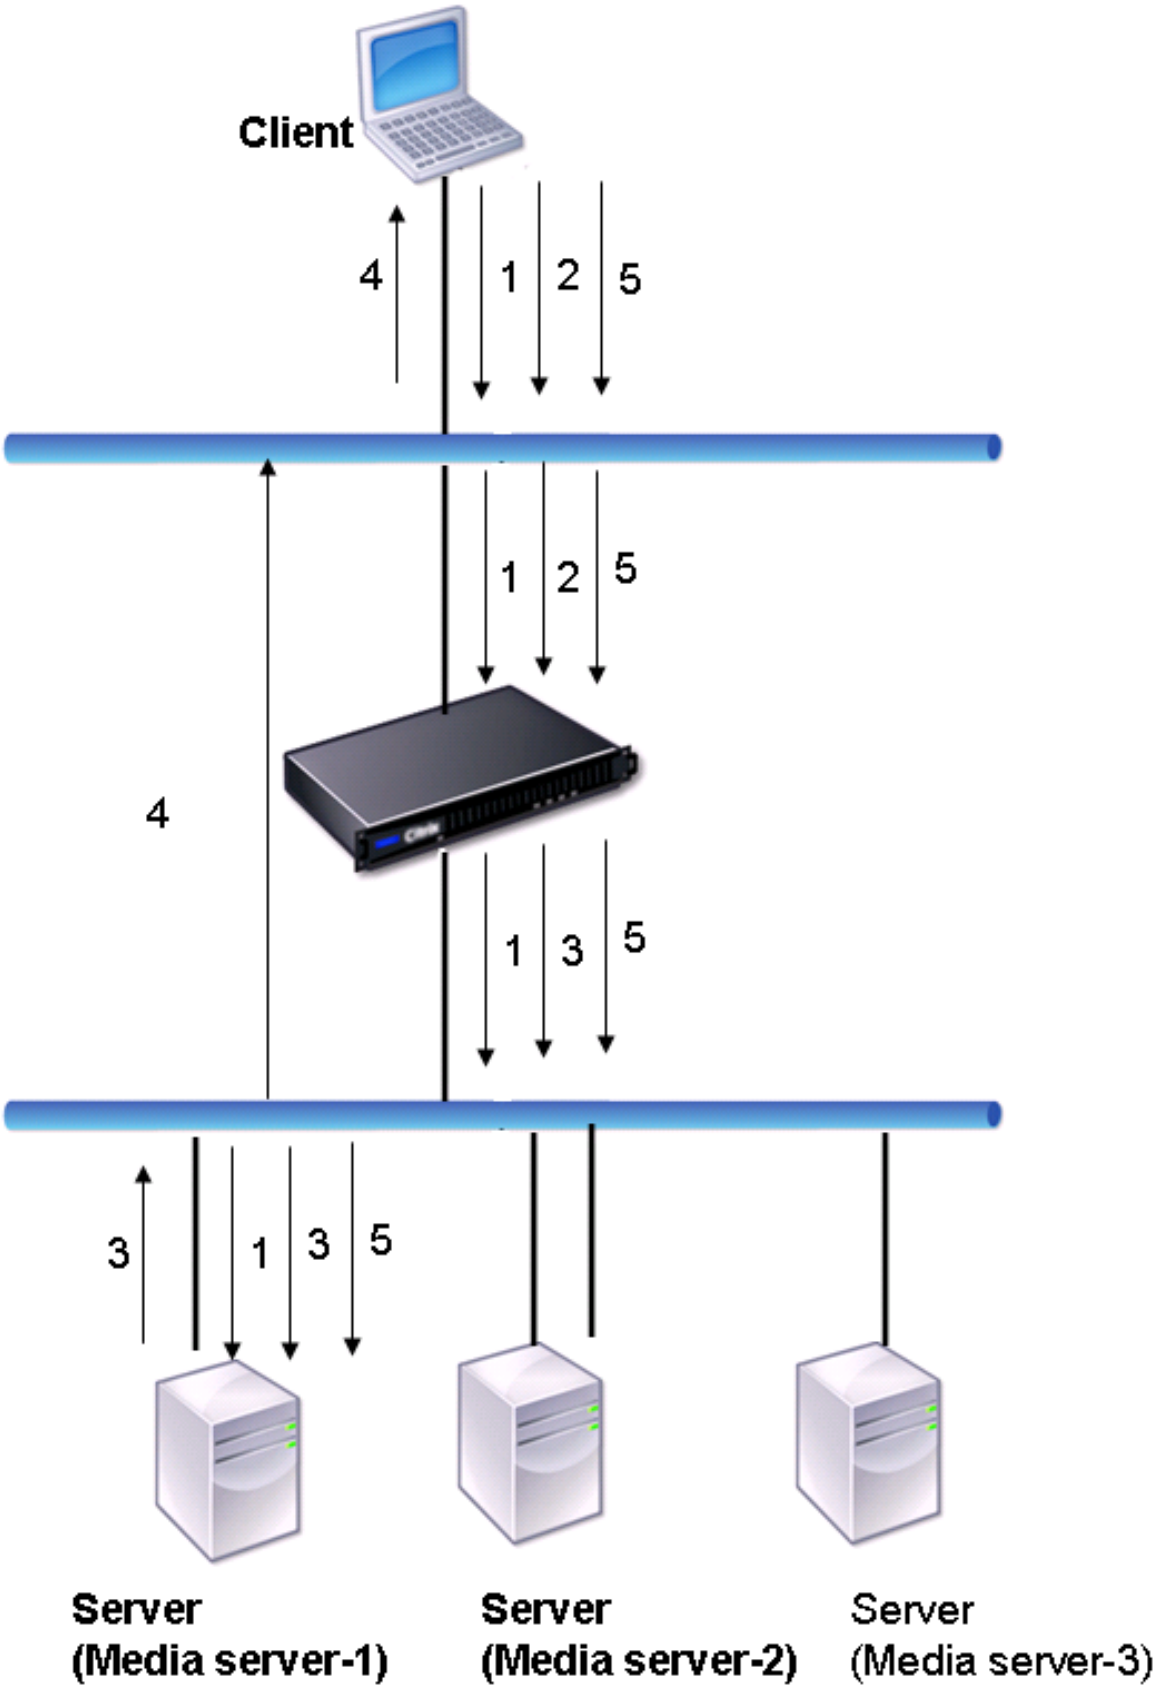
To configure the built-in SMTP monitor, see Configuring Monitors in a Load Balancing Setup.

RTSP service monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor RTSP services: the RTSP monitor. It periodically checks the RTSP service to which it is bound by opening a connection

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



with the load balanced RTSP server. The type of connection that it opens, and the response that it expects, differs depending upon the network configuration. If the RTSP service responds as expected within the configured time period, it marks the service UP. If the service does not respond, or responds incorrectly, it marks the service DOWN.

The Citrix ADC appliance can be configured to load balance RTSP servers using two topologies: NAT-off and NAT-on. RTSP servers send their responses directly to the client, bypassing the appliance. The appliance must be configured to monitor RTSP services differently depending upon which topology your network uses. The appliance can be deployed either in inline or non-inline mode in both NAT-off and NAT-on mode.

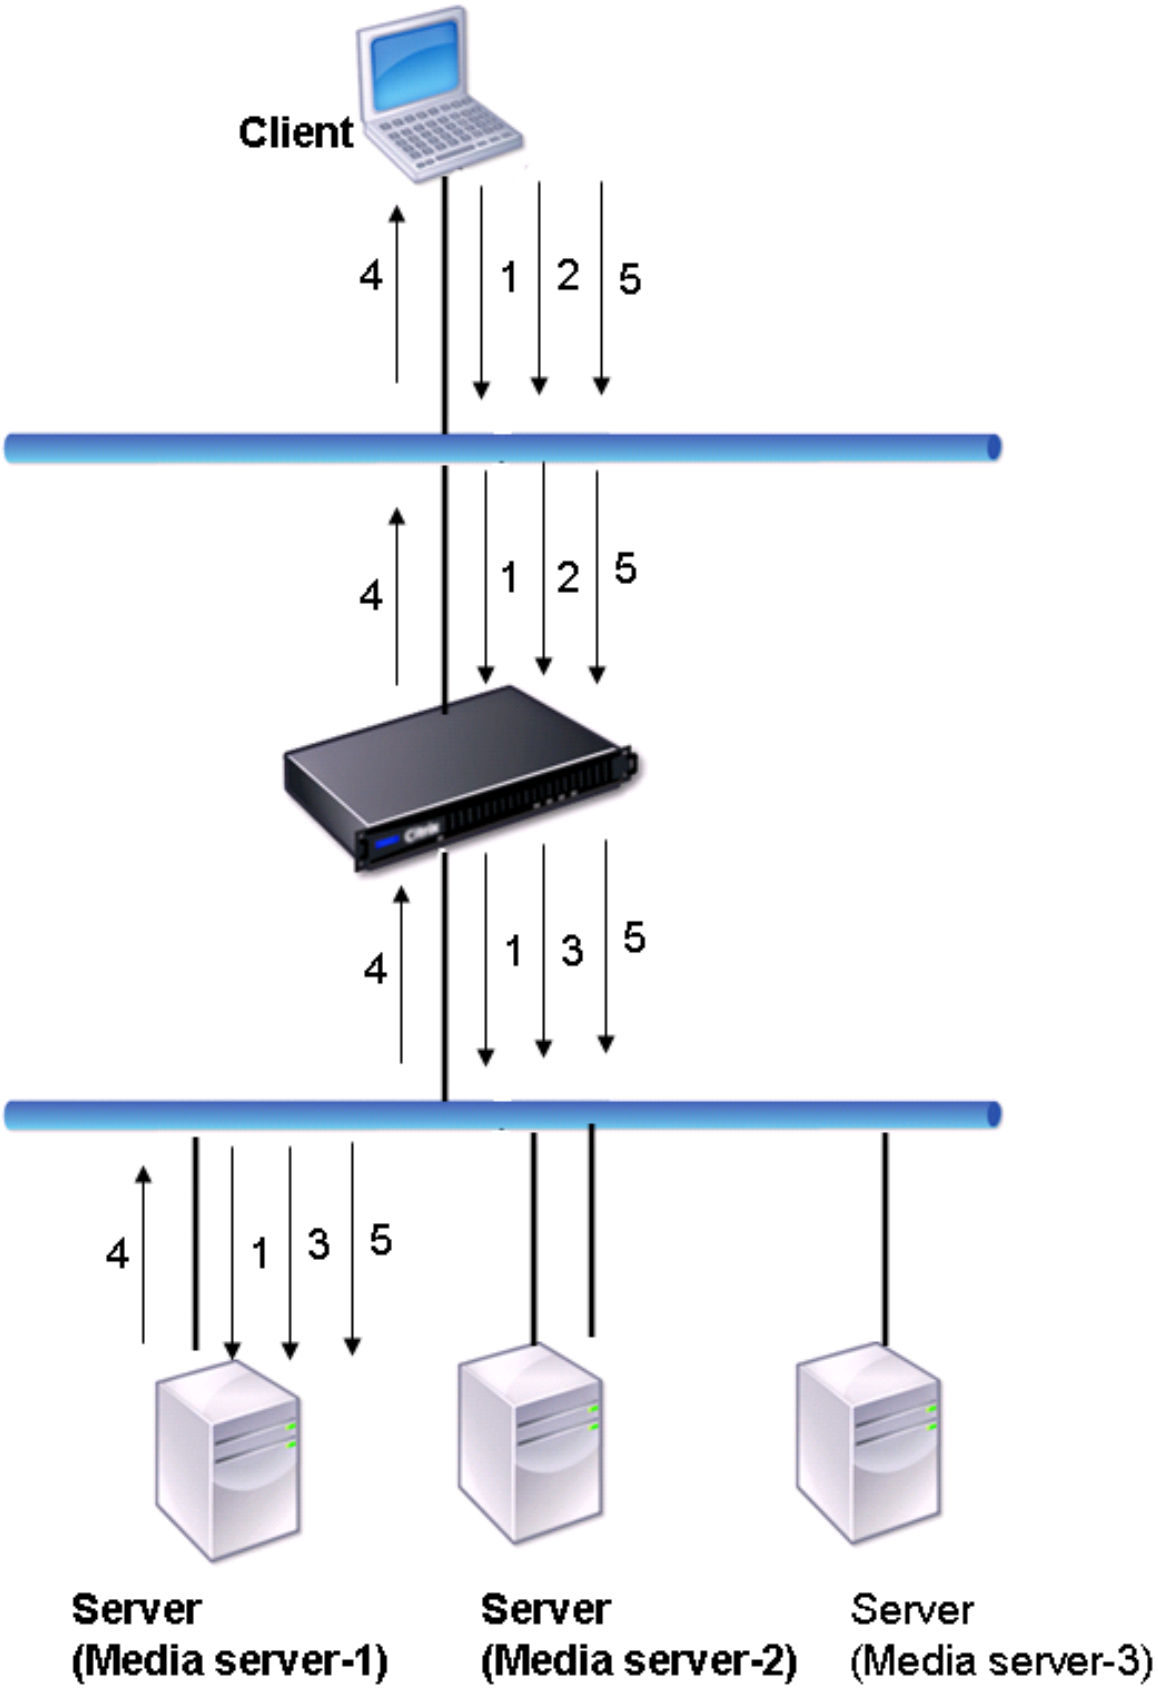
In NAT-off mode, the appliance operates as a router: it receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. If your load balanced RTSP servers are assigned publicly accessible FQDNs in DNS, the load balanced servers send their responses directly to the client, bypassing the appliance. The following figure demonstrates this configuration.

Figure 1. RTSP in NAT-off Mode

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The flow of requests and responses in this scenario is as follows:



1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
    - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
    - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request might be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

    Note: The appliance does not perform NAT to identify the RTSP connection, because the RTSP connections bypass it.
4. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the media server. Media Server-1 performs the requested actions, such as play, forward, or rewind.

In NAT-on mode, the appliance receives RTSP requests from the client and routes those requests to the appropriate media server using the configured load balancing method. The media server then sends its responses to the client through the appliance, as illustrated in the following diagram.

Figure 2. RTSP in NAT-on Mode

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using the RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
   - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
   - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request might be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.
4. The appliance performs NAT to identify the client for RTSP data connections, and the RTSP connections pass through the appliance and are routed to the correct client.
5. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the appliance. The appliance uses RTSPSID persistence to identify the appropriate service, and routes the request to Media Server-1. Media Server-1 performs the requested action, such as play, forward, or rewind.

The RTSP monitor uses the RTSP protocol to evaluate the state of the RTSP services. The RTSP monitor connects to the RTSP server and conducts a sequence of handshakes to ensure that the server is operating correctly.

Parameter	Specifies
rtspRequest	The RTSP request string that is sent to the RTSP server (for example, OPTIONS *). The default value is 07. The length of the request must not exceed 163 characters.
respCode	Set of response codes that are expected from the service.

For instructions on configuring an RTSP monitor, see Configuring Monitors in a Load Balancing Setup.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

XML Broker Service monitoring

July 24, 2023

The Citrix ADC appliance has a built-in monitor type, `CITRIX-XML-SERVICE`, with which you can create monitors to monitor the XML Broker Services. The XML Broker Services are used by Citrix Virtual Apps. The monitor opens a connection to the service and periodically probes the XML services to which it is bound. If the server responds as expected within the configured time period, the monitor marks the service UP. If the service does not respond, or responds incorrectly, the monitor marks the service DOWN.

To configure a `CITRIX-XML-SERVICE` monitor, you need to specify the application name in addition to setting the standard parameters. The application name is the name of the application that has to be run to monitor the state of the XML Broker Service. The default application is Notepad.

To configure monitors for XML Broker Services, see Configuring Monitors in a Load Balancing Setup.

> **Note:**
>
> The `CITRIX-XML-SERVICE` monitor is not supported for Citrix Virtual Apps and Desktops versions 7 and later. It is recommended to use `CITRIX-XD-DDC` monitor. For more information on `CITRIX-XD-DDC` monitor, see Citrix Virtual Desktops Delivery Controller service monitoring. However, you can use the `CITRIX-XML-SERVICE` monitor in versions earlier to XA/XD 7.

ARP request monitoring

September 14, 2021

The Citrix ADC appliance has one built-in monitor that can be used to monitor ARP requests: the ARP monitor. This monitor periodically sends an ARP request to the service to which it is bound, and listens for the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

ARP locates a hardware address for a load balanced server when only the network layer address is known. ARP is compatible with IPv4 to translate IP addresses to Ethernet MAC addresses. ARP monitoring is not relevant to IPv6 networks, and is therefore not supported on those networks.

There are no special parameters for the ARP monitor.

For instructions on configuring an ARP monitor, see Configuring Monitors in a Load Balancing Setup.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

XenDesktop Delivery Controller service monitoring

September 14, 2021

In desktop virtualization, the Citrix ADC appliance can be used to load balance the Web Interface (WI) servers and the XenDesktop Delivery Controller servers deployed by the Citrix XenDesktop environment. The Citrix ADC appliance provides a built-in monitor, CITRIX-XD-DDC monitor, which monitors the XenDesktop Delivery Controller servers. In addition to the health check, you can also verify whether the probe is sent by a valid user of the XenDesktop Delivery Controller server.

The monitor sends a probe to the XenDesktop Delivery Controller server in the form of an XML message. If the server responds to the probe with the identity of the server farm, the probe is considered to be successful and the server's status is marked as UP. If the HTTP response does not have a success code or the identity of the server farm is not present in the response, the probe is considered to be a failure and the server's status is marked as DOWN.

The Validate Credentials option determines the probe to be sent by the monitor to the XenDesktop Delivery Controller server, that is, whether to request only the server name or to also validate the login credentials.

Note: Regardless of whether the user credentials (user name, password, and domain) are specified on the
CITRIX-XD-DDC monitor, the XenDesktop Delivery Controller server validates the user credentials only if the option to validate credentials is enabled on the monitor.

If you use the wizard for configuring the load balancing of the XenDesktop servers, the CITRIX-XD-DDC monitor is automatically created and bound to the XenDesktop Delivery Controller services.

To add an XD-DDC monitor with the validate credentials option by using the command line interface

At the command prompt, type the following commands to add an XD-DDC monitor and verify the configuration:

```
add lb monitor <monitorName> <monitorType> -userName <userName> -
    password <password> -domain <domain_name> -validateCred YES

show lb monitor <monitorName>
```

Example:

```
 > add lb monitor xdddcmon Citrix-xd-ddc -userName Administrator -
     password E12Dc35450a1 -domain dhop -validateCred YES
 Done
> show lb monitor xdddcmon
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Special parameters:
User Name..........:"Administrator"
Password..........:*****
DDC Domain.........: "dhop"
Done
```

To specify the validate credentials option on an XD-DDC monitor by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <monitorType> -userName -password -domain
    <domain_name> -validateCred YES
```

Example:

```
 set lb monitor XD_DDC_21.21.21.22_443_mn CITRIX-xd-ddc -userName
     Administrator -password D123S1R2A123 -domain dhop -validateCred YES
Done
```

To configure an XD-DDC monitor with the validate credentials option by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Monitors**, and create a monitor of type `Citrix-XD-DDC`.

Citrix StoreFront stores monitoring

December 8, 2022

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

You can configure a user monitor for a Citrix StoreFront store. The monitor determines the state of the StoreFront store by successively probing the account service, discovery service, and authentication endpoint (if the Citrix StoreFront Store is an authenticated store). If any of those services do not respond to the probe, the monitor probe fails, and the StoreFront store is marked as DOWN. The monitor sends probes to the IP address and port of the bound service. For more information, see Citrix StoreFront Store Services API.

Note: Monitor probes originate from the NSIP address. However, if the subnet of a StoreFront server is different from that of the appliance, then the subnet IP (SNIP) address is used.

Beginning with release 10.1 build 120.13, you can also bind a StoreFront monitor to a service group. A monitor is bound to each member of the service group and probes are sent to the IP address and port of the bound member (service). Also, because each member of a service group is now monitored by using the member's IP address, you can now use the StoreFront monitor to monitor StoreFront cluster nodes that are added as members of the service group.

In earlier releases, the StoreFront monitor tried to authenticate anonymous stores. As a result, a service can be marked as DOWN and you cannot launch Citrix Virtual Apps or Citrix Virtual Desktops by using the URL of the load balancing virtual server.

From build 64.x, the probe order has changed. The monitor now determines the state of the StoreFront store by successively probing the account service, the discovery document, and then the authentication service, and skips authentication for anonymous stores.

The host name parameter for StoreFront monitors is deprecated. The secure parameter is now used to determine whether to use HTTP (the default) or HTTPS to send monitor probes.

To use HTTPS, set the secure option to Yes.

To create a StoreFront monitor by using the command line interface

At the command prompt, type the following commands to configure a StoreFront monitor and verify the configuration:

```
1 add lb monitor <monitorName> STOREFRONT <string> -storeName <string> [-
     storefrontacctservice ( YES | NO )] -secure ( YES | NO )
2
3 show lb monitor <monitorName>
```

Example

```
1 add lb monitor storefront_ssl STOREFRONT -storename myStore -
     storefrontacctservice YES -secure YES
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To create a StoreFront monitor by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Monitors**, and create a monitor of type **STOREFRONT**.

> **Note**
>
> For more information about the StoreFront monitors, see StoreFront documentation.

Custom monitors

September 14, 2021

In addition to built-in monitors, you can use custom monitors to check the state of your services. The Citrix ADC appliance provides several types of custom monitors based on scripts that are included with the Citrix ADC operating system. The scripts can be used to determine the state of services based on the load on the service or network traffic sent to the service. Custom monitors are the inline monitors, user monitors, and load monitors.

With these types of monitors, you can use the supplied functionality, or you can create your own scripts and use those scripts to determine the state of the service to which the monitor is bound.

Configure HTTP-inline monitors

September 14, 2021

Inline monitors analyze and probe the responses from the services to which they are bound only when those services receive client requests. The inline monitor is of type HTTP-INLINE and can only be configured with HTTP and HTTPS services. An inline monitor determines that the service to which it is bound is UP by checking its responses to the requests that are sent to it. When no client requests are sent to the service, the inline monitor probes the service by using the configured URL.

Note: Inline monitors cannot be bound to HTTP or HTTPS Global Server Load Balancing (GSLB) remote or local services because these services represent virtual servers rather than actual load balanced Web servers.

Inline monitors have a time-out value and a retry count when probes fail. You can select any of the following action types for the Citrix ADC appliance to take when a failure occurs:

- **NONE.** No explicit action is taken. You can view the service and monitor, and the monitor indicates the number of current contiguous error responses and cumulative responses checked.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **LOG.** Logs the event in ns/syslog and displays the counters.
- **DOWN.** Marks the service down and does not direct any traffic to the service. This setting breaks any persistent connections to the service. This action also logs the event and displays counters.

After the service is down, the service remains DOWN for the configured downtime. After the downtime elapses, the inline monitor uses the configured URL to probe the service to see if it is available again. If the probe succeeds, the state of the service is changed to UP. Traffic is directed to the service, and monitoring resumes as before.

To configure inline monitors, see Configuring Monitors in a Load Balancing Setup.

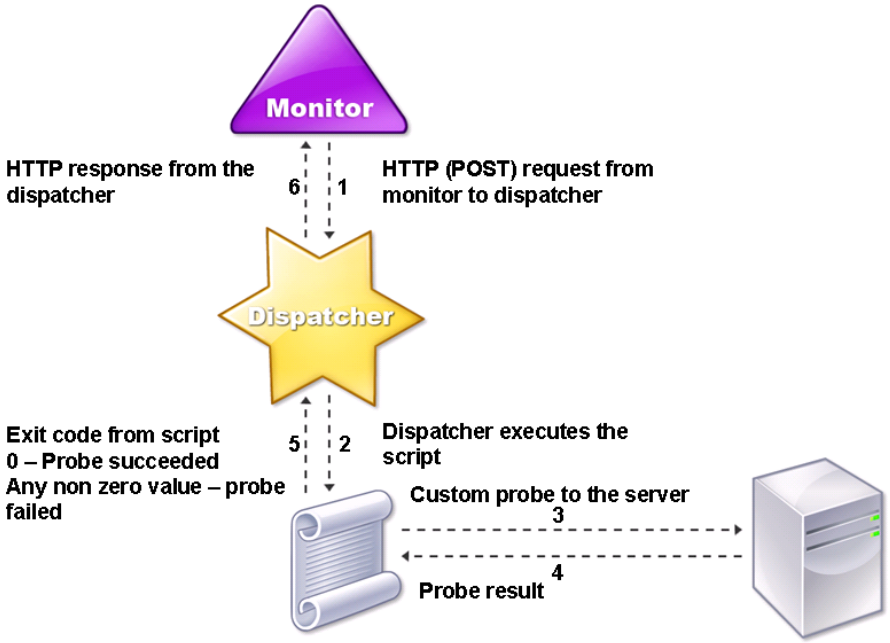
To configure HTTP-inline monitors by using CLI

Type the following command:

```
add lb monitor <monitorName> <type> -respCode <int[-int]> -httpRequest
    <string> -resptimeout <integer> [<units>] -retries <integer> -
    downTime <integer> [<units>] -action <action>
```

Example:

```
add lb monitor http_inline HTTP-INLINE -respCode 200 304 -httpRequest "
    HEAD /var/static/empty.htm" -resptimeout 4 -retries 1 -downTime 2 -
    action NONE
```



Understand user monitors

August 11, 2023

User monitors extend the scope of custom monitors. You can create user monitors to track the health of customized applications and protocols that the Citrix ADC appliance does not support. The following diagram illustrates how a user monitor works.

Figure 1. User Monitors

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

A user monitor requires the following components.

- **Dispatcher.** A process, on the appliance, that listens to monitoring requests. A dispatcher can be on the loopback IP address (127.0.0.1) and port 3013. Dispatchers are also known as internal dispatchers. A dispatcher can also be a web server that supports the Common Gateway Interface (CGI). Such dispatchers are also known as external dispatchers. They are used for custom scripts that do not run on the FreeBSD environment, such as .NET scripts.

> **Note:**
>
> You can configure the monitor and the dispatcher to use HTTPS instead of HTTP by enabling the "secure"option on the monitor, and configure it as an external dispatcher. However, an internal dispatcher understands only HTTP, and cannot use HTTPS.

```
1 In a HA setup, the dispatcher runs on both the primary and secondary
    Citrix ADC appliances. The dispatcher remains inactive on the
    secondary appliance.
```

Script. The script is a program that sends custom probes to the load balanced server and returns the response code to the dispatcher. The script can return any value to the dispatcher, but if a probe succeeds, the script must return a value of zero (0). The dispatcher considers any other value as probe

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

failure.

The Citrix ADC appliance is bundled with sample scripts for commonly used protocols. The scripts exist in the /nsconfig/monitors directory. If you want to add a script, add it there. To customize an existing script, create a copy with a new name and modify it.

Important:

- Starting with Citrix ADC release 13.0 build 41.20, you can use the `nsntlm-lwp.pl` script to create a monitor for monitoring a secure NTLM server.
- Starting with release 10.1 build 122.17, the script files for user monitors are in a new location.

  If you upgrade an MPX or VPX virtual appliance to release 10.1 build 122.17 or later, the changes are as follows:

  - A new directory named conflicts is created in /nsconfig/monitors/ and all the built-in scripts of the previous builds are moved to this directory.
  - All new built-in scripts are available in the /netscaler/monitors/ directory. All custom scripts are available in the /nsconfig/monitors/ directory.
  - Save a new custom script in the /nsconfig/monitors/ directory.
  - After the upgrade is completed, if a custom script is created and saved in the /nsconfig/-monitors/ directory, with the same name as the built-in script, the script in the /netscaler/-monitors/ directory takes priority. The custom script does not run.

  If you provision a virtual appliance with release 10.1 build 122.17 or later, the changes are as follows:

  - All built-in scripts are available in the /netscaler/monitors/ directory.
  - The /nsconfig/monitors/ directory is empty.
  - If you create a custom script, you must save it in the /nsconfig/monitors/ directory.

For the scripts to function correctly:

- The maximum number of characters in the name of the script must not exceed 63.
- The maximum number of script arguments that can be provided to a script must not exceed 512.
- The maximum number of characters that can be provided in the parameter script arguments must not exceed 639.

To debug the script, you must run it by using the nsumon-debug.pl script from the CLI. You use the script name (with its arguments), IP address, and the port as the arguments of the nsumon-debug.pl script. Users must use the script name, IP address, port, time-out, and the script arguments for the nsumon-debug.pl script.

At the CLI, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
nsumon-debug.pl <scriptname> <IP> <port> <timeout> <partitionID> [
    scriptarguments][is_secure]
```

Important: Starting with release 10.5 build 57.x, and 11.0 script files for user monitors support IPv6 addresses and include the following changes:

- For the following protocols, new `pm files` have been included for IPv6 support.
  - RADIUS
  - NNTP
  - POP3
  - SMTP
- The following sample scripts in /netscaler/monitors/ has been updated for IPv6 support:
  - nsbmradius.pl
  - nsldap.pl
  - nsnntp.pl
  - nspop3 nssf.pl
  - nssnmp.pl
  - nswi.pl
  - nstftp.pl
  - nssmtp.pl
  - nsrdp.pl
  - nsntlm-lwp.pl
  - nsftp.pl
  - nsappc.pl

  After upgrading to release 10.5 build 57.x, or 11.0, if you want to use your existing custom scripts with IPv6 services, make sure that you update the existing custom scripts with the changes provided in the updated sample scripts in /netscaler/monitors/.

> **Note:**
>
> The sample script nsmysql.pl does not support the IPv6 address. If an IPv6 service is bound to a user monitor that uses nsmysql.pl, the probe fails.

- The following LB monitor types have been updated to support IPv6 addresses:
  - USER

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- SMTP
- NNTP
- LDAP
- SNMP
- POP3
- FTP_EXTENDED
- StoreFront
- APPC
- CITRIX_WI_EXTENDED

If you are creating a custom script that uses one of these LB monitors types, ensure to include IPv6 support in the custom script. Refer to the associated sample script in /netscaler/monitors/ for the changes that you have to make in the custom script for IPv6 support.

To track the status of the server, the monitor sends an HTTP POST request to the configured dispatcher. This POST request contains the IP address and port of the server, and the script that must be run. The dispatcher runs the script as a child process, with user-defined parameters (if any). Then, the script sends a probe to the server. The script sends the status of the probe (response code) to the dispatcher. The dispatcher converts the response code to an HTTP response and sends it to the monitor. Based on the HTTP response, the monitor marks the service as up or down.

The Citrix ADC appliance logs the error messages to the /var/nslog/nsumond.log file when user monitor probes fail. These detailed error messages are displayed in the GUI, and in the CLI for the `show service`/`service group` commands.

The following table lists the user monitors and the possible reasons for failure.

User monitor type	Probe failure reasons
SMTP	Monitor fails to establish a connection to the server.
NNTP	Monitor fails to establish a connection to the server. Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Monitor fails to find the NNTP group.
LDAP	Monitor fails to establish a connection to the server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

User monitor type	Probe failure reasons
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Monitor fails to bind to the LDAP server.
	Monitor fails to locate an entry for the target entity in the LDAP server.
FTP	The connection to the server times out.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Logon fails.
	Monitor fails to find the file on the server.
POP3	Monitor fails to establish a connection to the database. Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Logon fails.
	Preparation of the SQL query fails.
	Execution of the SQL query fails.
SNMP	Monitor fails to establish a connection to the database. Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Logon fails.
	Monitor fails to create the SNMP session.
	Monitor fails to find the object identifier.
	The monitor threshold value setting is greater than or equal to the actual threshold of the monitor.
RDP (Windows Terminal Server)	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

User monitor type	Probe failure reasons
	Monitor fails to create a socket.
	Mismatch in versions.
	Monitor fails to confirm connection.

You can view the log file from the CLI by using the following commands:

```
> shell
root@ns# cat /var/nslog/nsumond.log
root@ns# exit
>
```

The command opens a BSD shell, displays the log file on the screen, closes the BSD shell, and returns you to the CLI.

Before Citrix ADC release 13.0 build 52.X, the `show service/service group` command displayed a generic error message saying "probe failed"as the cause for the user monitor probe failure.

Example:

```
show service ftp

Monitor Name: mon2
State: UNKNOWN  Weight: 1   Passive: 0
Probes: 3    Failed [Total: 0 Current: 0]
Last response: Failure - Probe failed.
Response Time: 1071.838 millisec
```

From Citrix ADC release 13.0 build 52.X onwards, the `show service/service group` command displays the actual cause for the user monitor probe failure.

Example:

```
show service ftp

Monitor Name: mon2
State: DOWN   Weight: 1   Passive: 0
Probes: 729   Failed [Total: 726 Current: 726]
Last response: Failure - Login failed.
Response Time: 8000.0 millisec
```

User monitors also have a time-out value and a retry count for probe failures. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.

Example1:

```
add lb monitor <name> USER –scriptname <script-name> -resptimeout 5
    seconds
```

> **Note:**
>
> For scriptable monitors, the response timeout must be configured to a value equal to the expected timeout + 1 second. For example, if you expect the timeout to be 4 seconds, configure the response timeout as 5 seconds.

Example2:

```
add lb monitor <name> USER –scriptname <script-name> -scriptargs <
    Arguments> -secureargs <Arguments>
```

> **Note:**
>
> We recommend that you use the `secureargs` parameter instead of the `scriptargs` parameter for any sensitive data that is related to the scripts.

How to use a user monitor to check websites

September 14, 2021

You can configure a user monitor to check for specific website problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

HTTP response code	Meaning
200 - success	Probe success.
503 - service unavailable	Probe failure.
404 - not found	Script not found or cannot run.
500 - Internal server error	Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN.

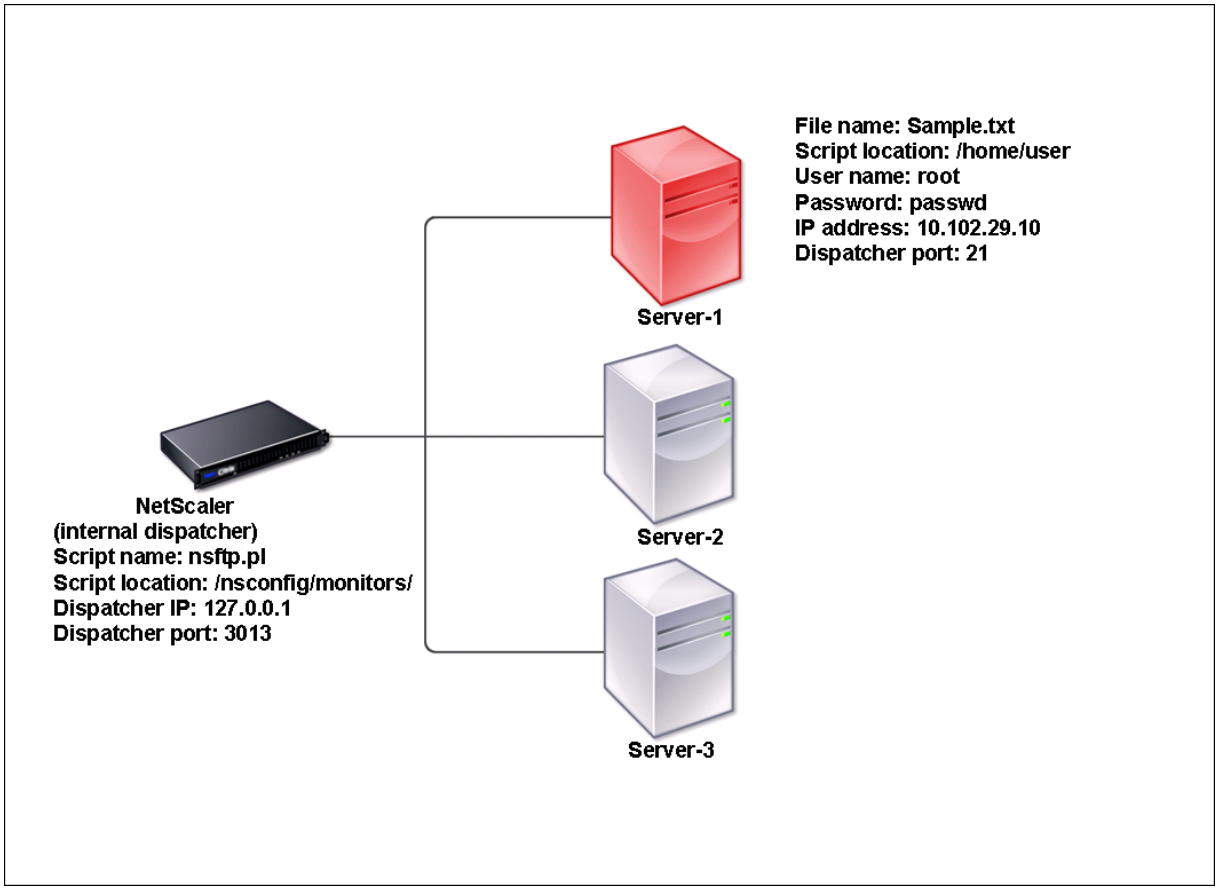
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

HTTP response code	Meaning
400 - bad request	Error parsing HTTP request.
502 - bad gateway	Error decoding script's response.

You configure the user monitor for HTTP by using the following parameters.

Parameter	Specifies
scriptName	The path and name of the script to run.
scriptArgs	The strings that are added in the POST data. They are copied to the request verbatim.
dispatcherIP	The IP address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.
localfileName	The name of a monitor script file on the local system.
destPath	A particular location on the Citrix ADC appliance where the uploaded local file is stored.

To create a user monitor to monitor HTTP, see Configuring Monitors in a Load Balancing Setup.



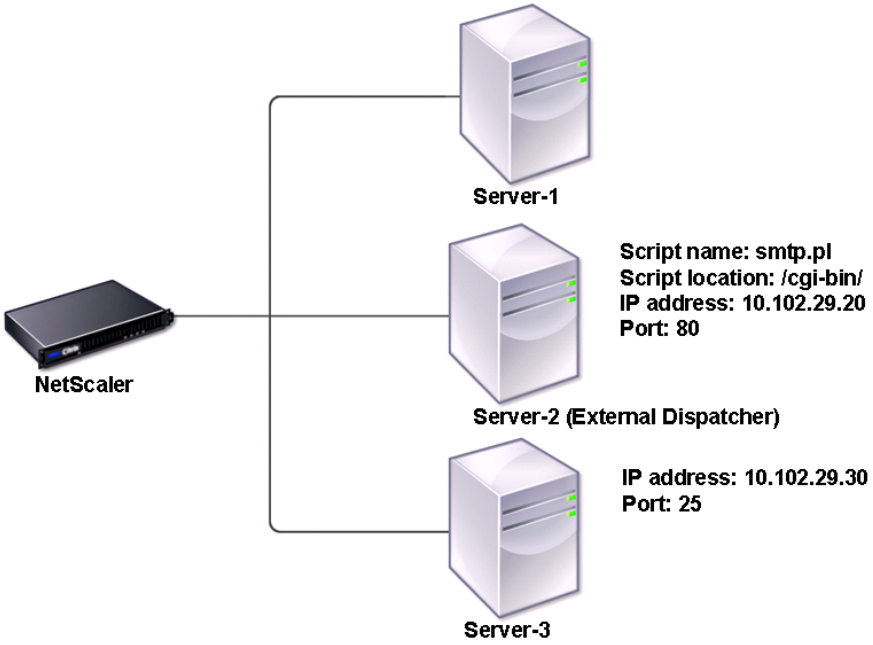
Understand the internal dispatcher

September 14, 2021

You can use a custom user monitor with the internal dispatcher. Consider a case where you need to track the health of a server based on the presence of a file on the server. The following diagram illustrates this scenario.

Figure 1. Using a user monitor with the internal dispatcher

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



A possible solution is to use a Perl script that initiates an FTP session with the server and checks for the presence of the file. You can then create a user monitor that uses the Perl script. The Citrix ADC appliance includes such a Perl script (nsftp.pl), in the /nsconfig/monitors/ directory.

You can use a user monitor with an external dispatcher. Consider a case where you must track the health of a server based on the state of an SMTP service on another server. This scenario is illustrated in the following diagram.

Figure 2. Using a user monitor with an external dispatcher

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

A possible solution would be to create a Perl script that checks the state of the SMTP service on the server. You can then create a user monitor that uses the Perl script.

Configure a user monitor

July 28, 2022

User monitors track the health of custom applications and protocols that a Citrix ADC appliance does not support. This is an extended scope of custom monitors. To configure a user monitor, you must perform the following steps:

- Write a script that can monitor the services bound to it.
- Upload the script to the `/nsconfig/monitors` directory on the Citrix ADC appliance.
- Provide executable permission to the script.

If the monitor type is a protocol that the appliance does not support, only then you must use a monitor of type **USER**. User monitors support only Perl and Bash type scripts. They do not support Python scripts.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note**
>
> Monitor probes originate from the NSIP address. The `scriptargs` configured for the monitor type **USER** is displayed in the running configuration and ns.conf files.

For more information about monitors, see Configure monitors.

To configure a user monitor by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> USER -scriptname <NameOfScript> -
   scriptargs <Arguments> -secureargs <Arguments>
```

Example1:

```
add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file
   =/home/user/
sample.txt;user=root;password=passwd"
```

Example2:

```
add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file
   =/home/user/
sample.txt -secureargs "user=root;password=passwd"
```

> Note
>
> The `secureargs` parameter stores the script arguments in an encrypted format instead of the plain text format. Citrix recommends you use the `secureargs` parameter instead of the scriptargs parameter for any sensitive data that is related to the scripts, for example, user name and password. If you choose to use both the parameters together, the script specified in `-scriptname` must accept the arguments in the order: `<scriptargs> <secureargs>`. Specify the first few arguments in the `<scriptargs>` parameter; and the rest of the arguments in the `<secureargs>` parameter. That is, maintain the order defined for the arguments. Secure arguments are applicable only for the internal dispatcher. If you want to use an external dispatcher, Citrix recommends securing the vulnerable data in your scripts.

Example 3:

Let's say you have already configured the `scriptargs` parameter with the arguments: "a=b;c=d;e=f".

```
add monitor mon1 USER -scriptargs "a=b;c=d;e=f"
```

If you want to use the `secureargs` parameter instead of `scriptargs` parameter, do the following:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Nullify the `scriptargs` parameter.
- Provide all the arguments under `secureargs` parameter.

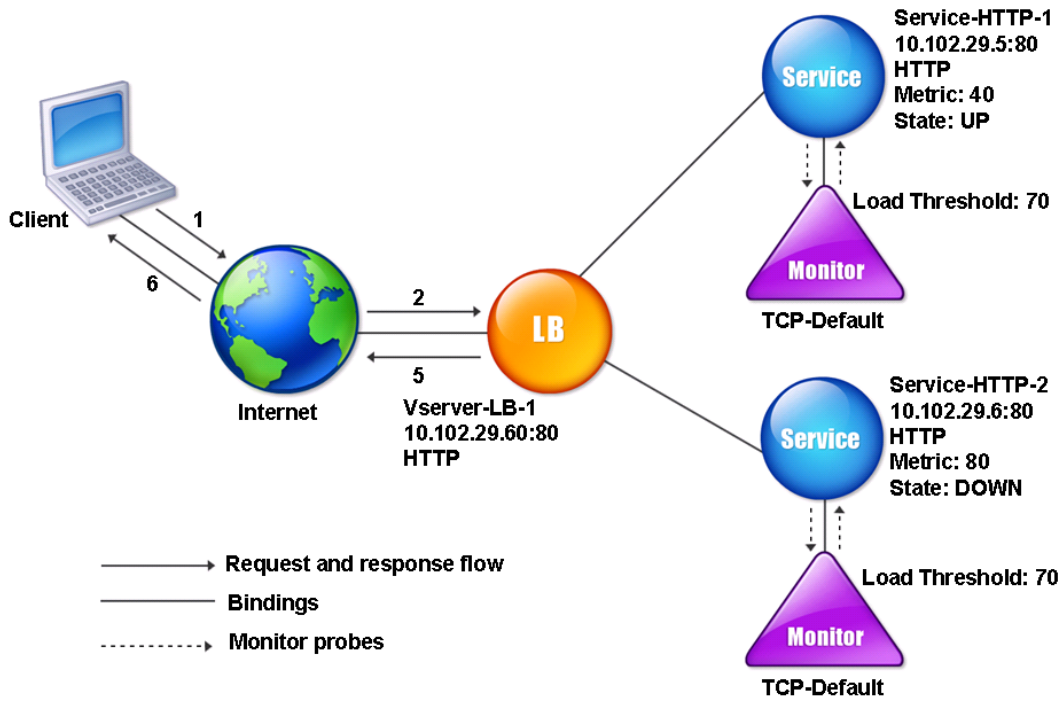
```
set monitor mon1 USER -scriptargs "" -secureargs "a=b;c=d;e=f"
```

To configure a user monitor by using the GUI

1. Navigate to **Traffic Management> Load Balancing> Monitors**, click **Add**.
2. In the **Create monitor** page, do the following:
   - Select the monitor type as **USER**.
   - Choose the script from the drop-down menu or upload your own script.
   - Enter appropriate values for the **Script Arguments** and **Secure Arguments** fields.
   - Click **Create**.

   A user monitor is created.

Understand load monitors



September 14, 2021

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The Citrix ADC appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in Setting Up Basic Load Balancing.

Figure 1. Operation of Load Monitors

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These metrics cannot be changed.
- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL
- FOUNDRY
- ALTEON

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

You can either add the appliance-generated metric tables, or you can add tables of your own choosing, as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

Metric name	OIDs	Weight	Threshold
CPU	1.2.3.4	2	70
Memory	4.5.6.7	3	80
Connections	5.6.7.8	4	90

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.

Configure load monitors

February 27, 2023

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see Creating Monitors. Next, select, or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

To create a metric table by using the command line interface

At the command prompt, type the following commands:

```
add lb metricTable <metricTableName>

bind lb metricTable <metricTableName> <metric> <SNMPOID>
```

Example:

```
add lb metricTable Table-Custom-1

bind lb metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To create a metric table and bind metrics to it by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Metric Tables** and create a metric table.
2. To bind metrics, click **Bind** and specify a metric and an SNMP OID.

Unbind metrics from a metrics table

September 14, 2021

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

To unbind metrics from a metric table by using the command line interface

At the command prompt, type:

```
unbind lb metricTable <metricTable> <metric>
```

Example:

```
unbind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5
```

To unbind metrics from a metric table by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Metric Tables**.
2. Open a metric table, select a metric, and click **Delete**.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.

Configure reverse monitoring for a service

September 14, 2021

A reverse monitor marks a service as DOWN if the probe criteria are satisfied and UP if they are not satisfied. For example, if you want a backup service to receive traffic only when the primary service is DOWN, you can bind a reverse monitor to the secondary service but configure it to probe the primary service.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The Citrix ADC appliance supports the following reverse monitors:

- HTTP
- ICMP
- TCP (from release 11.1 build 49.x)

Configuring HTTP Reverse Monitoring for a Service

The following table describes the conditions of HTTP direct and reverse monitoring for a service:

Condition	Direct	Reverse
Connection not established.	Fail	Fail
HTTP response code matches the probe's specifications.	Success	Fail
HTTP response code does not match the probe's specifications.	Fail	Success
Probe timed out.	Fail	Fail

To configure HTTP reverse monitoring for a service by using the CLI

At the command prompt, type:

```
add lb monitor <Monitor_Name> HTTP -respCode 200 -httpRequest "HEAD /"
   -destIP <Primary_Service_IP_Address> -destPort 80 -reverse YES

bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
```

Configuring ICMP Reverse Monitoring for a Service

The following table describes the conditions of ICMP direct and reverse monitoring for a service:

Condition	Direct	Reverse
ICMP echo reply is received.	Success	Fail
Probe timed out.	Fail	Success

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure ICMP reverse monitoring for a service by using the CLI

At the command prompt, type:

```
add lb monitor <Monitor_Name> PING -destIP <Primary_Service_IP_Address>
    -reverse YES

bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
```

Configuring TCP Reverse Monitoring for a Service

If a direct TCP monitor receives a RESET in response to a monitor probe, the service is marked DOWN. However, if a reverse TCP monitor receives a RESET response, the probe is considered successful, and the service is marked UP.

The following table describes the conditions of TCP reverse monitoring for a service:

Condition	Direct	Reverse
TCP connection is established.	Success	Fail
Probe timed out.	Fail	Fail
Response to probe is RESET.	Fail	Success

To configure TCP reverse monitoring for a service by using the CLI

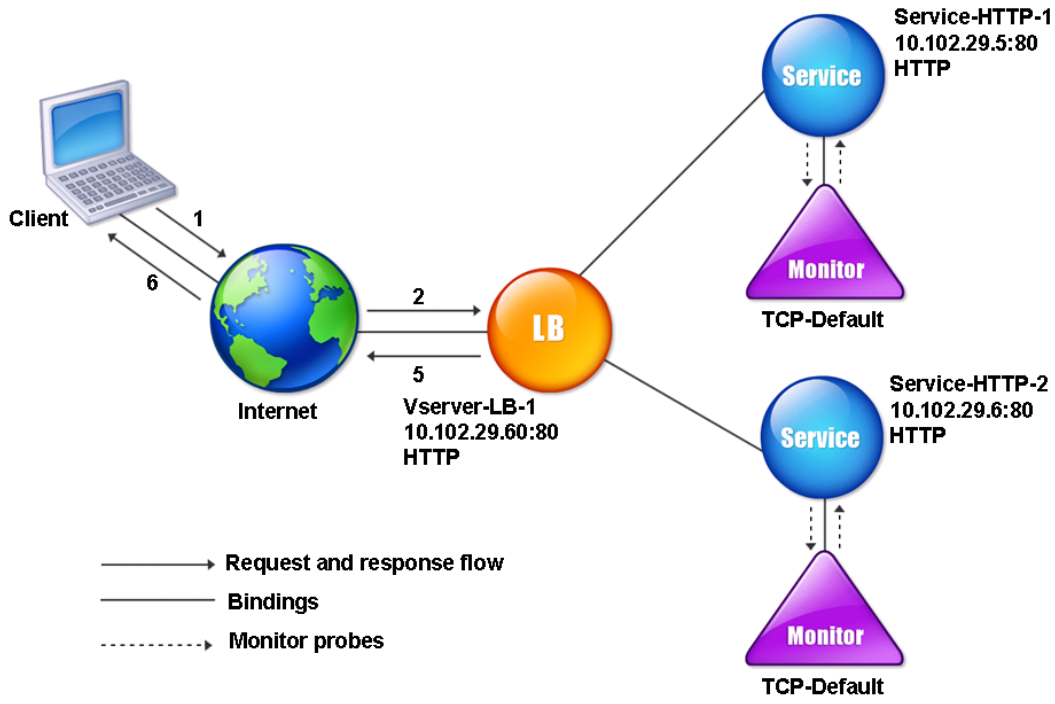
At the command prompt, type:

```
add lb monitor <Monitor_Name> TCP –destip <Primary_Service_IP_Address>
    -destport <primary_service_port> –reverse YES

bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
```

To configure reverse monitoring by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**.
2. Create an HTTP, ICMP, or TCP monitor and select **Reverse**.



Configure monitors in a load balancing setup

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure monitors on a website, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. For more information about creating custom monitors, see Custom Monitors. Once you have chosen or created a monitor, you then bind it to the appropriate service. The monitor names can be up to 255 characters in length. The following conceptual diagram illustrates a basic load balancing setup with monitors.

Figure 1. How monitors operate

As shown, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the load balanced server fails to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.

- Closing Monitor Connections
- Ignoring the Upper Limit on Client Connections for Monitor Probes

Create monitors

October 16, 2023

The Citrix ADC appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

To create a monitor by using the CLI

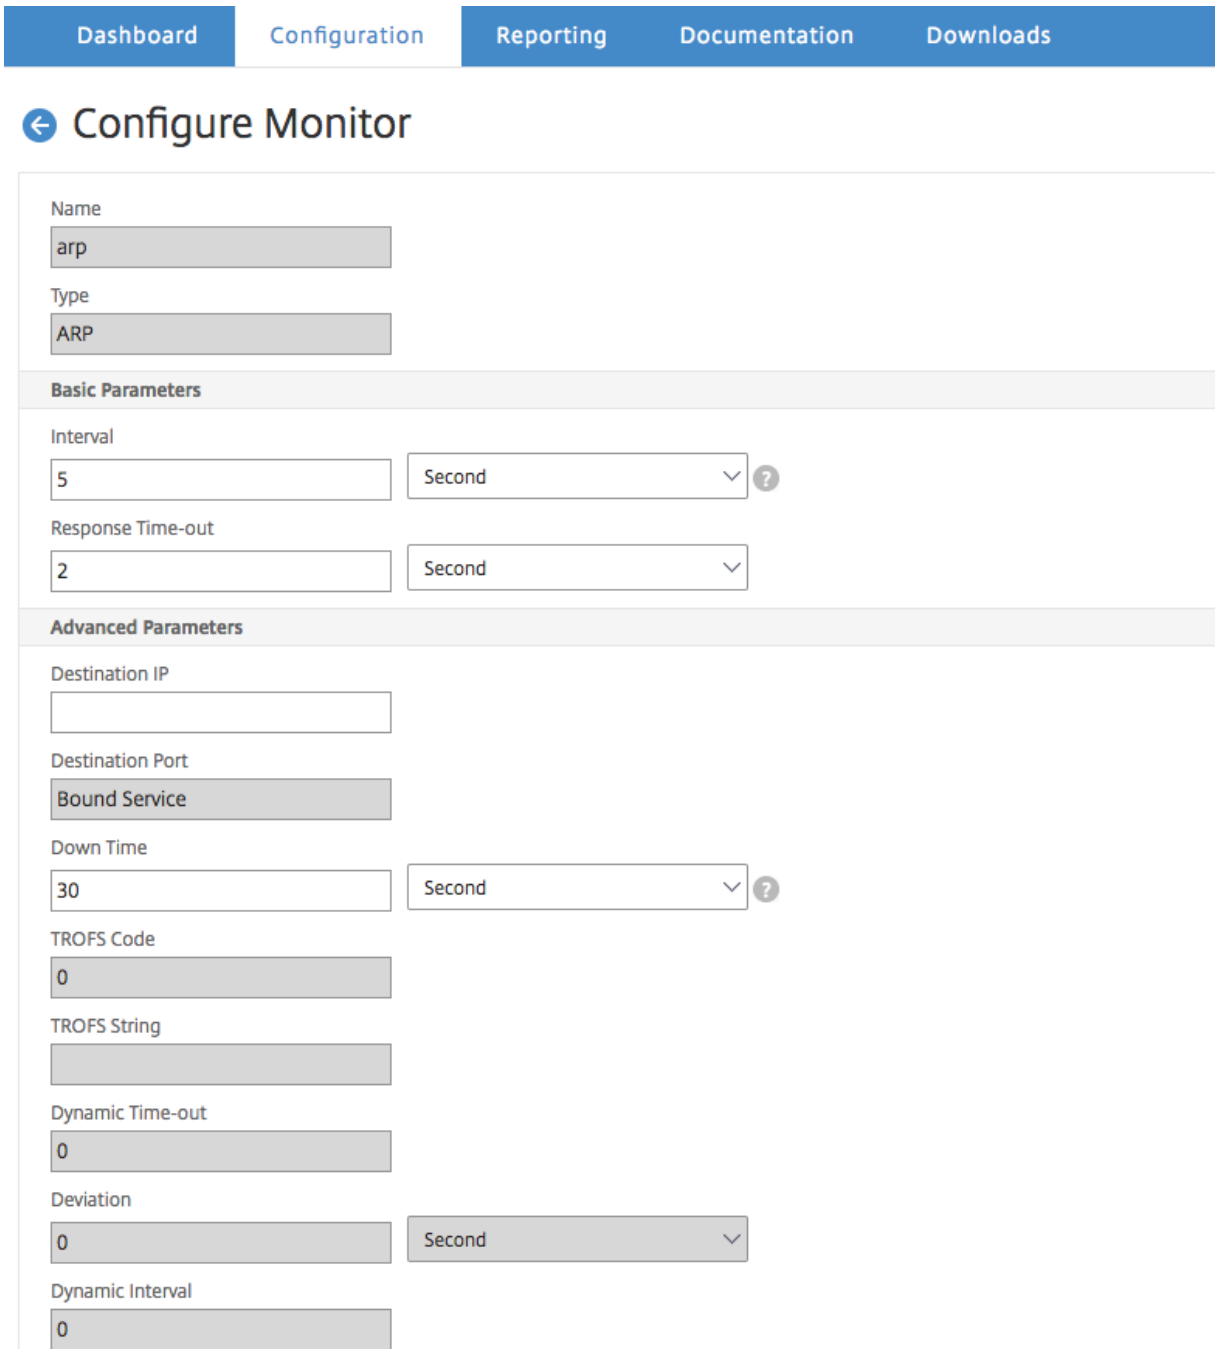
At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> [<interval>]

add lb mon monitor-HTTP-1 HTTP

add lb mon monitor-HTTP-2 TCP 2
```

To create a monitor by using the GUI



1. Navigate to **Traffic Management**> **Load Balancing**> **Monitors**.
2. Click **Add** and create a monitor type that meets your requirement.

The Create Monitor screen contains two sections, **Basic Parameters** and **Advanced Parameters**.

Depending on the monitor type, the **Basic Parameters** section contains the parameters that must be set for each monitor. The **Advanced Parameters** section contains the parameters that can be used in advanced use cases.

The following figure is a sample of a Create Monitor page of the ARP monitor type.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note

Prior to NetScaler release 12.0 build 56.20, Basic Parameters and Advanced Parameters are named Standard Parameters and Special Parameters respectively.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure monitor parameters to determine the service health

September 14, 2021

You can configure the following monitoring parameters to mark a service as DOWN based on the monitoring probes.

Retries

Maximum number of probes to send to establish the state of a service for which a monitoring probe fails.

failureRetries

Number of retries that must fail, out of the number specified for the Retries parameter, for a service to be marked as DOWN. For example, if the Retries parameter is set to 10 and the Failure Retries parameter is set to 6, out of the 10 probes sent, at least six probes must fail if the service is to be marked as DOWN.

alertRetries

Number of consecutive probe failures after which the appliance generates an SNMP trap called monProbeFailed.

Setting alertRetries to a value higher than the Retries value

The alertRetries parameter, which specifies the maximum number of consecutive monitoring-probe failures after which the Citrix ADC appliance generates an SNMP trap called monProbeFailed, can now be set to a value higher than the Retries value (which specifies the maximum number of probes to send to establish the state of a service for which a monitoring probe failed). If the alertRetries value is higher than the Retries value, the SNMP trap is not sent until after the service is DOWN.

For example, if you set Retries to 3, alertRetries to 12, and the time interval to 5 seconds, the service is marked DOWN after 15 seconds (3*5), but no alert is generated. If the monitor probes are still failing after 60 seconds (12*5), the Citrix ADC appliance generates a monProbeFailed trap. If a probe succeeds at some time between 15 and 60 seconds, the service is marked UP and no alert is generated.

Setting the alertRetries value to a value higher than the Retries value helps in generating only genuine alerts and avoid false positives during scheduled restarts.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set the alertRetries parameter value to a higher value than the Retries value by using the command line interface At the command prompt, type:

```
add lb monitor <monitorName> [-retries <integer>] [-alertRetries <
    integer>]
```

Example:

add lb monitor monitor-HTTP-1 HTTP -retries 3 -alertRetries 12

To set the alertRetries parameter value to a higher value than the Retries value by using the GUI

1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Monitors**.
2. Click **Add** to add a new monitor or select an existing monitor and click **Edit**.
3. In the **Retries** box, type the value for the Retries parameter.
4. In the **SNMP Alert Retries** box, type the value for the `alertRetries` parameter.

Bind monitors to services

September 14, 2021

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN.

If you bind multiple monitors to a service, the Citrix ADC appliance checks the state of all the monitors and then decides the state of the service. You can configure different weights to a monitor. The weight of a monitor specifies how much that monitor contributes to designating the service as UP or DOWN. A monitor with a greater weight has a higher preference in marking the service UP or DOWN. Default weight is 1. Therefore, even if one of the monitors fails, the service is marked as DOWN. For more information, see Set a threshold value for the monitors bound to a service.

Note: The destination IP address of a monitor probe can be different than the server IP address and port.

To bind a monitor to a service by using the CLI

At the command prompt, type:

```
bind service <name> (-monitorName <string>)
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
bind service s1 -monitorName tcp
```

To bind a monitor to a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open the service, and add a monitor.

Modify monitors

September 14, 2021

You can modify the settings for any monitor that you created.

Note: Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

To modify an existing monitor by using the CLI

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <interval> -resptimeout <
    resptimeout>
```

Example:

```
set mon monitor-HTTP-1 HTTP -interval 50 milli
-resptimeout 20 milli
```

To modify an existing monitor by using the GUI

Navigate to **Traffic Management > Load Balancing > Monitors**, and open a monitor to modify.

Enable and disable monitors

September 17, 2024

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

To enable a monitor by using the CLI

At the command prompt, type:

```
set lb monitor <monitor_name> <type> -state ENABLED
```

Example:

```
set lb monitor monitor-1 http -state ENABLED
```

To enable a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and from the Action list, select Enable.

To disable a monitor by using the CLI

At the command prompt, type:

```
set lb monitor <monitor_name> <type> -state DISABLED
```

Example:

```
set lb monitor monitor-1 http -state DISABLED
```

Unbind monitors

September 14, 2021

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

To unbind a monitor from a service by using the CLI

At the command prompt, type:

```
unbind lb monitor <monitorName>
```

Example:

```
unbind mon monitor-HTTP-1 Service-HTTP-1
```

To unbind a monitor from a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service to modify.
2. Click in the Monitors section, select a monitor, and click **Unbind**.

Remove monitors

September 14, 2021

After you unbind a monitor that you created from its service, you can remove that monitor from the Citrix ADC configuration. (If a monitor is bound to a service, it cannot be removed.)

Note: When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

To remove a monitor by using the CLI

At the command prompt, type:

```
rm lb monitor <monitorName> <type>
```

Example:

```
rm lb monitor monitor-HTTP-1 HTTP
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To remove a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and click **Delete**.

View monitors

September 14, 2021

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your Citrix ADC configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

To view monitor bindings by using the CLI

At the command prompt, type:

```
show lb monbindings <MonitorName>
```

Example:

```
show lb monbindings monitor-HTTP-1
```

To view monitor bindings by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and in the Action list, click **Show Bindings**.

To view monitors by using the CLI

At the command prompt, type:

```
show lb monitor <monitorName>
```

Example:

```
show lb mon monitor-HTTP-1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To view monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**. The details of the available monitors appear in the Monitors pane.

Close monitor connections

September 14, 2021

The Citrix ADC appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the appliance and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and might not be always necessary.

For the TCP type monitor, you can configure the appliance to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor-probe connection to go through the complete procedure, set the value to FIN.

Note: The monitorConnectionClose setting is applicable only for type TCP and TCP-Default monitors.

To configure monitor-connection closure by using the command line interface:

At the command prompt, type:

```
set lb parameter -monitorConnectionClose <monitor_conn_close_option>
```

Example

```
set lb parameter -monitorConnectionClose RESET
```

To configure monitor-connection closure by using the configuration utility:

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**.
2. Select **FIN** or **Reset**.

Closing Monitor Connections at the Service or Service Group Level

You can also configure the appliance to close a monitor-probe connection at the service and service group level by setting the monConnectionClose parameter. If this parameter is not set, the monitor connection is closed by using the value set in the global load balancing parameters. If this parameter is set at the service or service group level, the monitor connection is closed by sending a connection termination message, with the FIN or RESET bit set, to the service or service group.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure monitor-connection closure at the service level by using the CLI

At the command prompt, type:

```
set service <service_name> -monConnectionClose ( RESET | FIN )
```

To configure monitor-connection closure at the service group level by using the CLI

At the command prompt, type:

```
set serviceGroup <service_name> -monConnectionClose ( RESET | FIN )
```

To configure monitor-connection closure at the service level by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Add or edit a service, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

To configure monitor-connection closure at the service group level by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Add or edit a service group, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

> **Note:** For closing a monitor-probe connection using global load balancing parameters, you can configure monitorConnectionClose to FIN or RESET. When you configure the monitorConnectionClose parameter to;
>
> - FIN: The appliance performs a complete TCP handshake.
> - RESET: The appliance closes the connection after receiving the SYN-ACK from the service.
>
> In the lighter version of Citrix ADC CPX, the monitorConnectionClose parameter value is set to RESET by default and cannot be changed to FIN at the global level. However, you can change the monitorConnectionClose parameter to FIN at the service level.

Ignore the upper limit on client connections for monitor probes

September 14, 2021

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service,

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

the Citrix ADC appliance stops sending requests to the service when the threshold is reached and resumes sending connections to the service after the number of existing connections falls to within the limits. You can configure the appliance to skip this check when it sends monitor-probe connections to a service.

Note: You cannot skip the maximum-client-connections check for an individual service. If you specify this option, it applies to all the monitors bound to all the services configured on the Citrix ADC appliance.

To set the Skip MaxClients for Monitor Connections option by using the CLI

At the command prompt, type:

```
set lb parameter -monitorSkipMaxClient (ENABLED|DISABLED)
```

Example:

```
set lb parameter -monitorSkipMaxClient enabled
```

To set the Skip MaxClients for Monitor Connections option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**.
2. Select **Skip MaxClients for Monitoring Connections**.

Manage a large scale deployment

September 14, 2021

The Citrix ADC appliance contains several features that are helpful when you are configuring a large load balancing deployment. Instead of configuring virtual servers and services individually, you can create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure. This significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services. You can then make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Ranges of virtual servers and services

September 14, 2021

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

  For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this example, five virtual servers are created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

  Note: The IP addresses of the virtual servers and services must be consecutive.

- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.

  For example, if you have three virtual servers named `Vserver-x`, `Vserver-y`, and `Vserver-z`, instead of configuring them separately, you can type `vserver [x-z]` to configure them all.

Creating a range of virtual servers

To create range of virtual servers by using the CLI

At the command prompt, type one of the following commands:

```
add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<port>]

add lb vserver <name>@[<rangeValue>]> <protocol> <IPAddress[<rangeValue>]> [<port>]
```

Example:

```
add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

OR

```
add lb vserver vserver[P-R] http 10.102.29.[26-28] 80

vserver "vserverP" added

vserver "vserverQ" added

vserver "vserverR" added

Done
```

To create range of virtual servers by using the CLI

At the command prompt, type one of the following commands:

```
add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<
    port>]

add lb vserver <name>@**[**<rangeValue>**]**> <protocol> <IPAddress[<
    rangeValue>]> [<port>]
```

Example:

```
add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
```

OR

```
add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
vserver "vserverP" added
vserver "vserverQ" added
vserver "vserverR" added
Done
```

To create range of virtual servers by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Add a virtual server, and specify a range.

Creating a range of services

If you specify a range for the service name, specify a range for the IP address too.

To create range of services by using the CLI

At the command prompt, type the command:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add service <name>@ <IP>@ <protocol> <port>
```

Example:

```
> add service serv[1-3] 10.102.29.[102-104] http 80
service "serv1" added
service "serv2" added
service "serv3" added
 Done
```

Configure service groups

September 14, 2021

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring, or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

The members of a service group are identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not reconfigure the member on the Citrix ADC appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the appliance learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

Note: If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the Citrix ADC appliance. A domain name is resolved into an IP address only if the corresponding address record is present on the appliance or the name server.

Create service groups

You can configure up to 8192 service groups on the Citrix ADC appliance.

To create a service group by using the command line

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add servicegroup <ServiceGroupName> <Protocol>
```

Example:

```
add servicegroup Service-Group-1 HTTP
```

To create a service group by using the configuration utility

Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**, and add a service group.

Bind a service group to a virtual server

When you bind a service group to a virtual server, the member services are bound to the virtual server.

To bind a service group to a virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name>@ <serviceGroupName>
```

Example:

```
bind lb vserver Vserver-LB-1 Service-Group-1
```

To bind a service group to a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Service Groups**.

Bind a member to a service group

Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

In the GUI, if you want to add a domain-name based service group member, select **Server Based**.

With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

```
bind servicegroup <serviceGroupName> (<IP>@ | <serverName>) <port>
```

Examples:

```
bind servicegroup Service-Group-1 10.102.29.30 80

bind servicegroup Service-Group-2 1000:0000:0000:0000:0005:0600:700a
    :888b 80

bind servicegroup CitrixEdu s1.citrite.net
```

To add members to a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups** and open a service group.
2. Click in the Service Group section, and do one of the following:
   - To add an IP based service group member, select IP Based.
   - To add a server-name based service group member, select Server Based.

   If you want to add a domain-name based service group member, select **Server Based**. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.
3. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box

   Note: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and then click Add.
4. Click Create.

Bind a monitor to a service group

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To bind a monitor to a service group by using the command line interface

At the command prompt, type:

```
bind serviceGroup <serviceGroupName> -monitorName <string> -monState (
    ENABLED | DISABLED)
```

Example:

```
bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
```

To a bind monitor to a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Open a service group and, in Advanced Settings, click **Monitors**.

Retain the original state of a service group member after disabling and enabling a virtual server

From build 64.x, a new global option, –retainDisableServer, enables you to retain a service-group member's state when a server is disabled and reenabled.

Previously, a member's state would change from DISABLED to ENABLED under the following set of conditions:

- Two applications are deployed on the same port on a virtual server.
- Two service groups with a common member are bound to this virtual server, and the common member is enabled in one group and disabled in the other.
- The server is disabled and then reenabled.

Under these conditions, disabling the server disables all the service group members, and reenabling the server enables all the members, by default, regardless of their earlier states. To bring the members back to the original states, you must manually disable those members in the service group. This is a cumbersome task and prone to errors.

Manage service groups

September 14, 2021

You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group. For more information about service groups, see Configure service groups.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Modify a service group

You can modify the attributes of service group members. You can set several attributes of the service group, such as maximum client, Sure Connect, and compression. The attributes are set on the individual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

Note: A parameter you set for a service group is applied to the member servers in the group, not to individual services.

To modify a service group by using the command line interface

At the command prompt, type the following command with one or more of the optional parameters:

```
set servicegroup <serviceGroupName> [-type <type>] [-maxClient <
    maxClient>] [-maxReq <maxReq>] [-cacheable (YES|NO)] [-cip (ENABLED|
    DISABLED)] [-cipHeader <cipHeader>] [-usip (YES|NO)] [-sc (ON|OFF)]
    [-sp (ON|OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>]
     [-cka (YES|NO)] [-TCPB (YES|NO)] [-CMP (**YES**|**NO**)] [-
    maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state
    (ENABLED|DISABLED)] [-downStateFlush (ENABLED|DISABLED)
```

Example:

```
set servicegroup Service-Group-1 -type TRANSPARENT

set servicegroup Service-Group-1 -maxClient 4096

set servicegroup Service-Group-1 -maxReq 16384

set servicegroup Service-Group-1 -cacheable YES
```

To modify a service group by using the configuration utility

Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**, and open the service group to modify.

Remove a service group

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To remove a service group by using the command line interface

At the command prompt, type:

```
rm servicegroup <ServiceGroupName>
```

Example:

```
rm servicegroup Service-Group-1
```

To remove a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and click **Delete**.

Unbind a member from a service group

When you unbind a member from the service group, the attributes set on the service group no longer apply to the member that you unbound. The member services retain its individual settings, however, and continue to exist on the Citrix ADC appliance.

To unbind members from a service group by using the command line interface

At the command prompt, type:

```
unbind servicegroup <serviceGroupName> <IP>@ [<port>]
```

Example:

```
unbind servicegroup Service-Group-1 10.102.29.30 80
```

To unbind members from a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Open a service group, and click in the Service Group Members section.
3. Select a service group member, and click **Unbind**.

Unbind a service group from a virtual server

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and continue to exist on the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To unbind a service group from a virtual server by using the command line interface

At the command prompt, type:

```
unbind lb vserver <name>@ <ServiceGroupName>
```

Example:

```
unbind lb vserver Vserver-LB-1 Service-Group-1
```

To unbind a service group from a virtual server by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Open the virtual server, and click in the Service Group section.
3. Select the service group, and click **Unbind**.

Unbind monitors from service groups

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

To unbind a monitor from a service group using the command line interface

At the command prompt, type:

```
unbind serviceGroup <serviceGroupName> -monitorName <string>
```

Example:

```
unbind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
```

To unbind a monitor from a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Open a service group, and click in the Monitors section.
3. Select a monitor, and click **Unbind**.

Enable or Disable a service group

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

To disable a service group by using the command line interface

At the command prompt, type:

```
disable servicegroup <ServiceGroupName>
```

Example:

```
disable servicegroup Service-Group-1
```

To disable a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and in the Action list, click **Disable**.

To enable a service group by using the command line interface

At the command prompt, type:

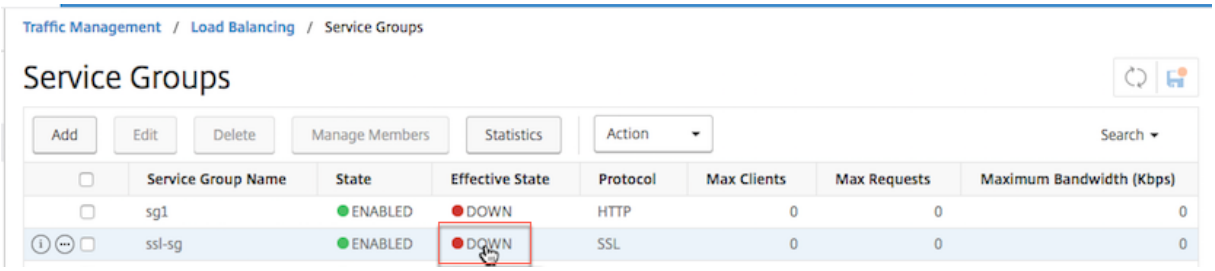
```
enable servicegroup <ServiceGroupName>
```

Example:

```
enable servicegroup Service-Group-1
```

To enable a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and in the Action list, click **Enable**.



View the status of service groups members

Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.

In the Service Groups page, the **Effective State** column displays the status of the service groups. Status UP/DOWN in the **Effective State** column is clickable. You can click the status and get the list of members along with their status in the same view. Select a member and click the **Monitor Details** button to view the reason for the status being DOWN.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: Before NetScaler release 12.0 build 56.20, the status in the **Effective State** column was not clickable.

Viewing the properties of a service group

You can view the following settings of the configured service groups:

- Name
- IP address
- State
- Protocol
- Maximum client connections
- Maximum requests per connection
- Maximum bandwidth
- Monitor threshold

Viewing the details of the configuration can be helpful for troubleshooting your configuration.

To view the properties of a service group by using the command line interface

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

```
show servicegroup <ServiceGroupName>

show servicegroup <ServiceGroupName> -includemembers
```

Example:

```
show servicegroup Service-Group-1
```

To view the properties of a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Click the arrow next to the service group.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Viewing service group statistics

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The Citrix ADC appliance uses the statistics of a service group to balance the load on the services.

To view the statistics of a service group by using the command line interface

At the command prompt, type:

```
stat servicegroup <ServiceGroupName>
```

Example:

```
stat servicegroup Service-Group-1
```

To view the statistics of a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and click **Statistics**.

Load balancing virtual servers bound to a service group

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State
- IP address
- Port

To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

```
show servicegroupbindings <serviceGroupName>
```

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> show servicegroupbindings SVCGRPDTLS
SVCGRPDTLS - State :ENABLED
1) Test-pers (10.10.10.3:80) - State : DOWN
2) BRVSERV (10.10.1.1:80) - State : DOWN
3) OneMore (10.102.29.136:80) - State : DOWN
4) LBVIP1 (10.102.29.66:80) - State : UP
Done
>
```

To display the virtual servers bound to a service group by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Select a service group, and in the Action list, click **Show Bindings**.

Configure a desired set of service group members for a service group in one NITRO API call

October 8, 2023

Support is added to configure a desired set of service group members for a service group in one NITRO API call. A new API, Desired State API, is added to support this configuration. Using Desired State API, you can:

- Provide a list of service group members in a single PUT request on "servicegroup_servicegroupmemberlist_b resource.
- Provide their weight and state (optional) in that PUT request.
- Effectively synchronize the appliance configuration with deployment changes around application servers.

The Citrix ADC appliance compares the requested desired member set with the configured member set. Then, it automatically binds the new members and unbinds the members that are not present in the request.

Note:

- This feature is supported only for service groups of type `API`.
- You can only bind IP address based services using Desired State API, domain name based services are not allowed.
- Previously, only one service group member can be bound in a NITRO call.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Important**
>
> Desired State API for ServiceGroup membership is supported in Citrix ADC cluster deployment.

Use case: Synchronize deployment changes to Citrix ADC appliance in large scale deployments, such as Kubernetes

In large scale and highly dynamic deployments (for example Kubernetes), the challenge is to keep the appliance configuration up-to-date with the rate of change of deployments to accurately serve the application traffic. In such deployments, controllers (Ingress or E-W Controller) are responsible for updating ADC configuration. Whenever there are changes to deployment, `kube-api server` sends the effective set of endpoints through 'Endpoints event'to the controller. The controller uses the Read-Delta-Modify approach where it performs the following:

- Fetches the currently configured endpoint set (service group member set of a service group) for the service from ADC appliance.
- Compares the configured endpoint set with the set in the received event.
- Binds the new endpoints (service group members) or unbinds the deleted endpoints.

Because the rate of change and the size of services is high in this environment, this configuration method is not efficient and might delay configuration updates.

Desired State API solves the problem by accepting the intended member set for a service group in a single API, and effectively updates the configuration.

Create a service group of type API by using the CLI

At the command prompt, type;

```
1 add serviceGroup <serviceGroupName>@ <serviceType> [-autoScale <
     autoScale>]
```

Example:

```
1 add serviceGroup svg1 HTTP -autoScale API
```

You can configure the `autoDisablegraceful` and `autoDisabledelay` and `autoScale` parameters by using add serviceGroup or set serviceGroup command.

```
1 add serviceGroup <serviceGroupName>@ <serviceType> \[-autoScale <
     autoScale>] \[-autoDisablegraceful \( YES | NO)] \[-autoDisabledelay
      <secs>]
2
3 add serviceGroup <serviceGroupName>@ <serviceType> \[-autoScale \(API |
     CLOUD | DISABLED| DNS |POLICY)]
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
4
5 set serviceGroup <serviceGroupName \[-autoDisablegraceful \( YES | NO)]
      \[-autoDisabledelay <secs>]
6
7 set serviceGroup <serviceGroupName \[-autoScale \(API |CLOUD | DISABLED
     | DNS |POLICY)]
```

Example:

```
1 add serviceGroup svg1 HTTP autoDisablegraceful YES -autoDisabledelay
     100
2
3 add serviceGroup svg1 HTTP -autoScale API
4
5 set serviceGroup svg1 -autoDisablegraceful  YES -autoDisabledelay 100
6
7 set serviceGroup svg1 -autoScale API
```

Arguments

autoDisablegraceful Indicates graceful shutdown of the service. If this option is enabled, the appliance waits for all outstanding connections to this service to be closed before deleting the service. For clients that already have a persistent session on the system, new connections or requests continue to be sent to this service. The service member is deleted only if there are no outstanding connections. Default value: NO

autoDisabledelay Indicates the time allowed (in seconds) for a graceful shutdown. During this period new connections or requests continue to be sent to this service for clients that already have a persistent session on the system. Connections or requests from new clients that do not have persistence sessions on the system are not sent to the service. Instead, they are load balanced among other available services. After the delay time expires, the service member is deleted.

Autoscale API Enables using Desired State API for binding the member set to an intended service group. You can set the service group from non-autoscale to Autoscale type of Desired State API, if all provided conditions match.

The set serviceGroup Autoscale command might fail if the existing member bindings meet any of these conditions:

- If the server bound to the service group is either a name server or a domain-based server.
- If the name of the server bound to the service group is an IP address, then it must match the actual server IP address. In the following example, the server name and server IP address do not match.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

  - **CLI:** add server *IP address server name*
  - **Example:** add server 1.2.3.4 4.3.2.1

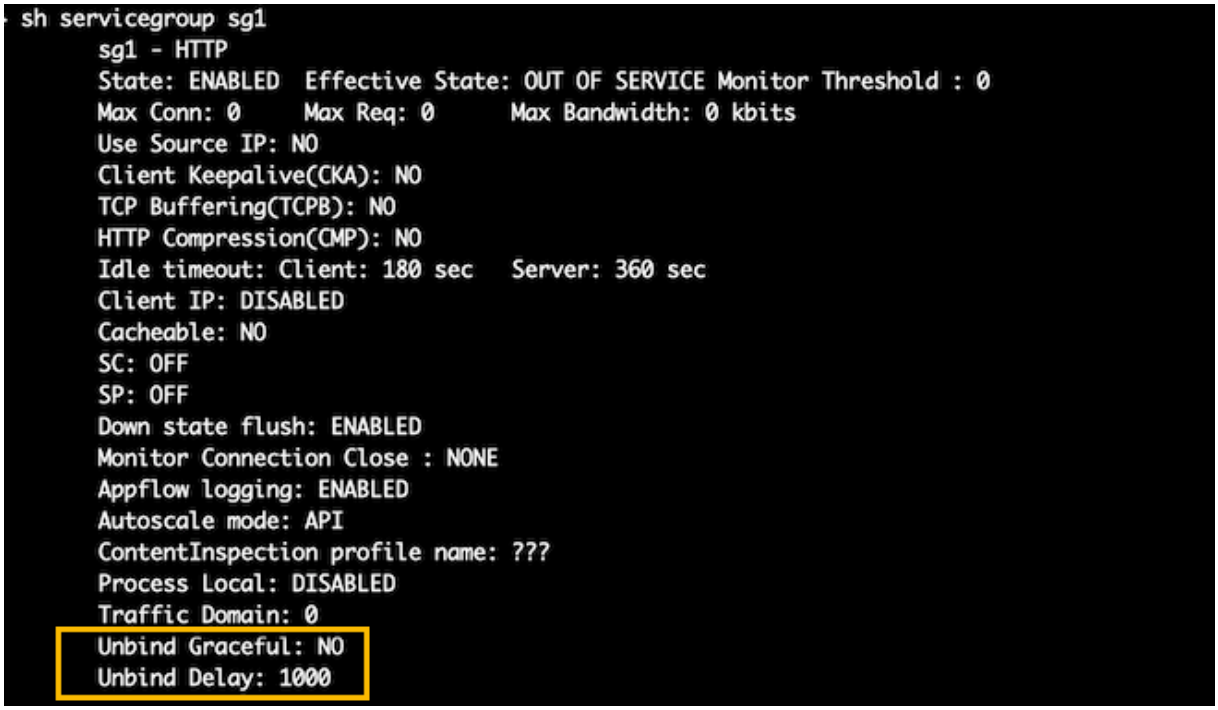
- If the loopback server name is anything other than 127.0.0.1 or 0000:0000:0000:0000:0000:0000:0000:0001.
- If you choose different types of Autoscale (Cloud, API, DNS, and Policy) in a set serviceGroup command and add serviceGroup command.

Important:

- The autoDisablegraceful and autoDisabledelay parameters are applicable only for the service groups of Autoscale type "API"and "CLOUD."
- If the autoDisablegraceful or the autoDisabledelay parameters are not configured, then service members are deleted immediately.

Unbind a service group member gracefully

If any of the service group members is not in the desired state list, those members are gracefully unbound based on the `autoDisablegraceful` or `autoDisabledelay` parameter configuration.



- If one of these parameters is set, then the service group member is unbound gracefully.
- If none of these parameters are set, then the service group member is unbound immediately.

Note:

- Service group members identified for graceful unbind are displayed only when the show service group command is run.
- You cannot perform any operation (such as set, unset) on the service group member identified for graceful unbind.

The following figure displays a sample show service group command.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Create a service group of type API by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**, and click **Add**.
2. In **AutoScale Mode**, select **API**.

Configure graceful shutdown or a time delay for an API type service group by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **AutoScale Mode**, select **API**.
3. In **Auto Disable Graceful**, select **YES**.
4. In **Auto Disable Delay**, enter the wait time for a graceful shutdown.

Note: The **Auto Disable Graceful** or **Auto Display Delay** fields are enabled only if you select **API** or **CLOUD** in **AutoScale Mode**.

Configure automatic domain based service group scaling

October 19, 2022

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records configured for the domain name, on the name server. Even if the name resolution process returns multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a service group, you need to manually bind and unbind other domain based servers to and from the service group, respectively.

However, you can configure a domain based service group to scale automatically based on the complete set of IP addresses returned by a DNS name server for a domain based server. To configure automatic scaling, when binding a domain based server to a service group, enable the automatic scaling option. Following are the steps for configuring a domain based service group that scales automatically:

- Add a name server for resolving domain names. For more information about configuring a name server on the appliance, see Adding a Name Server.
- Add a domain-based server. For information about adding a domain-based server, see Configuring a server object.
- Add a service group and associate the domain based server to the service group, with the Autoscale option set to DNS. For information about adding a service group, see Configuring Service Groups.

When a domain based server is bound to a service group and the automatic scaling option is set on the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name. With the automatic scaling option set, the appliance polls each of the IP addresses by using the default monitor, and then includes in the service group only those IP addresses that are up and available. After the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for domain resolution and includes any new IP addresses in the service group. If an IP address that is part of the service group is not present in the DNS response, the appliance removes that address from the service group after gracefully closing existing connections to the group member, a process during which it does not allow any new connections to be established with the member. If a domain name

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

that resolved successfully in the past results in an NXDOMAIN response, all the service group members associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a service group. You can also bind members with different domain names to a service group with the automatic scaling option set. However, each domain name associated with a service group must be unique within the service group. You must enable the automatic scaling option for each domain based server that you want to use for automatic service group scaling. If an IP address is common to one or more domains, the IP address is added to the service group only once.

> **Important**
>
> - DNS Autoscale is supported in a cluster deployment.
> - Path monitoring for Autoscale service groups is not supported in cluster deployment.

To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

```
add servicegroup <serviceGroupName> <serviceType> -autoscale DNS
```

Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

```
> add serviceGroup servGroup -autoScale YES
 Done
> sh servicegroup servGroup
       servGroup - HTTP
        State: ENABLED  Monitor Threshold : 0
              . . .
              . . .
        1)   192.0.2.31:80   State: UP       Server Name: server1 (Auto
             scale)    Server ID: None Weight: 1

                Monitor Name: tcp-default       State: UP
                Probes: 2       Failed [Total: 0 Current: 0]
                Last response: Success - TCP syn+ack received.

        2)   192.0.2.32:80   State: UP       Server Name: server1 (Auto
             scale)    Server ID: None Weight: 1

                Monitor Name: tcp-default       State: UP
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
17                  Probes: 2       Failed [Total: 0 Current: 0]
18                  Last response: Success - TCP syn+ack received.
19
20          3)   192.0.2.36:80   State: UP       Server Name: server1 (Auto
                 scale)    Server ID: None Weight: 1
21
22                  Monitor Name: tcp-default       State: UP
23                  Probes: 2       Failed [Total: 0 Current: 0]
24                  Last response: Success - TCP syn+ack received.
25
26          4)   192.0.2.55:80   State: UP       Server Name: server1 (Auto
                 scale)    Server ID: None Weight: 1
27
28                  Monitor Name: tcp-default       State: UP
29                  Probes: 2       Failed [Total: 0 Current: 0]
30                  Last response: Success - TCP syn+ack received.
31
32          5)   192.0.2.80:80   State: UP       Server Name: server1 (Auto
                 scale)    Server ID: None Weight: 1
33
34                  Monitor Name: tcp-default       State: UP
35                  Probes: 2       Failed [Total: 0 Current: 0]
36                  Last response: Success - TCP syn+ack received.
37  Done
```

To configure a service group to scale automatically by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Create a service group, and set the Autoscale mode to DNS.

Overwriting TTL values

> **Note:**
>
> This option is supported from Citrix ADC 12.1 build 51.xx and later.

Citrix ADC appliance is configured to periodically query the DNS server for any update in the SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

In case the TTL value is configured both while binding the service group member and also globally, then the TTL value specified while binding the service group member takes precedence.
If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```
bind serviceGroup <serviceGroupName> (<serverName> [-dbsTTL <secs
   >])
```

Example:

```
bind servicegroup svc_grp_1 web_serv -dbsTTL 10
```

- To overwrite the TTL value globally, at the command prompt, type:

```
set lb parameter [-dbsTTL <secs>]
```

Example:

```
set lb parameter -dbsTTL 15
```

Overwriting the TTL values using the GUI

To overwrite the TTL value while binding:

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Domain Based Service TTL**, enter the TTL value.

To overwrite the TTL value at the global level:

1. Navigate to **Traffic Management** > **Load Balancing** > **Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

> **Note:**
>
> If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Specifying different name servers for service group and domain name bindings

> **Note:**
>
> This option is supported from Citrix ADC 12.1 build 51.xx and later.

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a nameserver is not specified while binding a member to the service group, the globally configured nameserver is considered.

Specifying name servers while binding a server to service groups using the CLI At the command prompt, type:

```
bind serviceGroup <serviceGroupName> (<serverName> [-nameServer <
    ip_addr>] [-dbsTTL <secs>])
```

Example:

```
bind servicegroup svc_grp_1 web_serv  -ns.nameserver.com 10.102.27.155
    -dbsTTL 10
```

Specifying name servers while binding a server to service groups using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for the bound domain must be sent.

Service discovery using DNS SRV records

October 8, 2023

An SRV record (service record) is a specification of data in the Domain Name System that defines the location, that is the host name and the port number of servers for specified services. The record also defines the weight and priority of each server.

Example of an SRV record:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

_http._tcp.example.com. 100 IN SRV 10 60 5060 a.example.com.

The following table describes each item in an SRV record:

Service	Protocol	Name	TTL	Class	SRV	Priority	Weight	Port	Target
HTTP	TCP	example.com	100	IN	SRV	10	60	5060	a.example.com

You can use the DNS SRV records to discover the service endpoints. Citrix ADC appliance is configured to periodically query the DNS servers with the SRV record associated with a service. On receiving the SRV record, each of the target host published in the SRV record is bound to a service group associated with the service. Each of the bindings inherits the port, priority, and weight from the SRV record. For each service deployment the user has to configure the Citrix ADC appliance once while bringing it up, thus making it a single touch deployment for applications.

Important: The weight of dynamically learned service group members cannot be modified using the CLI or the GUI.

Use case: Load balancing microservices

Applications are moving toward microservice architecture from monolithic architectures. Movement to microservice architecture along with back-end server autoscale solution, is making application deployment more dynamic. To support such a dynamic deployment, the proxies or ADC must be able to dynamically detect the back-end application or service instances and absorb them into the proxy configuration.
The service discovery using DNS SRV records feature aids configuration of the Citrix ADC appliance in such a dynamic deployment scenario. Application developers can use some of the orchestration platforms to deploy the application. Orchestration platforms while instantiating containers during application deployment, might not assign the protocol specific standard port for each of these containers. In such scenarios, discovering the port information becomes the key to configuring the Citrix ADC appliance. SRV records are helpful in such a scenario. SRV record parameters such as the priority and weight can be used for better load balancing of applications.

- Priority parameter can be used to dictate the priority of the server pool.
- Weight parameter can be used to dictate the capacity of the back-end service instances and hence can be used for weighted load balancing.
- Whenever there is a change in the back-end server pool, for example a back-end instance is removed from the pool, the instance is removed graciously only after all the existing client connections are honored.

> **Note:**
>
> - An A/AAAA records based service discovery, all resolved IP addresses have the same weight

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> because you assign the weight to the domain being resolved.
>
> - If the weight in SRV response is greater than 100, then services are not created.

Priority based load balancing using SRV records

You can use SRV records to perform priority-based load balancing. The priority based server pool can be an alternative for the backup virtual servers. The ns.conf file requires minimal configuration compared to the backup virtual servers.

In priority based load balancing using SRV records, a priority number is assigned to each of the server pool. The least number has the highest priority. One of the servers in the highest priority pool is selected for load balancing based on the server's health and availability. If all the servers in the highest priority server pool are down, then the servers that have the next highest priority are selected for load balancing. However, if the servers in the highest priority server pool are up again, then the servers are selected from the highest priority pool again.

Switching from one priority server pool to another server pool occurs graciously by bleeding the existing client transactions. Therefore, the current clients do not see any break in the application access.

To enable querying for SRV records using the CLI

Perform the following tasks to enable querying for SRV records:

1. Create a server by specifying the query type parameter as SRV.

   At the command prompt, type:

   ```
   add server <name> <domain> [-queryType <queryType>])
   ```

   Example:

   ```
   add server web_serv example.com -queryType SRV
   ```

   Note:

   - By default, IPv4 queries are sent. To send IPv6 queries, you must enable the IPv6 domain.
   - The SRV target domain name must not exceed 127 characters.

2. Create a service group with the autoscale mode as DNS.

   At the command prompt, type:

   ```
   add serviceGroup <serviceGroupName> <serviceType> [-autoScale <
       autoScale>]
   ```

   Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add servicegroup svc_grp_1 http -autoscale dns
```

3. Bind the server created in step 1 to the service group as a member.

   At the command prompt, type:

   ```
   bind serviceGroup <serviceGroupName> <serverName>
   ```

   Example:

   ```
   bind servicegroup svc_grp_1 web_serv
   ```

> **Note:**
>
> - When binding servers to service group members, you do not have to enter the port number for SRV server types. In case you specify a port number for SRV server type, an error message appears.
> - You can optionally specify a name server and a TTL value while binding a server to the service group.

To enable querying for SRV records using the GUI

Create a server

1. Navigate to **Traffic Management** > **Load Balancing** > **Servers** and click **Add**.
2. In **Create Server** page, select domain name.
3. Enter the details of all the required parameters.
4. In **Query Type**, select **SRV**.
5. Click **Create**.

Create a service group with autoscale mode as DNS

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Load Balancing Service Group** page, enter details of all the required parameters.
3. In **AutoScale Mode**, select **DNS**.
4. Click **OK**.

Bind server to the service group member

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Close**.

> **Note:**
>
> - While binding, you do not have to enter the port number for SRV server types. In case you enter a port number for SRV server type, an error message appears.
> - You can optionally specify a name server and a TTL value while binding a server to the service group.

Overwriting TTL values

Citrix ADC appliance is configured to periodically query the DNS server for any update in the SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding the service group member and also globally, then the TTL value specified while binding the service group member takes precedence.
If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```
bind serviceGroup <serviceGroupName> (<serverName> [-dbsTTL <secs
   >])
```

Example:

```
bind servicegroup svc_grp_1 web_serv -dbsTTL 10
```

- To overwrite the TTL value globally, at the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set lb parameter [-dbsTTL <secs>]
```

Example:

```
set lb parameter -dbsTTL 15
```

Overwriting the TTL values using the GUI

To overwrite the TTL value while binding:

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Domain Based Service TTL**, enter the TTL value.

To overwrite the TTL value at the global level:

1. Navigate to **Traffic Management** > **Load Balancing** > **Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

> **Note**: If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

Specifying different name servers for service group and domain name bindings

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a nameserver is not specified while binding a member to the service group, the globally configured nameserver is considered.

Specifying name servers while binding a server to service groups using the CLI

At the command prompt, type:

```
bind serviceGroup <serviceGroupName> (<serverName> [-nameServer <
    ip_addr>] [-dbsTTL <secs>])
```

Example:

```
bind servicegroup svc_grp_1 web_serv  -ns.nameserver.com 10.102.27.155
    -dbsTTL 10
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Specifying name servers while binding a server to service groups using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for the bound domain must be sent.

Translate the IP address of a domain-based server

September 14, 2021

To simplify maintenance on the Citrix ADC appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address when you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks particular octets in the original server's IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address. The reference to the original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

To configure a translation IP address for a server by using the command line interface

At the command prompt, type:

```
add server <name>@ <serverDomainName> -translationIp <
   translationIPAddress> -translationMask <netMask> -state <ENABLED|
   DISABLED>
```

Example:

```
add server myMaskedServer www.example.com -translationIp 10.10.10.10 -
   translationMask
255.255.0.0 -state ENABLED
```

To configure a translation IP address for a server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Servers**, create a domain-based server, and specify a translation IP address.

Mask a virtual server IP address

September 17, 2021

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works differently from the IP pattern definition for a server described in Translating the IP Address of a Domain-Based Server. For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Also, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

Note: The Citrix ADC appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers.

When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
- Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it is sent to Virtual Server 2.

Note: Ports are also considered if a tie-breaker is required.

To configure a virtual server IP address mask by using the command line interface

At the command prompt, type:

```
add lb vserver <name>@ http -ipPattern <ipAddressPattern> -ipMask <
    ipMask> <listenPort>
```

Example:

Pattern matching based on prefix octets:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add lb vserver myLBVserver http -ippattern 10.102.0.0 -ipmask
    255.255.0.0 80
```

Pattern matching based on trailing octets:

```
add lb vserver myLBVserver1 http -ippattern 0.0.22.74 -ipmask
    0.0.255.255 80
```

Modify a pattern-based virtual server:

```
set lb vserver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255
```

If you configure the Virtual Server 1 as follows:

```
add lb vserver vs1 HTTP -ippattern 100.1.1.0 -ipmask 255.255.255.0 80
```

The Citrix ADC appliance will not respond to an ARP request on all the IP addresses. However, it responds to the virtual server traffic routed to all the IP addresses in that pattern.

To configure a virtual server IP address mask by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the Address Type list, select IP Pattern, and specify an IP pattern and IP mask.

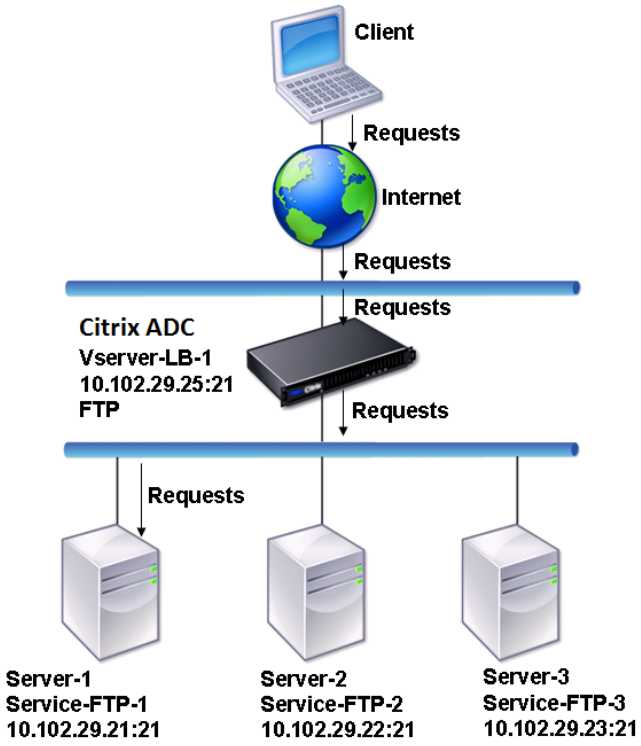
Configure load balancing for commonly used protocols

September 14, 2021

In addition to websites and web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your Citrix ADC appliance to use domain names for your servers rather than IPs, you might also need to set up IP translation and masking for those servers.

Load balance a group of FTP servers



August 16, 2023

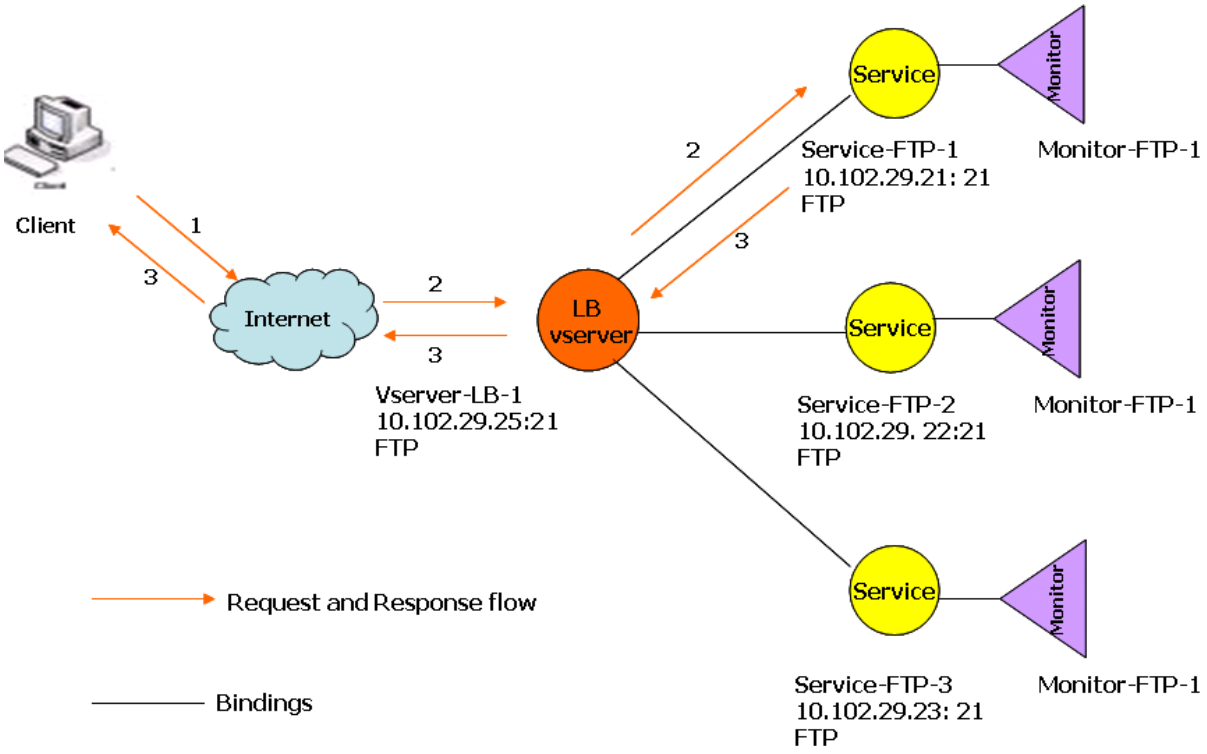
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The Citrix ADC appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

Figure 1. Basic Load Balancing Topology for FTP Servers

In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client's connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.



The following table lists the names and values of the basic entities configured on the appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity type	Name	IP address	Port	Protocol
Vserver	Vserver-LB-1	10.102.29.25	21	FTP
Services	Service-FTP-1	10.102.29.21	21	FTP
	Service-FTP-2	10.102.29.22	21	FTP
	Service-FTP-3	10.102.29.23	21	FTP
Monitors	FTP	None	None	None

The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing FTP Servers Entity Model

The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see Setting Up Basic Load Balancing. Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Next, bind the FTP monitor to the services by following the procedure described in the section Binding Monitors to Services.

To create FTP monitors by using the CLI

At the command prompt, type:

```
add lb monitor <MonitorName> FTP -interval <Interval> -userName <
   UserName> -password <Password>
```

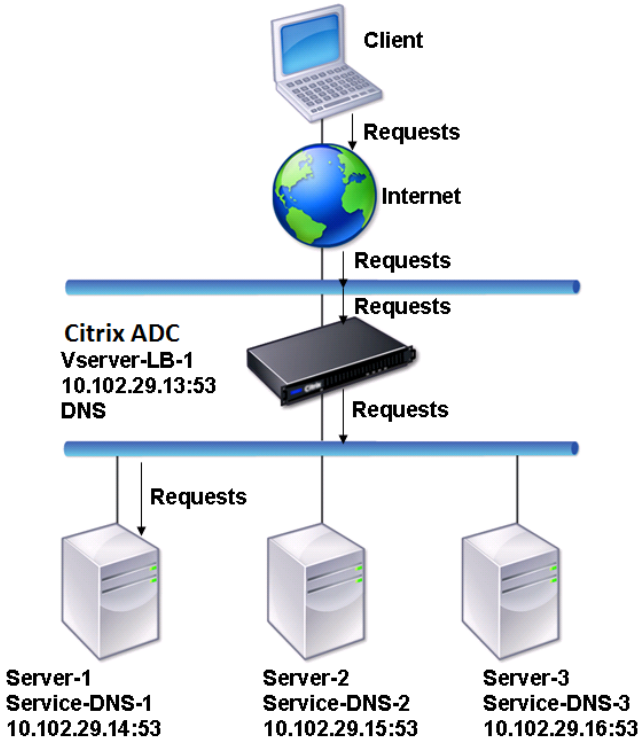
Example:

```
add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password
    User
```

To create FTP monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor of type FTP, and in Special Parameters, specify a user name and password.

Load balance DNS servers



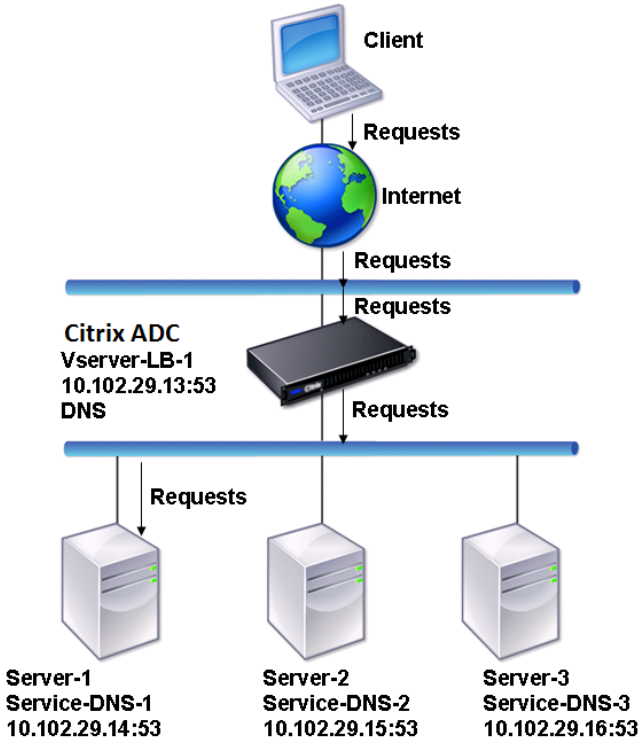
August 16, 2023

When you request DNS resolution of a domain name, the Citrix ADC appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improve DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

Figure 1. Basic Load Balancing Topology for DNS Servers

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.13	53	DNS
Services	Service-DNS-1	10.102.29.14	53	DNS
	Service-DNS-2	10.102.29.15	53	DNS
	Service-DNS-3	10.102.29.16	53	DNS
Monitors	monitor-DNS-1	None	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DNS Servers Entity Model

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure a basic DNS load balancing setup, see Setting Up Basic Load Balancing. Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the parameters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see Binding Monitors to Services.
The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

To configure DNS monitors by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> DNS -query <domainName> -queryType <
    Address|ZONE> -IPAddress <ipAddress>
```

Example:

```
add lb monitor monitor-DNS-1 DNS -query www.citrix.com -queryType
    Address -IPAddress 10.102.29.66

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
3 add lb monitor monitor-DNS-2 DNS -query www.citrix2.com -queryType
     Address -IPAddress
4 1000:0000:0000:0000:0005:0600:700a::888b-888d
```

To configure DNS monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor of type DNS, and in Special Parameters, specify a query and query type.

Load balance domain-name based services

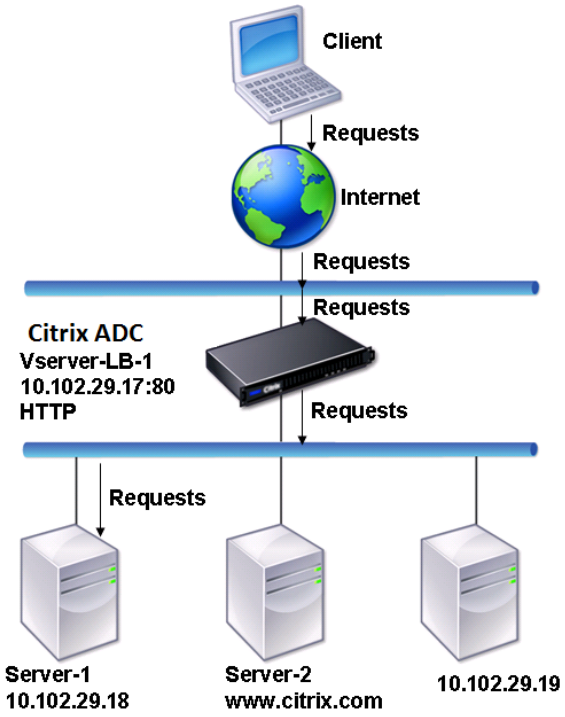
August 16, 2023

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4 or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the Citrix ADC configuration.

When you configure services with domain names instead of IP addresses, and if the name server resolves the domain name to a new IP address, the monitor bound to the service runs a health check on the new IP address, and updates the service IP address only when the IP address is found to be healthy. The monitor can be the default monitor bound to the service or you can bind any other supported monitor. It probes the service at regular intervals defined in the monitor parameters. If the domain name resolves to a new IP address, the monitor sends a fresh probe to check the health of the service. All subsequent probes are at the predefined interval.

Note: When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

Domain-name based services have the following restrictions:



- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.
- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

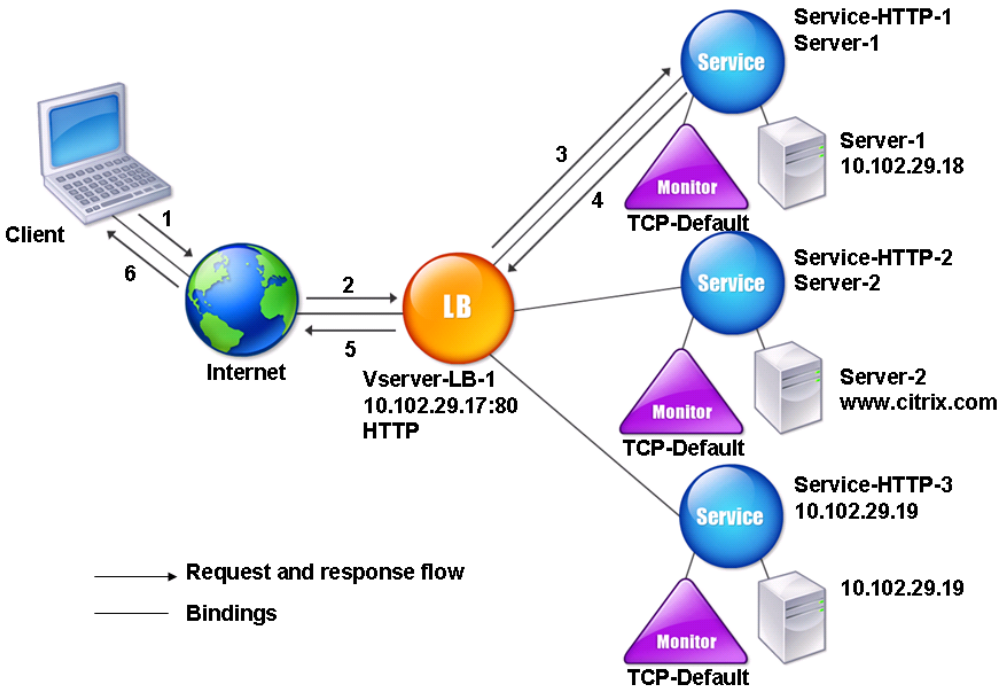
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of "name error"(3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances the load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).

Figure 1. Basic Load Balancing Topology for DBS Servers

The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.



Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.17	80	HTTP

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity type	Name	IP address	Port	Protocol
	Vserver-LB-2	10.102.29.20	53	DNS
Servers	server-1	10.102.29.18	80	HTTP
	server-2	www.citrix.com	80	HTTP
Services	Service-HTTP-1	server-1	80	HTTP
	Service-HTTP-2	server-2	80	HTTP
	Service-HTTP-2	10.102.29.19	80	HTTP
Monitors	Default	None	None	None
Name Server	None	10.102.29.19	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DBS Servers Entity Model

To configure a basic load balancing setup, see Setting Up Basic Load Balancing. Create the services

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

To add a name server by using the command line interface

At the command prompt, type:

```
add dns nameServer <dnsVserverName>
```

Example:

```
add dns nameServer Vserver-LB-2
```

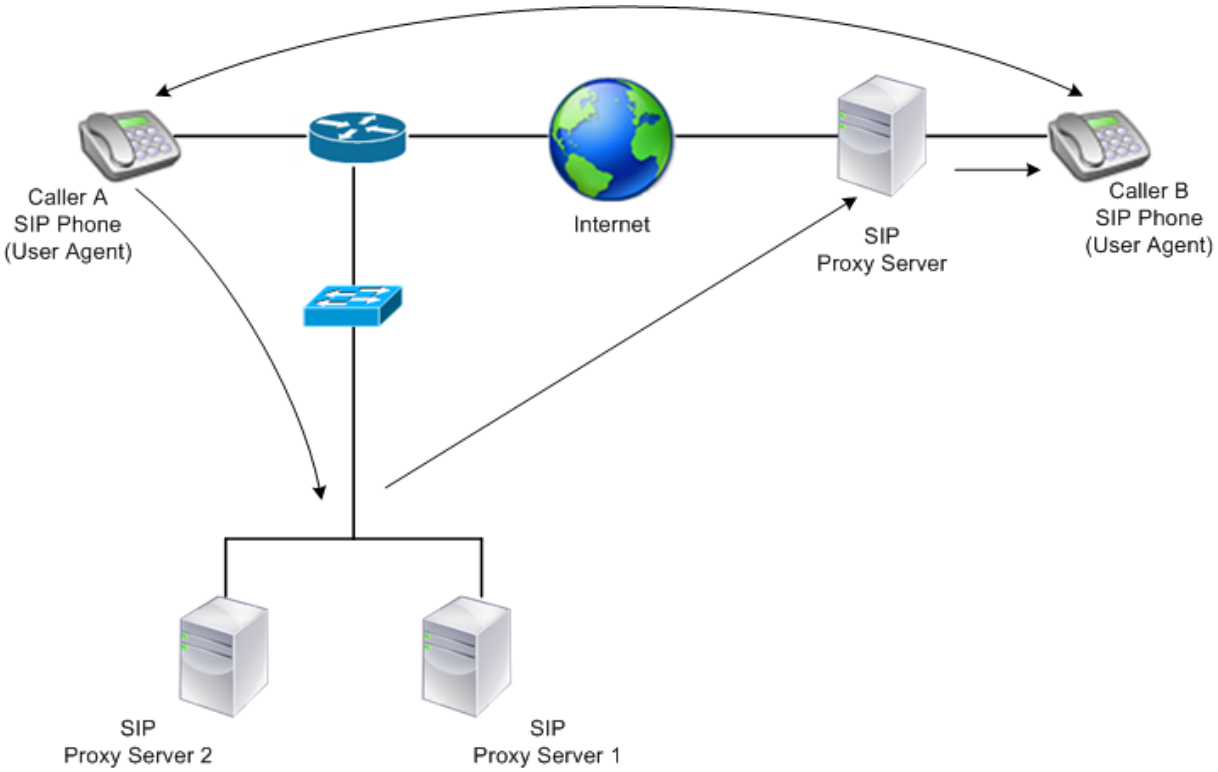
To add a name server by using the configuration utility

1. Navigate to **Traffic Management** > **DNS** > **Name Servers**.
2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.

You can also add an authoritative name server that resolves the domain name to an IP address.

> **Note**
>
> You can add a name server of type TCP, UDP, or UDP_TCP to resolver DBS probes. However, if TCP and UDP name servers coexists, and a UDP name server receives a response with the truncated bit, this response is not retried over the TCP name server.

Load balance a group of SIP servers



September 14, 2021

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Figure 1. SIP Based Communication System

A Citrix ADC enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the Citrix ADC to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the Citrix ADC appends RPORT via the header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.

Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

Server Initiated Traffic

For SIP-server initiated outbound traffic, configure RNAT on the Citrix ADC so that the private IP addresses used by the clients are translated into public IP addresses.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

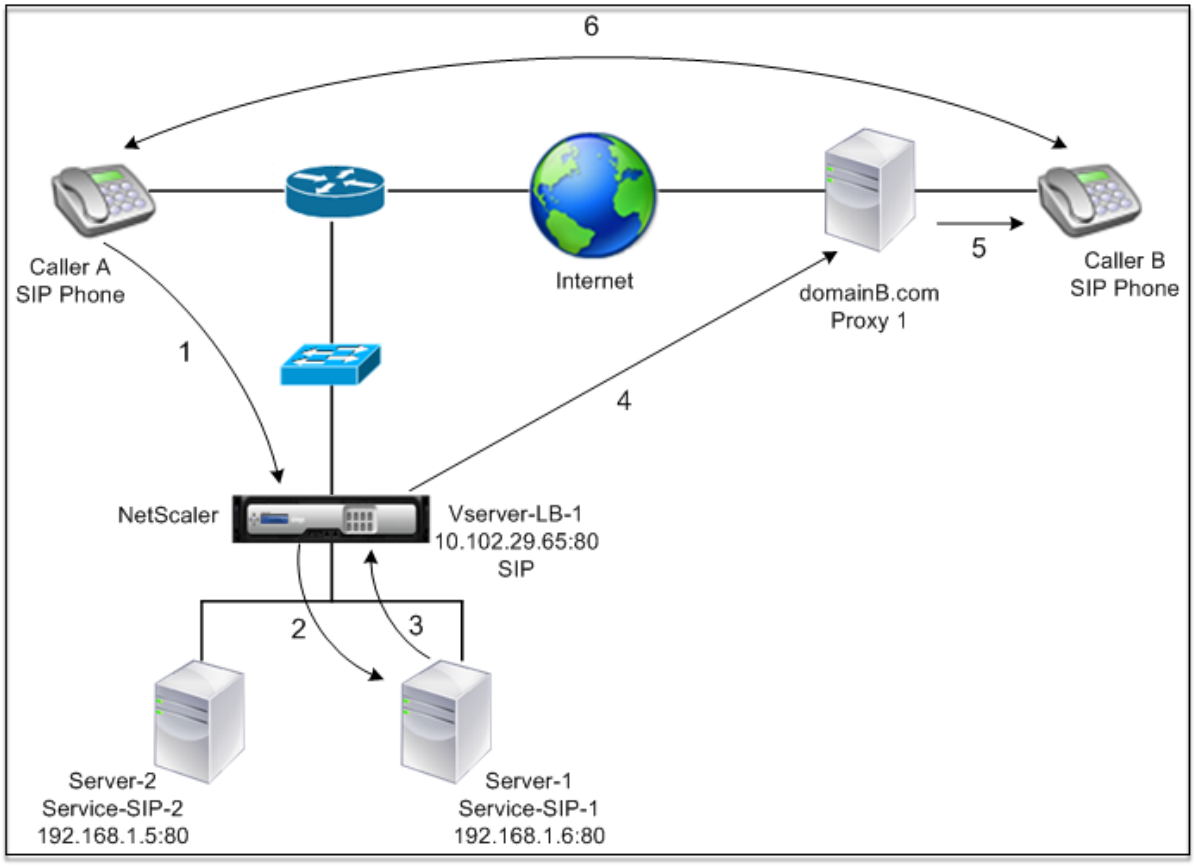
If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the Citrix ADC uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named **nsrnatsip-127.0.0.1-5061**.

Support for Policies and Expressions

The Citrix ADC default expressions language contains several expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (sip_udp, sip_tcp or sip_ssl) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.

Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP



The Citrix ADC can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- SIP_UDP –Used when SIP servers send SIP messages over UDP.
- SIP_TCP –Used when SIP servers send SIP messages over TCP.
- SIP_SSL –Used to secure SIP signaling traffic over TCP by using SSL or TLS. The Citrix ADC supports the following modes:
  - End-to-end TLS connection between the client, the ADC, and the SIP server.
  - TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
  - TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.

Figure 2. SIP Load Balancing Topology

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity type	Name	IP address	Port	Service type / Protocol
Virtual Server	Vserver-LB-1	10.102.29.65	80	SIP_UDP / SIP_TCP / SIP_SSL
Services	Service-SIP-1	192.168.1.6	80	SIP_UDP / SIP_TCP / SIP_SSL
	Service-SIP-2	192.168.1.5	80	SIP_UDP / SIP_TCP / SIP_SSL
Monitors	Default	None	80	SIP_UDP / SIP_TCP / SIP_SSL

Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **SIP_UDP** –If you are load balancing the SIP traffic over UDP.
- **SIP_TCP** –If you are load balancing the SIP traffic over TCP.
- **SIP_SSL** –If you are load balancing and securing the SIP traffic over TCP.

Note: If you use SIP_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.

2. Bind the services to the virtual servers.
3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The Citrix ADC provides two custom monitor types, **SIP-UDP** and **SIP-TCP**, for monitoring SIP services.
4. If using a SIP_SSL virtual server, bind an SSL certificate-key pair to the virtual server.
5. If you are using the Citrix ADC as the gateway for the SIP servers in your deployment, configure RNAT.
6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.

To configure a basic load balancing setup for SIP traffic by using the command line interface

Create one or more services. At the command prompt, type:

```
add service <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
```

Example:

```
add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80
```

Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you bind to it. At the command prompt, type:

```
add lb vserver <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
```

Example:

```
add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80
```

Bind each service to a virtual server. At the command prompt, type:

```
bind lb vserver <name> <serverName>
```

Example:

```
bind lb vserver Vserver-LB-1 Service-SIP-UDP-1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

(Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> [<interval>]

bind lb monitor <monitorName> <ServiceName>
```

Example:

```
add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipuRI sip:mon@test.
   com -sipregURI sip:mon@test.com -respcode 200

bind monitor mon1 Service-SIP-UDP-1
```

If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:

```
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -
   CA – skipCAName
```

Example:

```
bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
```

Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

```
add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))

bind rnat <name> <natIP>@ ...

show rnat
```

Example:

```
add rnat RNAT-1 192.168.1.0 255.255.255.0

bind rnat RNAT-1 -natip 10.102.29.50
```

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named nsrnatsip-127.0.0.1-5061.

```
add ssl certKey <certkeyName> -cert <string> [-key <string>]

bind ssl service <serviceName> -certkeyName <string>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
add ssl certKey c1 -cert cert.epm -key key.ky

bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1
```

If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt:

```
set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort<
    rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> -
    sip503RateThreshold <sip503_rate_threshold_value>
```

Sample Configuration for load balancing the SIP traffic over UDP

    -addRportVip ENABLED -sip503RateThreshold 1000

Done
```

To configure a basic load balancing setup for SIP traffic by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and add a virtual server of type SIP_UDP, SIP_TCP, or SIP_SSL.
2. Click the **Service** section, and add a service of type SIP_UDP, SIP_TCP, or SIP_SSL.
3. (Optional) Click the **Monitor** section, and add a monitor of the type: SIP-UDP or SIP-TCP.
4. Bind the monitor to the service, and bind the service to the virtual server.
5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.
6. Configure RNAT as required by your network topology. To configure RNAT:
   a) Navigate to **System > Network > Routes**.
   b) On the Routes page, click the **RNAT** tab.
   c) In the details pane, click **Configure RNAT**.
   d) In the Configure RNAT dialog box, do one of the following:
      - If you want to use the network address as a condition for creating an RNAT entry, click **Network** and set the following parameters:
        - Network
        - Netmask
      - If you want to use an extended ACL as a condition for creating an RNAT entry, click **ACL** and set the following parameters:
        - ACL Name
        - Redirect Port
   e) To set a SNIP address as a NAT IP address, skip to step 7.
   f) To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IPs' list.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

g) Click Create, and then click Close.

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named **nsrnatsip-127.0.0.1-5061**. To bind the pair:

a) Navigate to **Traffic Management > Load Balancing > Services** and click the Internal Services tab.
b) Select nsrnatsip-127.0.0.1-5061 and click **Edit**.
c) Click the **Certificates** section and bind a certificate key pair to the internal service.

7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP parameters. Navigate to **Traffic Management > Load Balancing** and click Change SIP settings, set the various SIP parameters.

SIP Expression and Policy Example: Compression Enabled in Client Requests

A Citrix ADC cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and looks for the compression header. If the message includes a compression header, the policy responds with "400 Bad Request,"so that the client resends the request without compressing it.

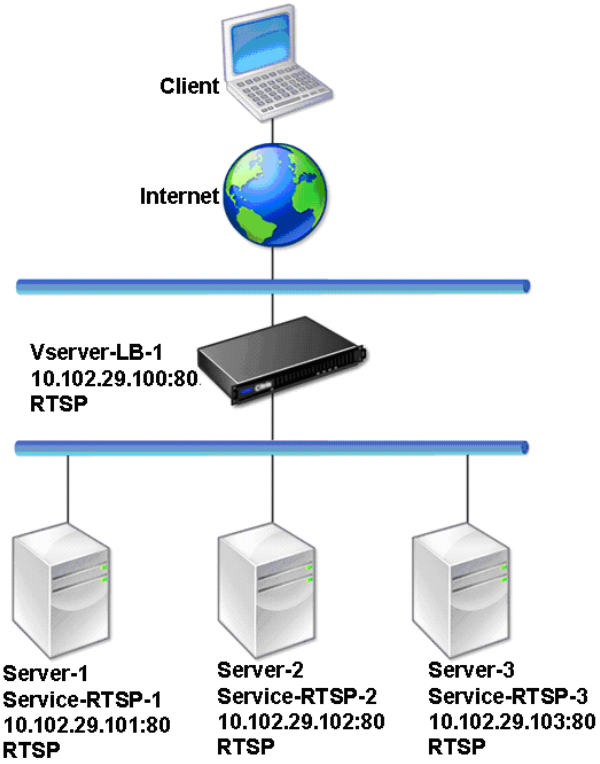
At the command prompt, type the following commands to create the responder policy:

```
add responder action sipaction1 respondwith q{
 "SIP/2.0 400 Bad Requestrnrn" }

Done

add responder policy sippol1

add responder policy sippol1 "SIP.REQ.METHOD.EQ("NEGOTIATE")&&SIP.REQ.
   HEADER("Compression").EXISTS" sipaction1
```



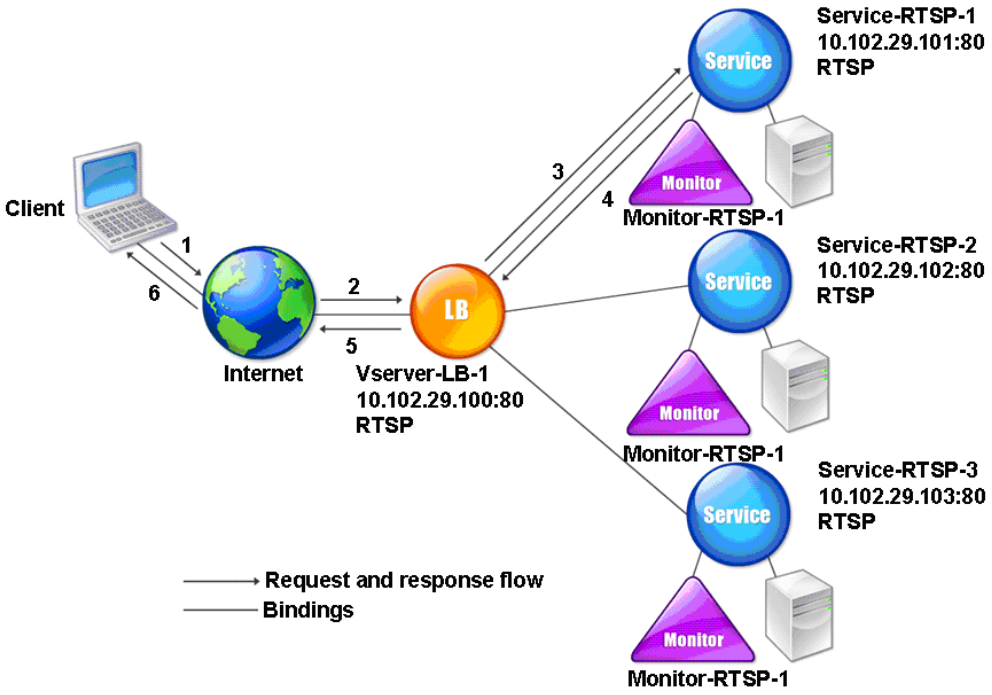
Load balance RTSP servers

September 14, 2021

The Citrix ADC appliance can balance the load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of a load balancing setup configured to load balance a group of RTSP servers.

Figure 1. Load Balancing Topology for RTSP

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.100	554	RTSP
Services	Service-RTSP-1	10.102.29.101	554	RTSP
	Service-RTSP-2	10.102.29.102	554	RTSP
	Service-RTSP-3	10.102.29.103	554	RTSP
Monitors	Monitor-RTSP-1	None	554	RTSP

The following diagram shows the load balancing entities used in the RTSP configuration.

Figure 2. Load Balancing RTSP Servers Entity Model

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure a basic load balancing setup for RTSP servers, see Setting Up Basic Load Balancing. Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see Binding Monitors to Services. The following procedure describes how create a monitor that checks RTSP servers.

To configure RTSP monitors by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <type>
```

Example:

```
add lb monitor Monitor-RTSP-1 RTSP
```

To configure RTSP monitors by using the GUI

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type RTSP.

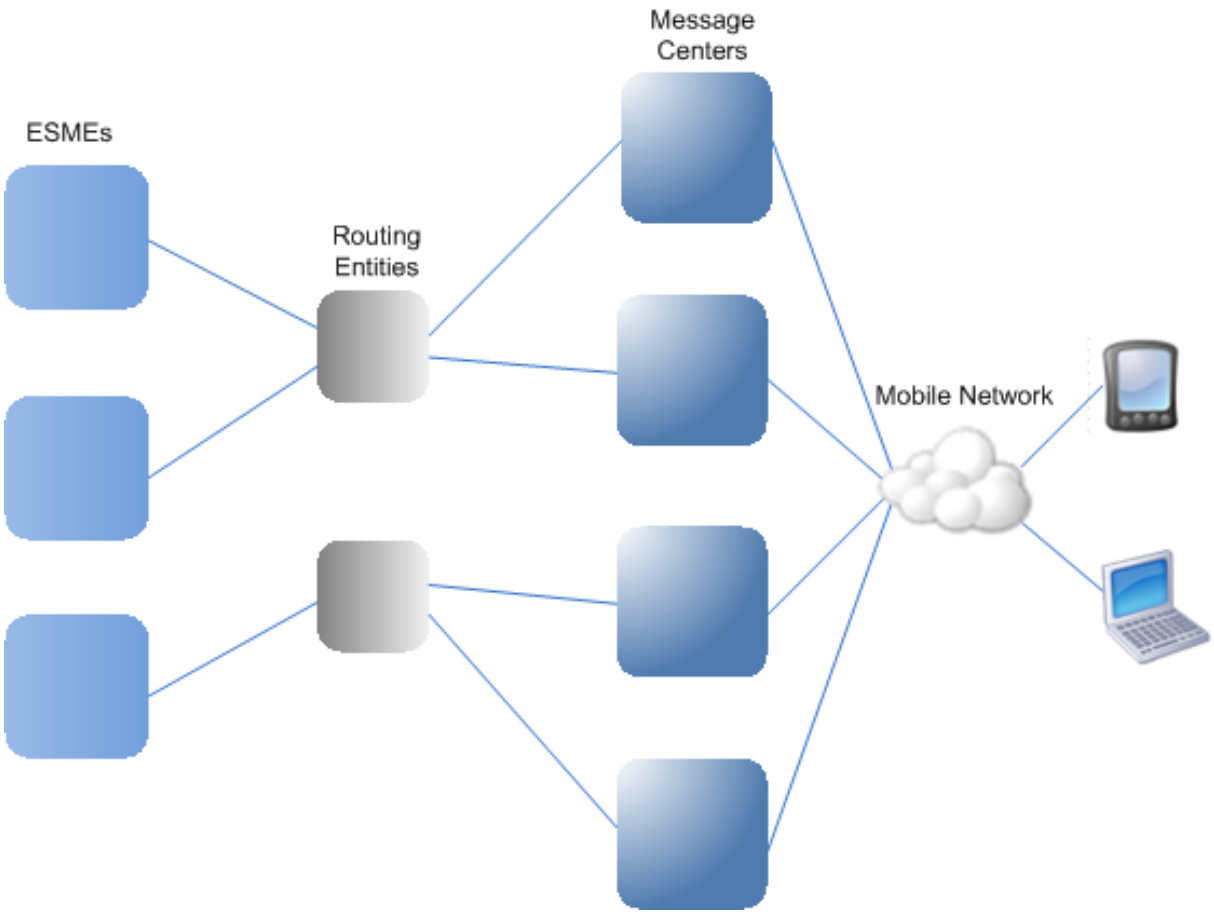
Use case 1: SMPP load balancing

September 14, 2021

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers. The Citrix ADC supports SMPP load balancing and provides optimal distribution of messages across your servers, preventing poor performance and outages.

The Citrix ADC performs load balancing on the server side when messages are received from clients and on the client side when messages are received from servers.

Load balancing of SMPP messages by the Citrix ADC provides the following benefits:



- Better load distribution on servers, which translates to faster response time to end users
- Server health monitoring and better failover capabilities
- Quick and easy addition of new servers (message centers) without changing the client configuration
- High availability

Introduction to SMPP

SMPP is an application layer protocol for the transfer of short messages between External Short Message Entities (ESME), Routing Entities (RE) and Message Centers (MC) over long-lived TCP connections. It is used for sending short message service (SMS) messages between friends, contacts, and third parties such as banks (mobile banking), advertisers (mobile commerce), and directory services. Messages from an ESME (non-mobile entity) arrive at the MC, which distributes them to short message entities (SMEs) such as mobile phones. SMPP is also used by SMEs to send short messages to third parties (for example, for purchase of products, bill payment, and funds transfer). These messages arrive at the MC and are forwarded to the destination MC or ESME.

The following diagram shows the different SMPP entities: ESMEs, REs, and MCs, in a mobile network.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

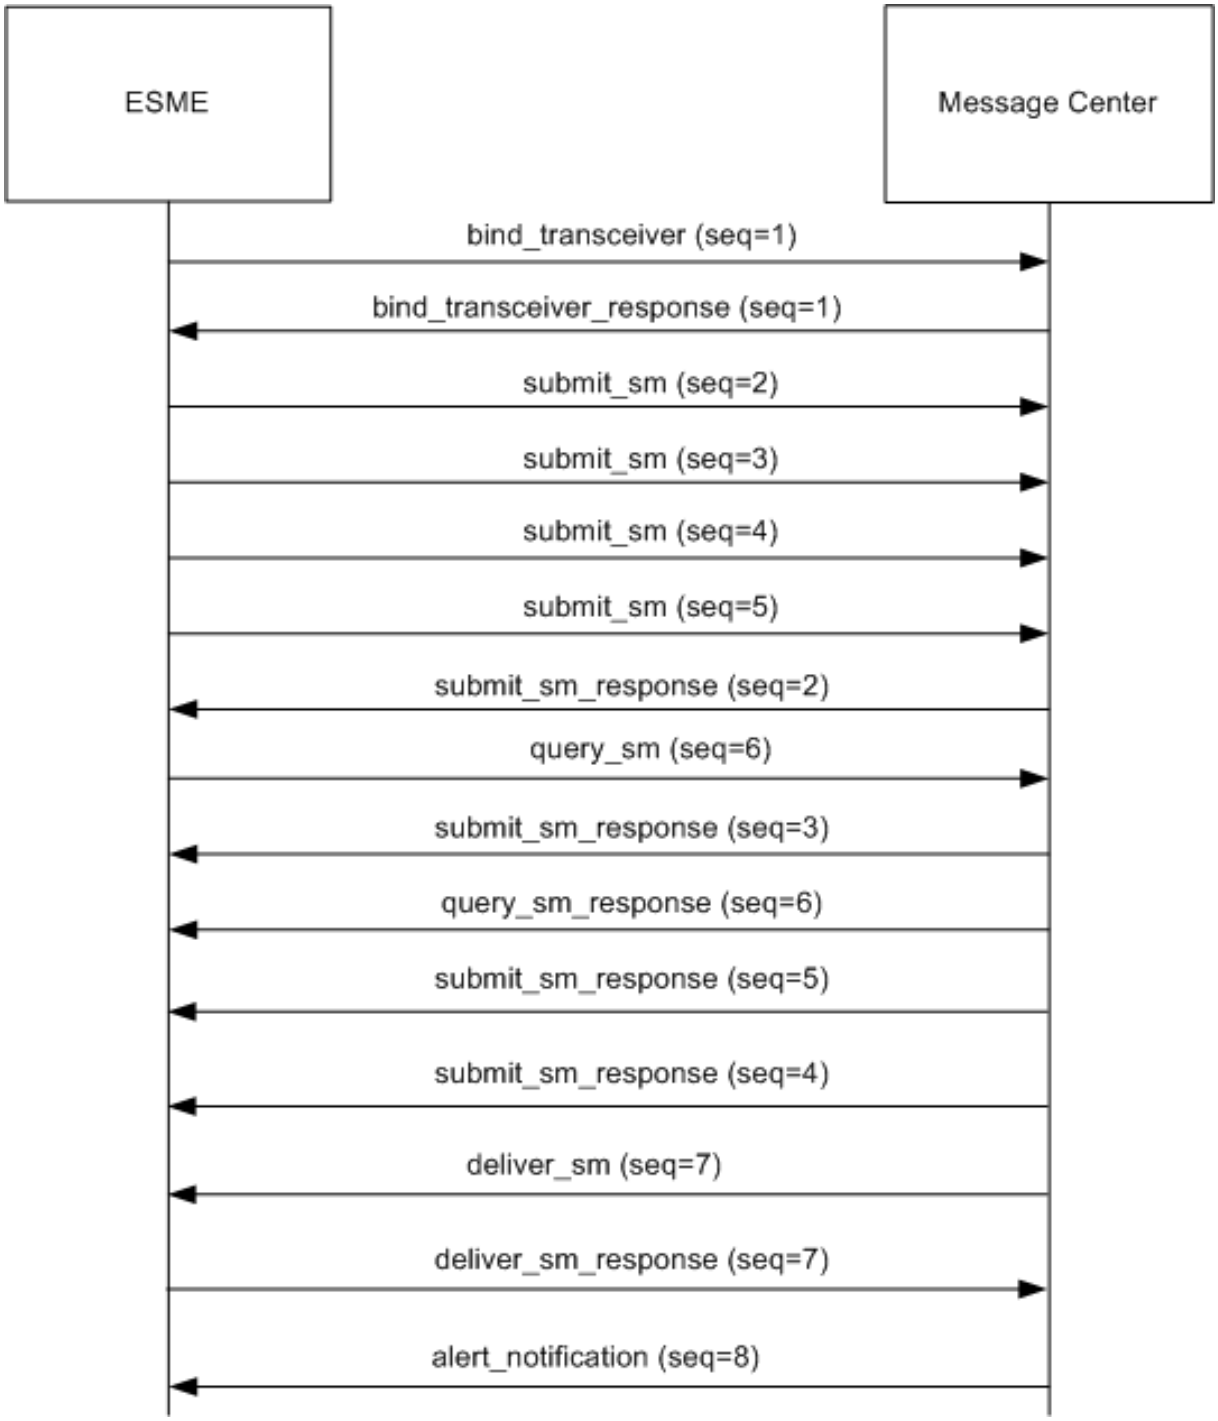
Architecture Overview of the Different SMPP Entities in a Mobile Network

Note: The terms client and ESME are used interchangeably throughout the document.

An ESME (client) opens a connection to the MC in one of the three modes: as a transmitter, a receiver, or a transceiver. As a transmitter, it can only submit messages for delivery. As a receiver, it can only receive messages. As a transceiver, the ESME can both submit and receives messages. The ESME sends the MC one of the three messages (also known as PDUs): bind_transmitter, bind_receiver, or bind_transceiver. The MC responds with a bind_transmitter_resp, bind_receiver_resp, or bind_transceiver_resp, as appropriate for the request.

After the connection is established, the ESME can, depending on the mode in which it is bound to the MC, send a submit_sm or data_sm message, receive a deliver_sm or data_sm message, or send and receive any of these types of messages. The ESME can also send ancillary messages, such as query_sm, replace_sm, and cancel_sm, to query the status of an earlier message delivery, replace an earlier message with a new message, or cancel an undelivered message.

If a message is not delivered because an ESME is not available or a mobile subscriber is not online, the message is queued. Later, when the MC detects that the mobile subscriber is now reachable, it sends



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

an alert_notification PDU to the ESME over a receiver or transceiver session, requesting delivery of any queued messages.

Each request PDU has a unique sequence number. The response PDU has the same sequence number as the original request. Because message exchange over SMPP can be in asynchronous mode, an ESME or an MC can send multiple requests at a time. The sequence number plays a crucial role in returning the response in the same SMPP session. In other words, the sequence number makes request and response matching possible.

The following diagram shows how the traffic flow uses the various PDUs when the ESME binds as a transceiver.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Limitation:

The Citrix ADC appliance does not support out bound operations. That is, a message center cannot initiate an SMPP session with an ESME through the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

How SMPP Load Balancing Works on the Citrix ADC

An ESME (client) sends a bind message to open a connection to the Citrix ADC. The ADC authenticates each ESME and, if successful, responds with an appropriate message. The Citrix ADC establishes a connection with each message center and load balances all the messages among these message centers. When the ADC receives a message from a client, it reuses an open connection to the message center or sends a bind request to a message center if an open connection is not available.

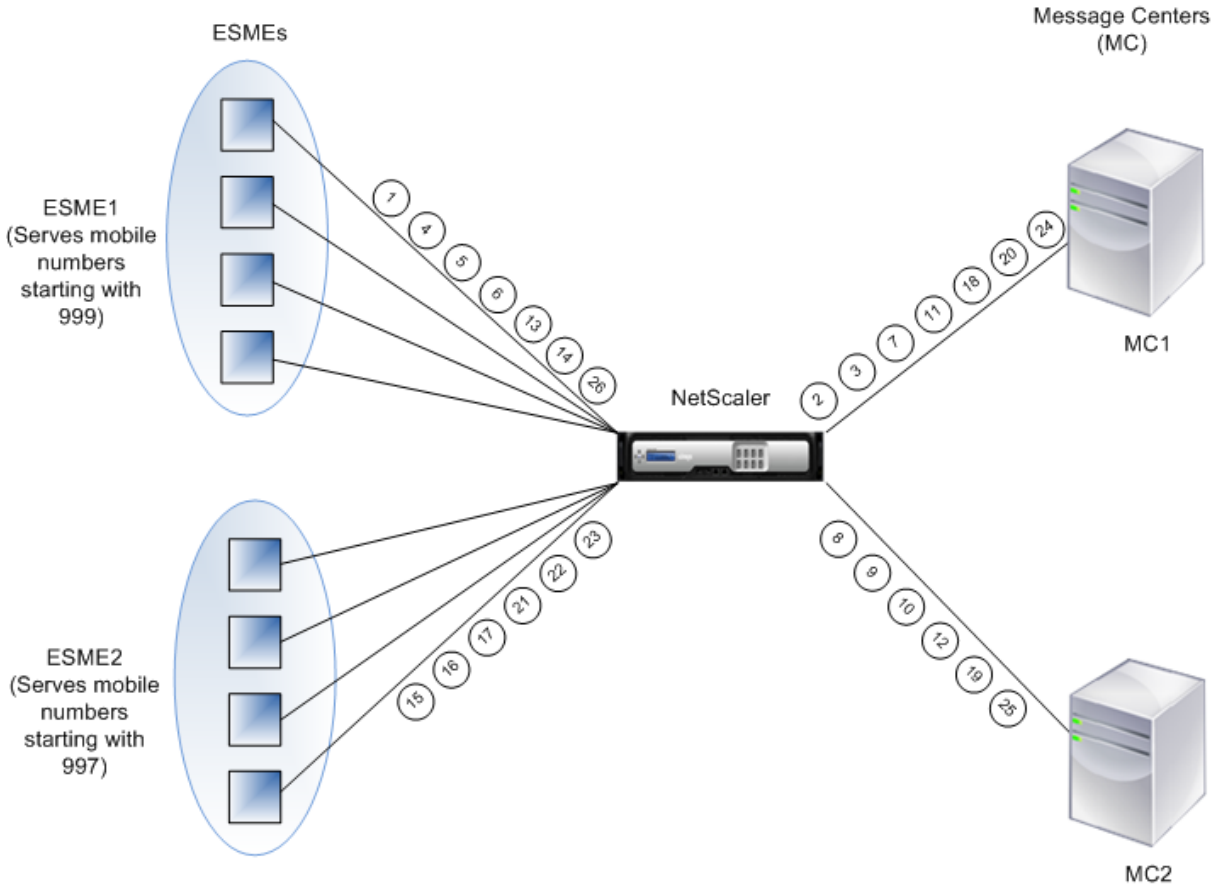
The ADC can load balance messages originating from the clients and from the servers. It can monitor the health of the message centers and handle concatenated messages. It also provides content switching support for the message centers.

Messages Originating from the ESMEs

Each ESME must be added as a user on the Citrix ADC for authentication. The client establishes a TCP connection with an SMPP virtual server configured on the ADC by sending a bind request. The ADC authenticates the client and, if successful, parses the bind message. The ADC then sends the request to the message center selected by the configured load balancing method. If a connection to the message center is not available for reuse, the ADC opens a TCP connection with the message center by sending a new bind request to the message center.

Before forwarding the response (submit_sm_resp or data_sm_resp) from the message center to the client, the ADC adds a custom server ID to the message ID to identify the message center for ancillary operations, such as query, replace, or cancel requests for a message, by the client. Requests from other clients are load balanced in the same way.

In the original bind request, a client specifies the address range that it can serve. This range is used for forwarding deliver_sm or data_sm messages from the message centers to the clients.



Messages Originating from a Message Center

ESMEs that can handle a specific address range are grouped into a cluster. All the nodes in a cluster provide the same credentials. Within a cluster, only the round robin method is used for load balancing. To deliver mobile originated (MO) messages, the message center sends a deliver_sm message to the Citrix ADC. If a cluster that can serve the destination address range (for example, numbers starting with 998) is bound to the ADC, it selects that cluster, and then load balances the message among the ESME nodes in that cluster.

If an ESME that can serve deliver_sm messages for the address range is not bound to the ADC, and message queuing is enabled, the message is queued until such a client binds to the ADC in a receiver or transceiver mode. You can specify the size of the queue.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following diagram illustrates the internal flow of PDUs between ESMEs, Citrix ADC, and the message centers. For simplicity, only two ESMEs and two message centers are shown.

Flow of messages (PDUs):

1. ESME1 sends bind request to NetScaler
2. NetScaler sends bind request to MC1
3. MC1 sends bind response to NetScaler
4. NetScaler sends bind response to ESME1
5. ESME1 sends submit_sm(1) to NetScaler
6. ESME1 sends submit_sm(2) to NetScaler
7. NetScaler forwards submit_sm(1) to MC1
8. NetScaler sends bind request to MC2
9. MC2 sends bind response to NetScaler
10. NetScaler forwards submit_sm(2) to MC2
11. MC1 sends submit_sm_resp(1) to NetScaler
12. MC2 sends submit_sm_resp(2) to NetScaler
13. NetScaler forwards submit_sm_resp(1) to ESME1
14. NetScaler forwards submit_sm_resp(2) to ESME1
15. ESME2 sends bind request to NetScaler

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

16. NetScaler sends bind response to ESME2
17. ESME2 sends submit_sm(3) to NetScaler
18. NetScaler forwards submit_sm(3) to MC1
19. MC2 sends deliver_sm to NetScaler (ESME2 serves the address range specified in the message)
20. MC1 sends submit_sm_resp(3) to NetScaler
21. NetScaler forwards submit_sm_resp(3) to ESME2
22. NetScaler forwards deliver_sm to ESME2
23. ESME2 sends deliver_sm_resp to NetScaler
24. MC1 sends alert_notification to NetScaler (ESME1 serves the address range specified in the message)
25. NetScaler forwards deliver_sm_resp to MC2
26. NetScaler forwards the alert_notification to ESME1

Health Monitoring of Message Centers

By default, a TCP_default monitor is bound to an SMPP service, but you can bind a custom monitor of type SMPP. The custom monitor opens a TCP connection to the message center and sends an enquire_link packet. Depending on the success or failure of the probe, the service is marked UP or DOWN.

Content Switching on Message Centers

Message centers can accept multiple connections (or bind requests) from ESMEs. You can configure the Citrix ADC to content switch these requests based on the SMPP bind parameters. Following are some common expressions for configuring methods to select a message center:

- Based on the address range: In the following sample expression, the ADC selects a specific message center if the address range starts at 988.

Example:

SMPP.BINDINFO.ADDRESS_RANGE.CONTAINS(“^988”)

- Based the ESME ID: In the following sample expression, the ADC selects a specific message center if the ESME ID equals ESME1.

Example:

SMPP.BINDINFO.SYSTEM_ID.EQ(“ESME1”)

- Based on the ESME type: In the following sample expression, the ADC selects a specific message center if the ESME type is VMS. VMS stands for voice mail system.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

SMPP.BINDINFO.SYSTEM_TYPE.EQ(“VMS”)

- Based on the type of number (TON) of the ESME: In the following sample expression, the ADC selects a specific message center if TON equals 1 (1 stands for an international number.)

Example:

SMPP.BINDINFO.ADDR_TON.EQ(1)

- Based on the number plan indicator (NPI) of the ESME: In the following sample expression, the ADC selects a specific message center if NPI equals 0 (0 stands for an unknown connection.)

Example:

SMPP.BINDINFO.ADDR_NPI.EQ(0)

- Based on the bind type: In the following sample expression, the ADC selects a specific message center if the bind type is TRANSCEIVER. (A transceiver can send and receive messages.)

Example:

SMPP.BINDINFO.TYPE.EQ(TRANSCEIVER)

Concatenated Message Handling

An SMS can hold a maximum of 140 bytes. Longer messages must be broken down into smaller parts. If the destination mobile is capable, the messages are combined and delivered as one long SMS. The Citrix ADC forwards the fragments of a message to the same message center. Each message contains a reference number, a sequence number, and the total number of fragments. The reference number is the same for each fragment of a long message. The sequence number specifies that position of the particular fragment in the complete message. After all the fragments are received, the ESME combines the fragments into one long message and delivers the message to the mobile subscriber.

If a client disconnects from an active connection, the connection to the message center is not closed. It is reused for requests from other clients.

Limitation

Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the Citrix ADC responds with an error message.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring SMPP Load Balancing on the Citrix ADC

Perform the following tasks to configure SMPP load balancing on the ADC:

1. Add an SMPP user. The ADC authenticates the user before it accepts a bind request from the user. The user is typically an ESME.
2. Add a load balancing virtual server, specifying the protocol as SMPP.
3. Add a service, specifying the protocol as SMPP, and a custom server ID that is unique for each server. Bind the service to the load balancing virtual server created earlier.
4. Optionally, create a service group and add services to the service group.
5. Optionally, add a monitor of type SMPP-ECV and bind it to the service. A TCP-default monitor is bound by default.
6. Set the SMPP parameters, such as client mode and message queue.

To configure SMPP load balancing by using the command line

At the command prompt, type:

```
add smpp user <username> -password <password>
add service <name> <IP> SMPP <port>  – customserverID <customserverID>
add lb vserver <name> <IP> SMPP <port>
bind lb vserver <name> <service name>
set smpp param
```

Example

```
add smpp user smppclient1 -password c03ebb540695b6110eb31172f32245a1 -
    encrypted -encryptmethod ENCMTHD_2
add smpp user smppclient2 -password c03ebb540695b6110eb31172f32245a1 -
    encrypted -encryptmethod ENCMTHD_2
add service smmpsvc 10.102.84.140 SMPP 2775 -gslb NONE -maxClient 0 -
    maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout
     180 -svrTimeout 360 -CustomServerID ab -CKA NO -TCPB NO -CMP NO
add service smmpsvc2 10.102.81.175 SMPP 2775 -gslb NONE -maxClient 0 -
    maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout
     180 -svrTimeout 360 -CustomServerID xy -CKA NO -TCPB NO -CMP NO
add lb vserver smppvs SMPP 10.102.239.179 2775 -persistenceType NONE -
    cltTimeout 180
bind lb vserver smppvs smmpsvc2
bind lb vserver smppvs smmpsvc
set smpp param -addrrange "d*"
```

To configure SMPP load balancing by using the configuration utility

1. Navigate to **System > User Administration > SMPP Users**, and add an SMPP user.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. Navigate to **Traffic Management > Load Balancing > Configure SMPP Parameters**, and set the parameters as required by your deployment.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and add a virtual server of type SMPP.
4. Click in the Service section, add a service of type SMPP, and specify a Server ID.

Use case 2: Configure rule based persistence based on a name-value pair in a TCP byte stream

September 14, 2021

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called "FIX fields"). The field format is <tag>=<value><delimiter>. This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. In the example;

- The tag 35 indicates the message type.
- The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. A value of A for the tag 35 indicates that the message is a logon message.
- The delimiter is the nonprinting "Start of Header"(SOH) ASCII character (0x01), which is the caret symbol (^).
- Each field is also assigned a name. The field with tag 35 is the msgType field.

Following is an example of a logon message.

8=FIX.4.1 9=61 35=A 49=INVMGR 56=BRKR 34=1 52=20000426-12:05:06 98=0 108=30 10=157

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another. This variation depends on the message type, the preceding fields, and the lengths of the preceding values. It also varies based on the implementation from one to another, depending on whether custom fields have been defined. Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application. You want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to RULE and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule "CLIENT.TCP.PAYLOAD
(300).TYPECAST_NVLIST_T('=','^').VALUE("\49\")"
```

Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.

If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the Citrix ADC appliance creates a persistence session based on this value.

The argument to the PAYLOAD() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET_TEXT_MODE(IGNORECASE) function if you want the appliance to ignore the case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET_TEXT_MODE(IGNORECASE) and HASH functions:

```
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T('=','^').SET_TEXT_MODE(
IGNORECASE).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace <tag> with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression CLIENT.TCP.PAYLOAD(300).BEFORE_STR("^").AFTER_STR("<tag>=").
- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).SUBSTR(80,20).TYPE '=','^').VALUE("<tag>").
- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).TYPECAST_NVLIST_T('=','^').VALUE("<tag>",2).
  Note: If the second argument that is passed to the
  VALUE() function is
  n, the appliance extracts the value of the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

(n+1)
th instance of the field because the count starts from zero (
0).

Following are more examples of rules that you can use to configure persistence. Only the payload-based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- CLIENT.TCP.PAYLOAD(100)
- CLIENT.TCP.PAYLOAD(100).HASH
- CLIENT.TCP.PAYLOAD(100).SUBSTR(5,10)
- CLIENT.TCP.SRCPORT
- CLIENT.TCP.DSTPORT
- CLIENT.IP.SRC
- CLIENT.IP.DST
- CLIENT.IP.SRC.GET4
- CLIENT.IP.DST.GET4
- CLIENT.ETHER.SRCMAC.GET6
- CLIENT.ETHER.DSTMAC.GET5
- CLIENT.VLAN.ID

Use case 3: Configure load balancing in direct server return mode

September 14, 2021

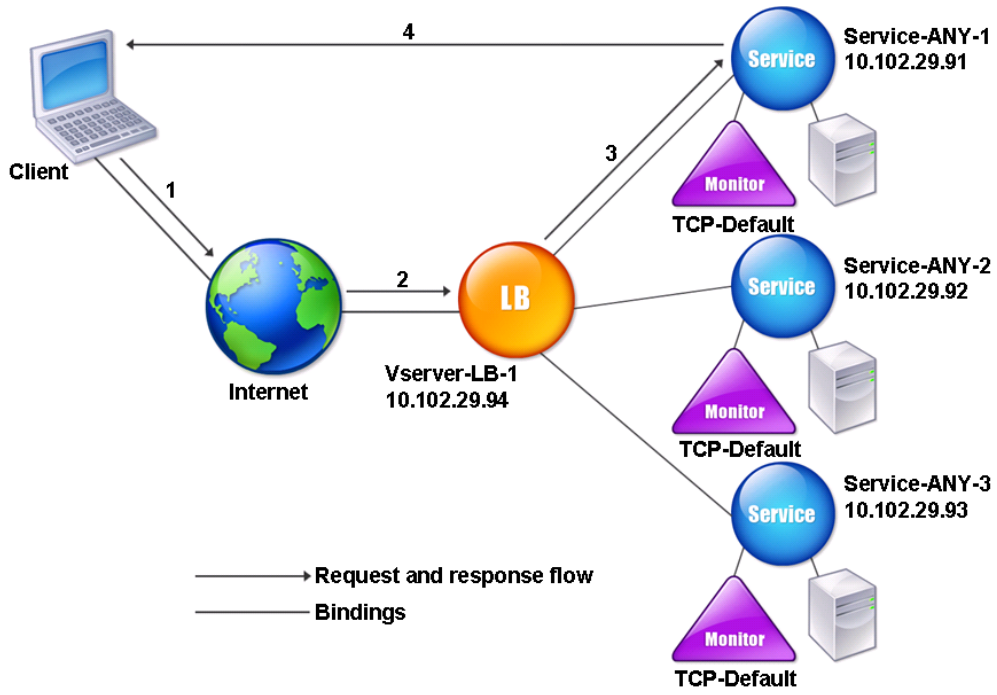
Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the Citrix ADC appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYNs to the server. To control the rate of SYNs, set a threshold for the rate of SYNs. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- In a DSR configuration, the Citrix ADC appliance does not replace the load balancing virtual server's IP address with the destination server's IP address. Instead, it forwards packets to a service by using the server's MAC address. The VIP must be configured on the server and ARP must be disabled for the VIP which is configured on the server. Doing so prevents the client request from bypassing the appliance when it is configured in one-arm mode. For example, a user must configure VIP in the loopback interface and disable the ARP for the same VIP.
- The appliance obtains the server's MAC address from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the Citrix ADC appliance, do not learn a server's MAC address. If you use only custom monitors in a DSR configuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the Citrix ADC appliance, the ARP requests always resolve to the MAC address of the Citrix ADC interface. Therefore, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.
- The Citrix ADC appliance learns the server L2 parameters from the monitor that is bound to the service. For UDP-ECV monitors, configure a receive string to enable the appliance to learn the L2 parameters of the server. If the receive string is not configured and the server does not respond, then the appliance does not learn the L2 parameters but the service is set to UP. The traffic for this service is blackholed.



In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the Citrix ADC appliance. The following table lists the names and values of the entities configured on the Citrix ADC appliance in DSR mode.

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY
	Service-ANY-3	10.102.29.93	ANY
Monitors	TCP	None	None

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server.

Next, you configure a basic load balancing setup as described in Setting Up Basic Load Balancing, naming the entities and setting the parameters using the values described in the previous table.

After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service. The service then uses the source IP address when forwarding responses.

To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <
    RedirectionMode> -sessionless <Value>
```

Example

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless
    enabled
```

> **Note**
>
> For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, select Redirection Mode as MAC Based, and method as SOURCEIPHASH.
3. In Traffic Settings, select Sessionless Load Balancing.

To configure a service to use source IP address by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
```

Example:

```
set service Service-ANY-1 -usip yes
```

To configure a service to use source IP address by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service, and in Traffic Settings, select **Use Source IP Address**.

Some additional steps are required in certain situations, which are described in the succeeding sections.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Use case 4: Configure LINUX servers in DSR mode

September 14, 2021

The LINUX operating system requires that you set up a loopback interface with the Citrix ADC appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

To configure LINUX server in DSR mode

To create a loop back interface with the Citrix ADC appliance's VIP on each load balanced server, at the Linux OS prompt type the following commands:

```
ifconfig dummy0 up

ifconfig dummy0:0 inet <netscaler vip> netmask 255.255.255.255 up

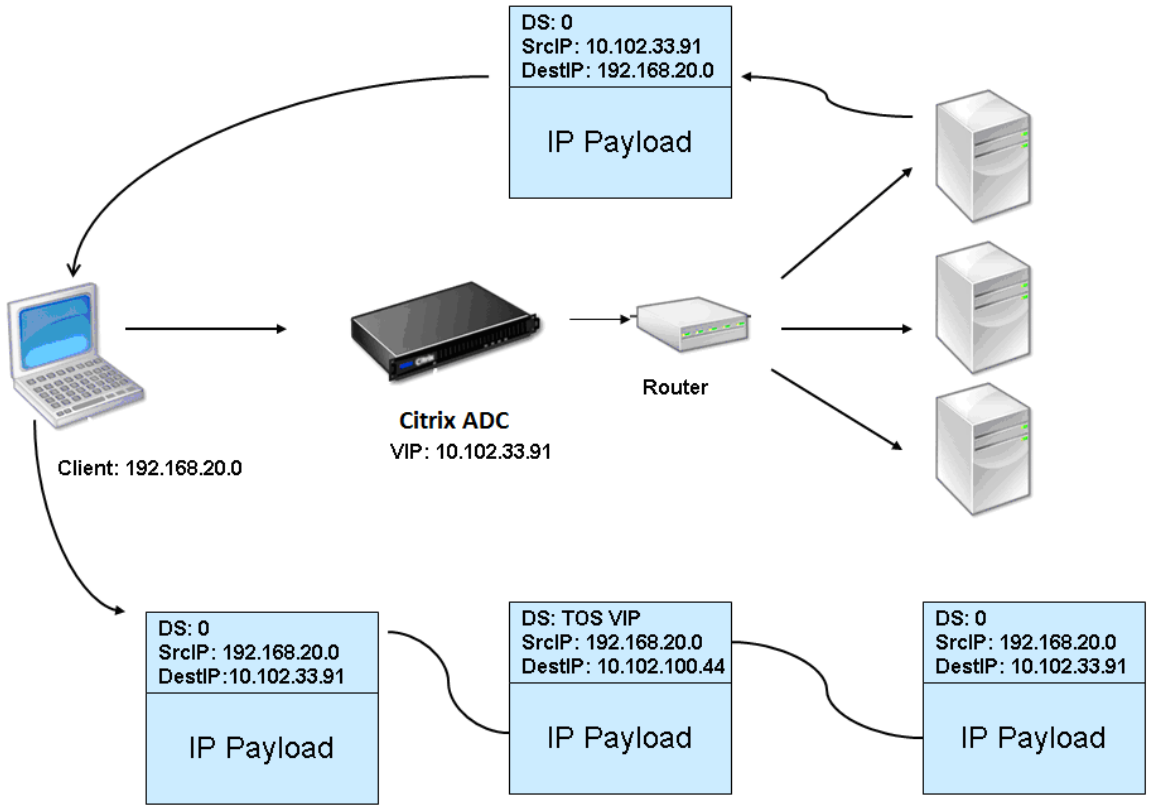
echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore

echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce
```

Then, run the software that remaps the TOS id to VIP.

Note: Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.

Use case 5: Configure DSR mode when using TOS



August 16, 2023

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the IPv4 packet header. The equivalent field in the IPv6 header is Traffic Class. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the Citrix ADC appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the **TOS** field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The Citrix ADC appliance in DSR mode with TOS

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The TOS feature is customized for a controlled environment as follows:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
- The intermediate router must not send out ICMP error messages regarding fragmentation. The client does not understand the message, as the source IP address is the IP address of the load balanced server and not the Citrix ADC VIP.
- TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity Type	Name	IP Address	Protocol
Virtual server	Vserver-LB-1	10.102.33.91	ANY
Services	Service-ANY-1	10.102.100.44	ANY
Monitors	PING	None	None

DSR with TOS requires that load balancing is set up on layer 3. To configure a basic load balancing setup for Layer 3, see Setting Up Basic Load Balancing. Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

To configure the redirection mode for the virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -m <Value> -tosId <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -m TOS -tosId 3
```

To configure the redirection mode for the virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and in Redirect Mode, select TOS ID.

To configure the transparent monitor for TOS by using the command line interface

At the command prompt, type:

```
add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -
    tosId <Value>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
add monitor mon1 PING -destip 10.102.33.91 -tos Yes  -tosId 3
```

To create the transparent monitor for TOS by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor, select TOS, and type the TOS ID that you specified for the virtual server.

Wildcard TOS Monitors

In a load balancing configuration in DSR mode using TOS field, monitoring its services requires a TOS monitor to be created and bound to these services. A separate TOS monitor is required for each load balancing configuration in DSR mode using the TOS field, because a TOS monitor requires the VIP address and the TOS ID to create an encoded value of the VIP address. The monitor creates probe packets in which the **TOS** field is set to the encoded value of the VIP address. It then sends the probe packets to the servers represented by the services of a load balancing configuration.

With many load balancing configurations, creating a separate custom TOS monitor for each configuration is a significant, cumbersome task. Managing these TOS monitors is also a significant task. Now, you can create wildcard TOS monitors. Create only one wildcard TOS monitor for all load balancing configurations that use the same protocol (for example, TCP or UDP).

A wildcard TOS monitor has the following mandatory settings:

- Type = <protocol>
- TOS = Yes

The following parameters can be set to a value or can be left blank:

- Destination IP
- Destination Port
- TOS ID

A wildcard TOS monitor (with destination IP, Destination port, and TOS ID not set) bound to a DSR service automatically learns the TOS ID and the VIP address of the load balancing virtual server. The monitor creates probe packets with the TOS field set to the encoded VIP address and then sends the probe packets to the server represented by the DSR service.

To create a wildcard TOS monitor by using the CLI

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add lb monitor <monitorName> <Type> -tos YES

show lb monitor <monitorName>
```

To bind a wildcard TOS monitor to a service by using the CLI

At the command prompt, type:

```
bind lb monitor <monitorName> <serviceName>

show lb monitor <monitorName>
```

To create a wildcard TOS monitor by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**.
2. Add a monitor with the following parameter settings:
   - Type = <protocol>
   - TOS = YES

To bind a wildcard TOS monitor to a service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Open a service and bind a wildcard TOS monitor to it.

In the following sample configuration, V1, V2, and V3 are load balancing virtual servers of type ANY and has TOS ID set to 1, 2, and 3 respectively. S1, S2, S3, S4, and S5 are services of type ANY. S1 and S2 are bound to both V1 and V2. S3, S4, and S5 and bound to both V1 and V3. WLCD-TOS-MON is a wildcard TOS monitor with type TCP and is bound to S1, S2, S3, S4, and S5.

WLCD-TOS-MON automatically learns the TOD ID and VIP address of virtual servers bound to S1, S2, S3, S4, and S5.

Because S1 is bound to V1 and V2, WLCD-TOS-MON creates two types of probe packets for S1, one with the **TOS** field set to the encoded VIP address (203.0.113.1) of V1 and the other with the VIP address (203.0.113.2) of V2. The Citrix ADC then sends these probe packets to the server represented by S1. Similarly, WLCD-TOS-MON creates probe packets for S2, S3, S4, and S5.

```
add lb monitor WLCD-TOS-MON  TCP -tos YES

Done

add lb vserver V1 ANY 203.0.113.1 * -m TOS  – tosID 1

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
Done

add lb vserver V2 ANY 203.0.113.2 * -m TOS  – tosID 2

Done

add lb vserver V3 ANY 203.0.113.3 * -m TOS  – tosID 3

Done

add service S1 198.51.100.1 ANY *

Done

add service S2 198.51.100.2 ANY *

Done

add service S3 198.51.100.3 ANY *

Done

add service S4 198.51.100.4 ANY *

Done

add service S5 198.51.100.5 ANY *

Done

bind lb monitor WLCD-TOS-MON S1

Done

bind lb monitor WLCD-TOS-MON S2

Done

bind lb monitor WLCD-TOS-MON S3

Done

bind lb monitor WLCD-TOS-MON S4

Done

bind lb monitor WLCD-TOS-MON S5

Done

bind lb vserver V1 S1, S2, S3, S4, S5

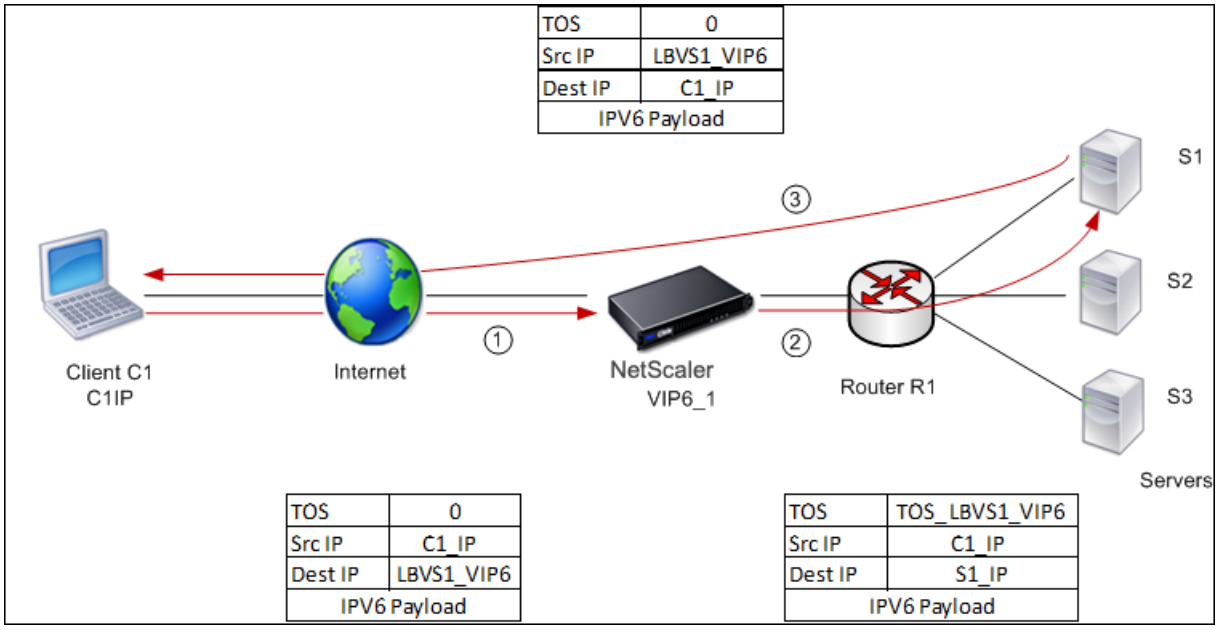
Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
60
61 bind lb vserver V2, S1, S2
62
63 Done
64
65 bind lb vserver V3 S3, S4, S5
66
67 Done
```

Use case 6: Configure load balancing in DSR mode for IPv6 networks by using the TOS field

September 14, 2021



You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the Citrix ADC appliance and the servers are in different networks.

Note: The TOS field is also called the Traffic Class field.

In DSR mode, when a client sends a request to a VIP6 address on a Citrix ADC appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the appliance.

Consider an example where a load balancing virtual server LBVS1, configured on a Citrix ADC appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The Citrix ADC appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following table lists the settings used in this example.

Entities	Name
IPv6 address of client C1	C1_IP (for reference purposes only)
Load balancing virtual server on NS1	LBVS1
IPv6 address of LBVS1	LBVS1_VIP6 (for references purpose only)
TOS value	TOS_LBVS1_VIP6 (for references purpose only)
Service for server S1 on NS1	SVC_S1
IPv6 address for server S1	S1_IP (for references purpose only)
Service for server S2 on NS1	SVC_S2
IPv6 address for server S1	S2_IP (for references purpose only)
Service for server S3 on NS1	SVC_S3
IPv6 address for server S1	S3_IP (for references purpose only)

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.
2. LBVS1's load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
   - TOS field set to TOS_LBVS1_VIP6.
   - Source IP address as C1_IP.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the appliance, with:
    - Source IP address set to the derivedLBVS1_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance

1. Enable USIP mode globally.
2. Add the servers as services.
3. Configure a load balancing virtual server with a TOS value.
4. Bind the services to the virtual server.

To configure load balancing in DSR Mode using TOS by using the command line interface

At the command prompt, type:

```
enable ns mode USIP

add service <serviceName> <IP> <serviceType> <port>
```

Repeat the earlier command as many times as necessary to add each server as a service on the Citrix ADC appliance.

```
add lb vserver <name> <serviceType> <ip> <port> -m <redirectionMode> -
    tosId <positive_integer>

bind lb vserver <vserverName> <serviceName>
```

To enable USIP mode by using the configuration utility

Navigate to **System > Settings > Configure Modes**, and select **Use Source IP Address**.

To create services by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services**, and create a service.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To create a load balancing virtual server and bind services by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a virtual server.
2. Click in the Service section to bind a service to this virtual server.

Use case 7: Configure load balancing in DSR mode by using IP Over IP

October 26, 2021

You can configure a Citrix ADC appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called *IP over IP* configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the Citrix ADC appliance. This improves response time and throughput. As with standard DSR mode, the Citrix ADC appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the Citrix ADC appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the Citrix ADC appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client. This is often referred to as L3DSR.

To configure L3-DSR mode on your Citrix ADC appliance:

- Create a load balancing virtual server. Set the mode to IPTUNNEL and enable sessionless tracking.
- Create services. Create a service for each back-end application and bind the services to the virtual server.
- Configure for decapsulation. Configure either a Citrix ADC appliance or a back-end server to act as a decapsulator.

  > Note:
  >
  > When you use a Citrix ADC appliance, the decapsulation setup is an IP tunnel between the ADC appliances with the back end doing L2DSR to the real servers.

Configure a load balancing virtual server

Configure a virtual server to handle requests to your applications. Assign the service type that matches the service, or use a type of ANY for multiple services.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Set the forwarding method to IPTUNNEL and enable the virtual server to operate in sessionless mode. Configure any load balancing method that you want to use.

To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

```
add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <
    port> -lbMethod <method> -m <ipTunnelTag> -sessionless [ENABLED |
    DISABLED]

show lb vserver <name>
```

Example:

In the following example, we have selected the load balancing method as sourceIPhash and configured sessionless load balancing.

```
add lb vserver Vserver-LB-1 ANY 1.1.1.80 * -lbMethod SourceIPHash -m
    IPTUNNEL -sessionless ENABLED
```

To create and configure a load balancing virtual server for IP over IP DSR by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Create a virtual server, and specify Redirection Mode as **IP Tunnel Based**.

Configure services for IP over IP DSR

After creating your load-balanced server, configure one service for each of your applications. The service handles traffic from the Citrix ADC appliance to those applications, and allows the Citrix ADC appliance to monitor the health of each application.

Assign the services to use USIP mode and bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add service <serviceName> <serverName> <serviceType> <port> -usip <usip
    >

add monitor <monitorName> <monitorType> -destip <ip> -iptunnel <
    iptunnel>

bind service <serviceName> -monitorName <monitorName>
```

Example:

In the following example, a monitor of type IPTUNNEL is created.

```
add monitor mon_DSR PING -destip 1.1.1.80 -iptunnel yes
add service svc_DSR01 2.2.2.100 ANY * -usip yes
bind service svc_DSR01 -monitorName mon_DSR
```

An alternative approach to simplify the routing at both the server and the ADC appliance is to setup both the ADC and server to use an IP from the same subnet. Doing so ensures that any traffic with a destination of a tunnel endpoint is sent over the tunnel. In the example, 10.0.1.0/30 is used.

> **Note:**
>
> The purpose of the monitor is to ensure that the tunnel is active by reaching the loopback of each server through the IP tunnel. If the service is not up, verify whether the outer IP routing between ADC and server is good. Also verify whether the inner IP addresses are reachable through the IP tunnel. Routes might be required on the server, or PBR is added to ADC depending on the chosen implementation.

Example:

```
add ns ip 10.0.1.2 255.255.255.252 -vServer DISABLED
add netProfile netProfile_DSR -srcIP 10.0.1.2
add lb monitor mon_DSR PING -LRTM DISABLED -destIP 1.1.1.80 -ipTunnel
    YES -netProfile netProfile_DSR
```

To configure a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor, and select **IP Tunnel**.

To create and configure a service for IP over IP DSR by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Create a service and, in **Settings** tab, select **Use Source IP Address**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt type the following command:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver Vserver-LB-1 Service-DSR-1
```

To bind a service to a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the **Services** section to bind a service to the virtual server.

Using the client IP address in the Outer header of tunnel packets

The Citrix ADC supports using the client-source IP address as the source IP address in the outer header of tunnel packets related to direct server return mode using IP tunneling. This feature is supported for DSR with IPv4 and DSR with IPv6 tunneling modes. For enabling this feature, enable the **use client source IP address** parameter for IPv4 or IPv6. This setting is applied globally to all the DSR configurations that use IP tunneling.

To use a client-source IP address as the source IP address by using the CLI

At the command prompt, type:

- `set iptunnelparam -useclientsourceip [YES | NO]`
- `show iptunnelparam`

To use client source IP address as the source IP address by using the GUI

1. Navigate to **System > Network**.
2. In **Settings** tab, click **IPv4 Tunnel Global Settings**.
3. In the **Configure IPv4 Tunnel Global Parameters** page, select **Use Client Source IP** check box.
4. Click **OK**.

To use client source IP address as the source IP address by using the CLI

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- `set ip6tunnelparam -useclientsourceip [YES | NO]`
- `show ip6tunnelparam`

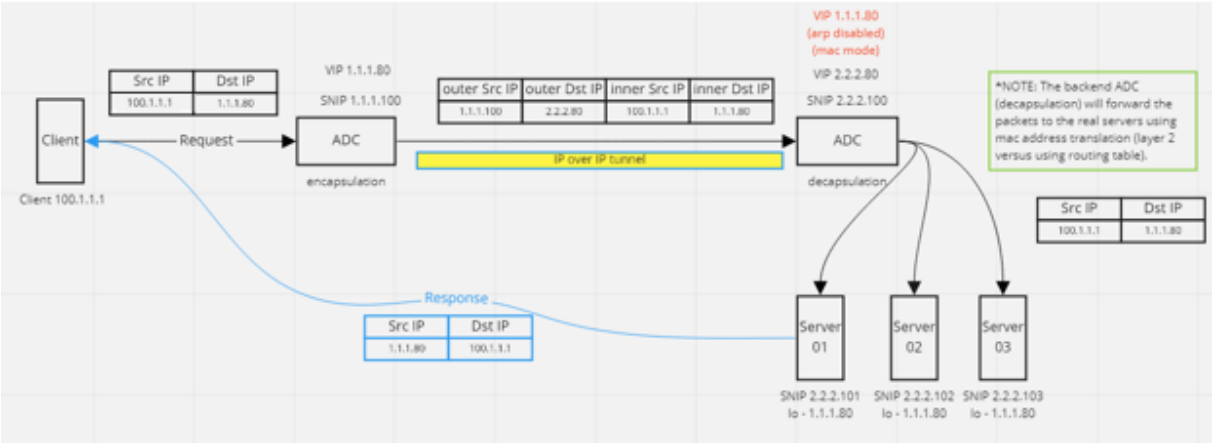
To use client source IP address as the source IP address by using the GUI

1. Navigate to **System > Network**.
2. In **Settings** tab, click **IPv6 Tunnel Global Settings**.
3. In the **Configure IPv6 Tunnel Global Parameters** page, select **Use Client Source IP** check box.
4. Click **OK**.

Decapsulation configuration

You can configure either a Citrix ADC appliance or a back-end server as a decapsulation.

Citrix ADC decapsulation



When a Citrix ADC appliance is used as a decapsulation, an IP tunnel must be created in the Citrix ADC appliance. For more details, see Configuring IP Tunnels.

The Citrix ADC decapsulation setup consists of the following two virtual servers:

- The first virtual server receives the encapsulated packet and removes the outer IP encapsulation.
- The second virtual server has the IP of the original service on the front-end ADC and uses MAC translation to forward the packet towards the back end by using the MAC address of the bound services. This setup is typically known as L2DSR. Ensure to disable ARP on this virtual server.

Example setup:

The following illustration shows a decapsulation setup using the ADC appliances.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The complete configuration required for the setup is as follows.

Front-end ADC configuration:

```
add service svc_DSR01 2.2.2.80 ANY * -usip YES -useproxyport NO
add lb vserver vip_DSR_ENCAP ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
    IPTUNNEL -sessionless ENABLED
bind lb vserver vip_DSR_ENCAP svc_DSR01
```

Back-end ADC configuration:

```
add ipTunnel DSR-IPIP 1.1.1.100 255.255.255.255 *

add service svc_DSR01_01 2.2.2.101 ANY * -usip YES -useproxyport NO
add service svc_DSR01_02 2.2.2.102 ANY * -usip YES -useproxyport NO
add service svc_DSR01_03 2.2.2.103 ANY * -usip YES -useproxyport NO

add lb vserver vs_DSR_DECAP ANY 2.2.2.80 * -lbMethod SOURCEIPHASH -m
    IPTUNNEL -sessionless ENABLED -netProfile netProf_DSR_MBF_noIP

add ns ip 1.1.1.80 255.255.255.255 -type VIP -arp DISABLED -snmp
    DISABLED
add lb vserver vs_DSR_Relay ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
    MAC -sessionless ENABLED

bind lb vserver vs_DSR_DECAP svc_DSR01_01
bind lb vserver vs_DSR_DECAP svc_DSR01_02
bind lb vserver vs_DSR_DECAP svc_DSR01_03

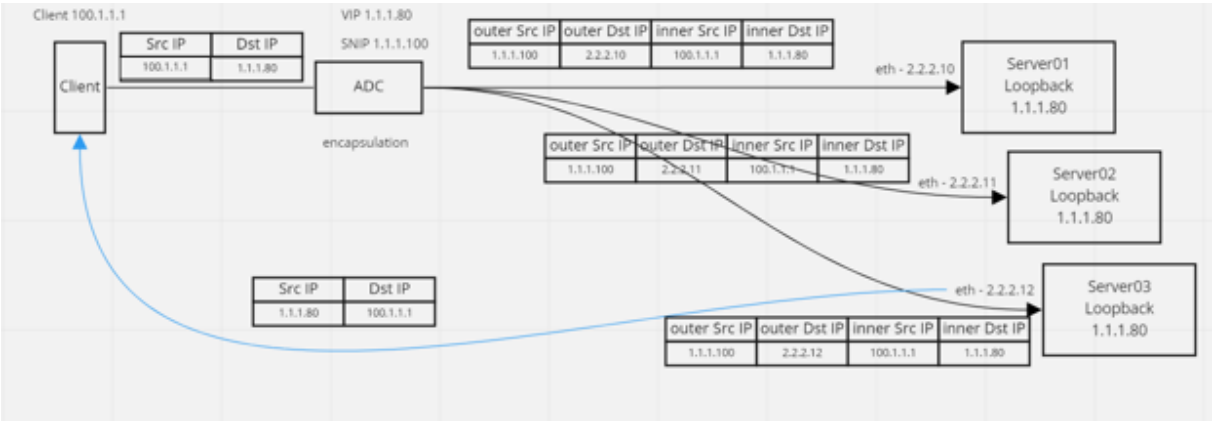
bind lb vserver vip_DSR_Relay svc_DSR01_01
bind lb vserver vip_DSR_Relay svc_DSR01_02
bind lb vserver vip_DSR_Relay svc_DSR01_03

add netProfile netProf_DSR_MBF_noIP -MBF ENABLED
add lb monitor mon_DSR_MAC PING -netProfile netProf_DSR_MBF_noIP
bind service svc_DSR01_01 -monitorName mon_DSR_MAC
bind service svc_DSR01_02 -monitorName mon_DSR_MAC
bind service svc_DSR01_03 -monitorName mon_DSR_MAC
```

The following example shows a testing setup using Ubuntu and Red Hat servers running apache2. These commands are set up on each back-end server.

```
sudo ip addr add 1.1.1.80 255.255.255.255 dev lo
sudo sysctl net.ipv4.conf.all.arp_ignore=1
sudo sysctl net.ipv4.conf.all.arp_announce=2
sudo sysctl net.ipv4.conf.eth4.rp_filter=2 (The interface has the
    external IP with route towards the ADC)
sudo sysctl net.ipv4.conf.all.forwarding=1
sudo ip link set dev lo arp on
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



Back-end server decapsulation

When you use the back-end servers as a decapsulation, the back-end configuration varies depending upon the server OS type. You can configure a back-end server as a decapsulation by following these steps:

1. Configure a loop back interface with IP for service IP.
2. Create a tunnel interface.
3. Add a route through tunnel interface.
4. Configure interface settings as required for traffic.

> Note:
>
> Windows OS servers cannot do IP tunneling natively, so the commands are provided as examples for Linux based systems. Third-party plug-ins are available for Windows OS servers, however, that is outside the scope of this example.

The following illustration shows a decapsulation setup using the back-end servers.

Example configuration:

In this example, 1.1.1.80 is the Citrix ADC virtual IP (VIP) address and 2.2.2.10-2.2.2.12 are the back-end server IP addresses. The VIP address is configured in the loopback interface, and a route is added through the tunnel interface. The monitors use the server IP, and tunnel the monitor packets over the IP tunnel using the tunnel endpoints.

The complete configuration required for the setup is as follows.

Front-end ADC configuration:

The following configuration creates a monitor that uses the tunnel endpoint as source. Then, send pings over tunnel to service IP address.

```
add ns ip 10.0.1.2 255.255.255.252 -vServer DISABLED
add netProfile netProfile_DSR -srcIP 10.0.1.2
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
3 add lb monitor mon_DSR PING -LRTM DISABLED -destIP 1.1.1.80 -ipTunnel
     YES -netProfile netProfile_DSR
```

The following configuration creates a VIP for service that uses the original source IP address. Then, forwards traffic over IP tunnel to back-end servers.

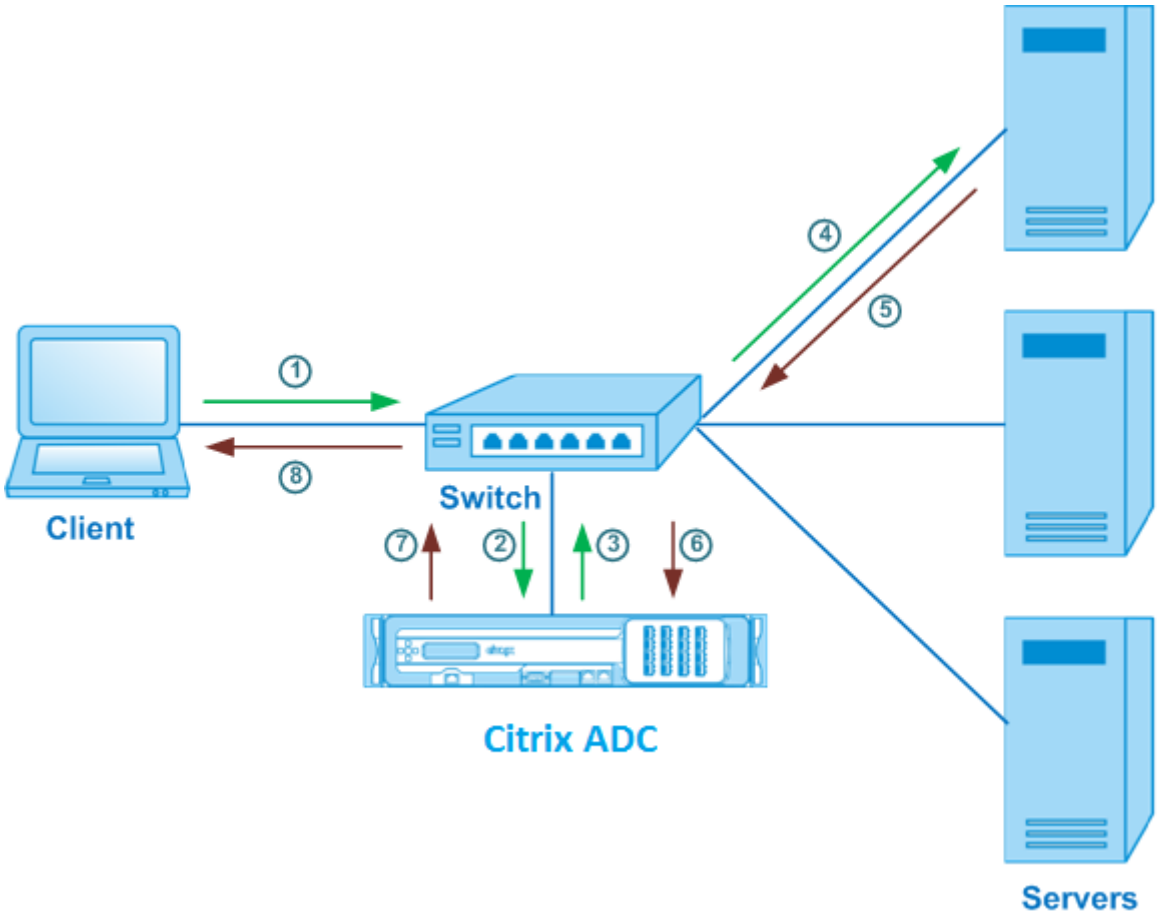
```
1  add service svc_DSR01 2.2.2.10 ANY * -usip YES -useproxyport NO
2  bind service svc_DSR01 -monitorName mon_DSR
3
4  add service svc_DSR02 2.2.2.11 ANY * -usip YES -useproxyport NO
5  bind service svc_DSR02 -monitorName mon_DSR
6
7  add service svc_DSR03 2.2.2.12 ANY * -usip YES -useproxyport NO
8  bind service svc_DSR03 -monitorName mon_DSR
9
10 add lb vserver vip_DSR_ENCAP ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
     IPTUNNEL -sessionless ENABLED
11 bind lb vserver vip_DSR_ENCAP svc_DSR01
12 bind lb vserver vip_DSR_ENCAP svc_DSR02
13 bind lb vserver vip_DSR_ENCAP svc_DSR03
```

Back-end server configuration of each server:

The following commands are required for the back-end server to receive the IPIP packet, remove the outer encapsulation, then respond from the loopback to the original client IP. Doing so ensures the IP addresses in the packet received by the client match the IP addresses in the original request.

```
1  modprobe ipip
2  sudo ip addr add 1.1.1.80 255.255.255.255 dev lo
3  nmcli connection add type ip-tunnel ip-tunnel.mode ipip con-name tun0
4  ifname tun0 remote 198.51.100.5 local 203.0.113.10
5  nmcli connection modify tun0 ipv4.addresses '10.0.1.1/30'
6  nmcli connection up tun0
7  sudo sysctl net.ipv4.conf.all.arp_ignore=1
8  sudo sysctl net.ipv4.conf.all.arp_announce=2
9  sudo sysctl net.ipv4.conf.tun0.rp_filter=2
10 sudo sysctl net.ipv4.conf.all.forwarding=1
11 sudo ip link set dev lo arp off
```

Use case 8: Configure load balancing in one-arm mode



August 16, 2023

In a one-arm setup, you connect the Citrix ADC appliance to the network through a single VLAN. The appliance receives the request from the client on a single VLAN and it sends the request to the server on the same VLAN. This is one of the simplest deployment scenarios, where the router, the servers and

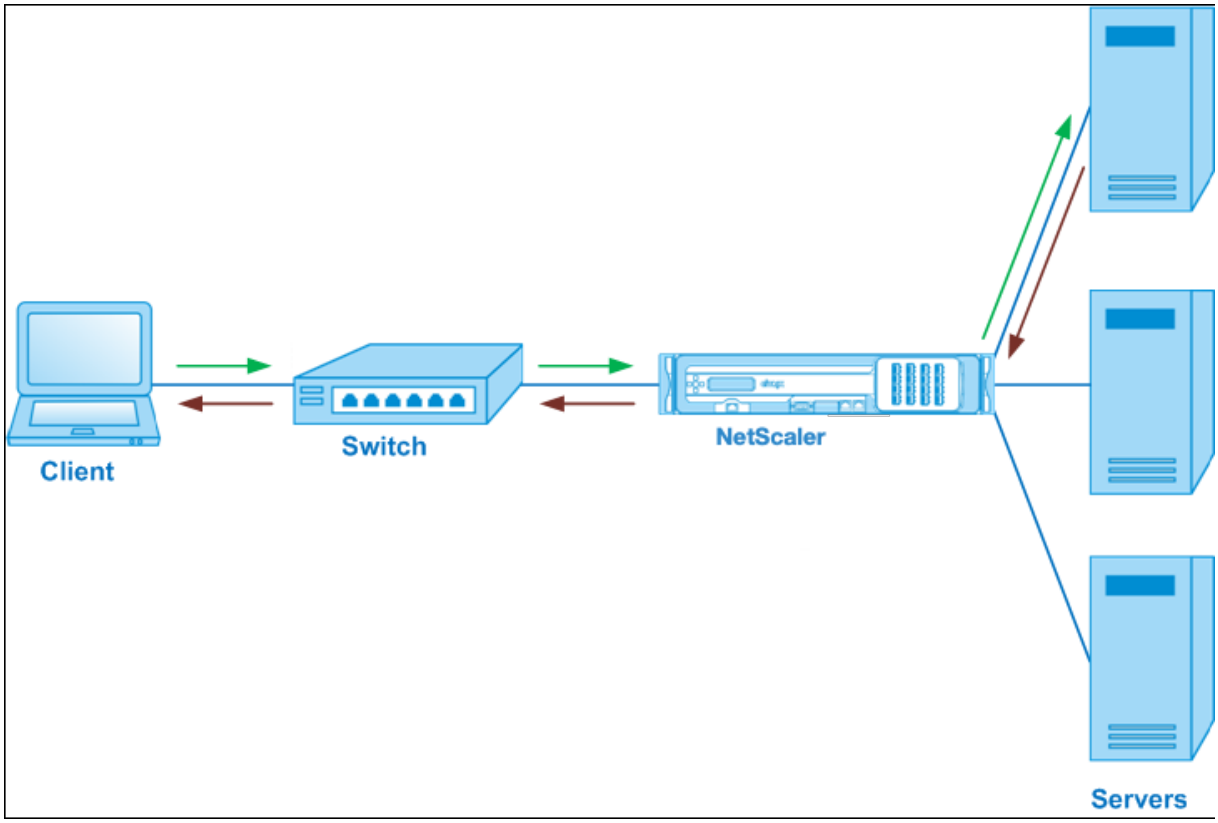
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

the appliance are all connected to the same switch. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service.

Figure 1. Load balancing in one-arm mode

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY
	Service-ANY-3	10.102.29.93	ANY
Monitors	TCP	None	None



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

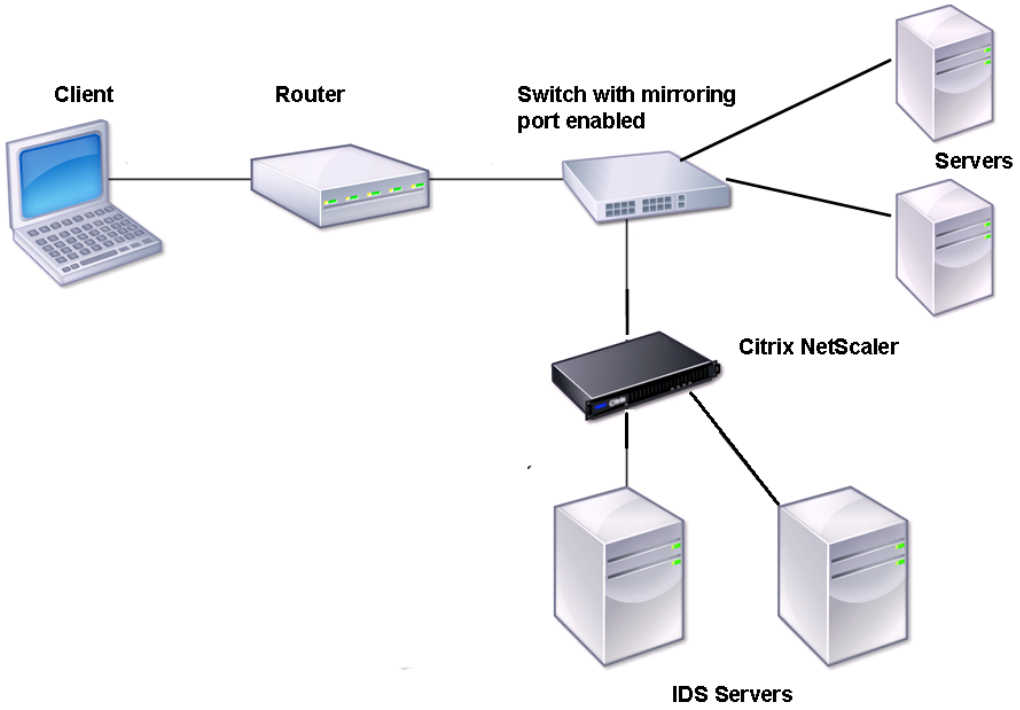
To configure a load balancing setup in one-arm mode, see Setting Up Basic Load Balancing.

Use case 9: Configure load balancing in the inline mode

September 14, 2021

In an inline mode (also called two-arm mode) setup, you connect the Citrix ADC appliance to the network through multiple VLANs. The appliance receives the request from the client on one VLAN and it sends the request to the server on another VLAN. In the two-arm setup, the appliance is connected between the servers and the client. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service.

The configuration and the entity diagram for inline mode are the same as described in Configuring Load Balancing in One-arm Mode.



Use case 10: Load balancing of intrusion detection system servers

August 16, 2023

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable the Citrix ADC appliance to support load balancing of intrusion detection system (IDS) servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch, the request packets are copied or sent to the Citrix ADC appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

Figure 1. Topology of Load Balanced IDS Servers

Note: Currently, the appliance supports load balancing of passive IDS devices only.

As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

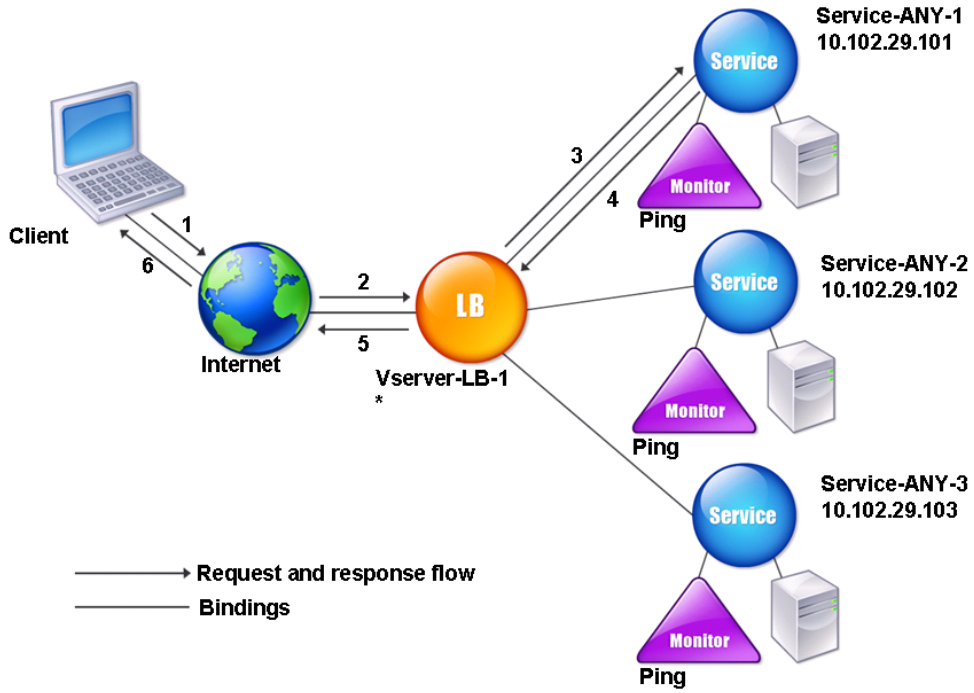
1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.
2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

IDS server.

Note: When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets flowing from the client to a service on the appliance must be sent to a single IDS server.

Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.



Entity type	Name	IP address	Port	Protocol
Virtual server	Vserver-LB-1	*	*	ANY
Services	Service-ANY-1	10.102.29.101	*	ANY
	Service-ANY-2	10.102.29.102	*	ANY
	Service-ANY-3	10.102.29.103	*	ANY
Monitors	Ping	None	None	None

Note: You can use inline mode or one-arm mode for an IDS load balancing setup.

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 2. Entity Model for Load Balancing IDS Servers

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure an IDS load balancing setup, you must first enable MAC-based forwarding. Also disable layer 2 and layer 3 modes on the appliance.

To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

```
enable ns mode <ConfigureMode>
```

Example:

```
enable ns mode MAC
```

To enable MAC-based forwarding by using the configuration utility

Navigate to **System > Settings > Configure Modes**, and select **MAC Based Forwarding**.

Next, see "Setting Up Basic Load Balancing", to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

To configure a load balancing method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <
    RedirectionMode> -sessionless <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPDestIPHash -m MAC -
    sessionless enabled
```

> **Note**
>
> For a service that is bound to a virtual server on which the -m MAC option is enabled, you must bind a non-user monitor.

To configure a load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and, in Redirection Mode, select MAC Based.
3. In Advanced Settings, click Methods, and select SRCIPDESTIPHASH. Click Traffic Settings, and select Sessionless Load Balancing.

To set a service to use the source IP address by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
```

Example:

```
set service Service-ANY-1 -usip yes
```

To set a service to use the source IP address by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. Open a service, and in Settings select **Use Source IP Address**.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see IP Addressing.

Use case 11: Isolating network traffic using listen policies

September 14, 2021

> **Note**
>
> The traffic isolation solution using shadow virtual servers to simulate multitenant isolation is no more recommended. Alternatively, Citrix recommends you to use the Citrix ADC Admin Partitioning feature for such deployments. For more information, see Admin Partitioning.

A common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant's traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department's applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IdP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multitenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a Citrix ADC appliance identifies the network domains and controls the traffic across the domains. The Citrix ADC solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified network domain.

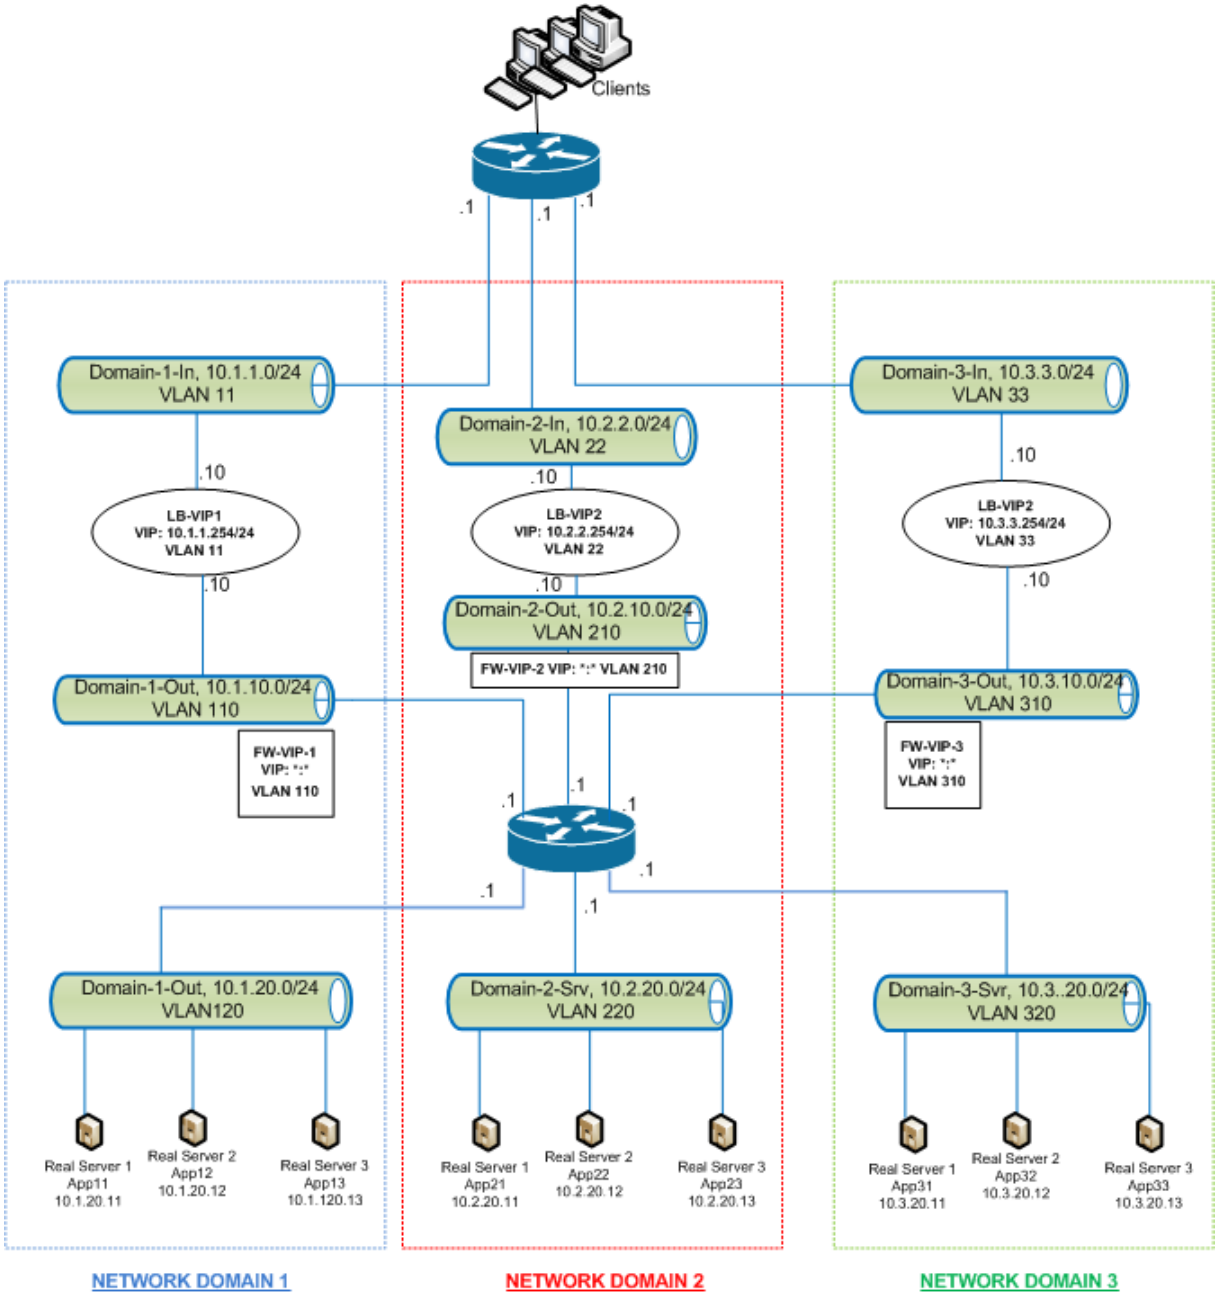
To isolate the traffic, listen policies can be based on several client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Category	Parameters
Ethernet protocol	Source MAC address, destination MAC address
Network interface	Network ID, receiving throughput, sending throughput, transmission throughput
IP protocol	Source IP address, destination IP address
IPv6 protocol	Source IPv6 address, destination IPv6 address
TCP protocol	Source port, destination port, maximum segment size, payload, and other options
UDP protocol	Source port, destination port
VLAN	ID

Table 1. Client Parameters Used to Define Listen Policies

On the Citrix ADC appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (*) IP address and port, and its service type is set to ANY.



In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

How network paths are isolated

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network Domain 1 and Network Domain 2.

Figure 1. Isolating Network Path

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Traffic within network domain 1

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the Citrix ADC for all the traffic that originates from a client.

Traffic between network domain 1 and network domain 2

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANS: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VALN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.
- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.

Configuration Steps

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic.
- For each network domain, configure two virtual servers as follows:
  - Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create an expression while creating the virtual server.
  - Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

this virtual server, set the service type to ANY and the IP address and port to an asterisk (*). Enable MAC-based forwarding on this virtual server.

- Enable the L2 Connection option on both the virtual servers.

  Generally, to identify a connection, the Citrix ADC appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

- Add services representing the server pools in the domain, and bind them to the virtual server.
- Configure the firewall for each domain as a service, and bind all the firewall services to the shadow virtual server.

To isolate network traffic by using the command line interface

At the command prompt, type the following commands:

```
add policy expression <expressionName> <listenPolicyExpression>

add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -
   listenPolicy <expressionName>
```

Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.

```
add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <
   expressionName>
```

Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

Example:

```
add policy expression e110 client.vlan.id==110
add policy expression e210 client.vlan.id==210
add policy expression e310 client.vlan.id==310
add policy expression e11 client.vlan.id==11
add policy expression e22 client.vlan.id==22
add policy expression e33 client.vlan.id==33

add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -persistenceType NONE -
   listenPolicy e11
-cltTimeout 180 -l2Conn ON

add lb vserver LB-VIP2 HTTP 10.2.2.254 80 -persistenceType NONE -
   listenPolicy e22
-cltTimeout 180 -l2Conn ON

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
14 add lb vserver LB-VIP3 HTTP 10.3.3.254 80 -persistenceType NONE -
      listenPolicy e33
15 -cltTimeout 180 -l2Conn ON
16
17
18 add lb vserver FW-VIP-1 ANY * * -persistenceType NONE -lbMethod
      ROUNDROBIN - listenPolicy e110 -Listenpriority 1 -m MAC -cltTimeout
      120
19
20 add lb vserver FW-VIP-2 ANY * * -persistenceType NONE -lbMethod
      ROUNDROBIN - listenPolicy e210 -Listenpriority 2 -m MAC -cltTimeout
      120
21
22 add lb vserver FW-VIP-3 ANY * * -persistenceType NONE -lbMethod
      ROUNDROBIN - listenPolicy e310 -Listenpriority 3 -m MAC -cltTimeout
      120
23
24
25 add service RD-1 10.1.1.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
      DISABLED
26 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
      NO -TCPB NO -CMP NO
27
28 add service RD-2 10.2.2.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
      DISABLED
29 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
      NO -TCPB NO -CMP NO
30
31 add service RD-3 10.3.3.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
      DISABLED
32 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
      NO -TCPB NO -CMP NO
33
34
35 bind lb vserver FW-VIP-1 RD-1
36
37 bind lb vserver FW-VIP-2 RD-2
38
39 bind lb vserver FW-VIP-3 RD-3
```

To isolate network traffic by using the configuration utility

1. Add services representing the servers, as described in Creating a Service.
2. Add each firewall as a service:
   a) Navigate to **Traffic Management > Load Balancing > Services**.
   b) Create a service, specifying the protocol as ANY, server as firewall's IP address, and port as 80.
3. Configure a load balancing virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. Configure the shadow load balancing virtual server.
5. For each network domain, repeat steps 3 and 4.
6. From the Load Balancing Virtual Servers pane, open the virtual servers that you created and verify the settings.

Use case 12: Configure XenDesktop for load balancing

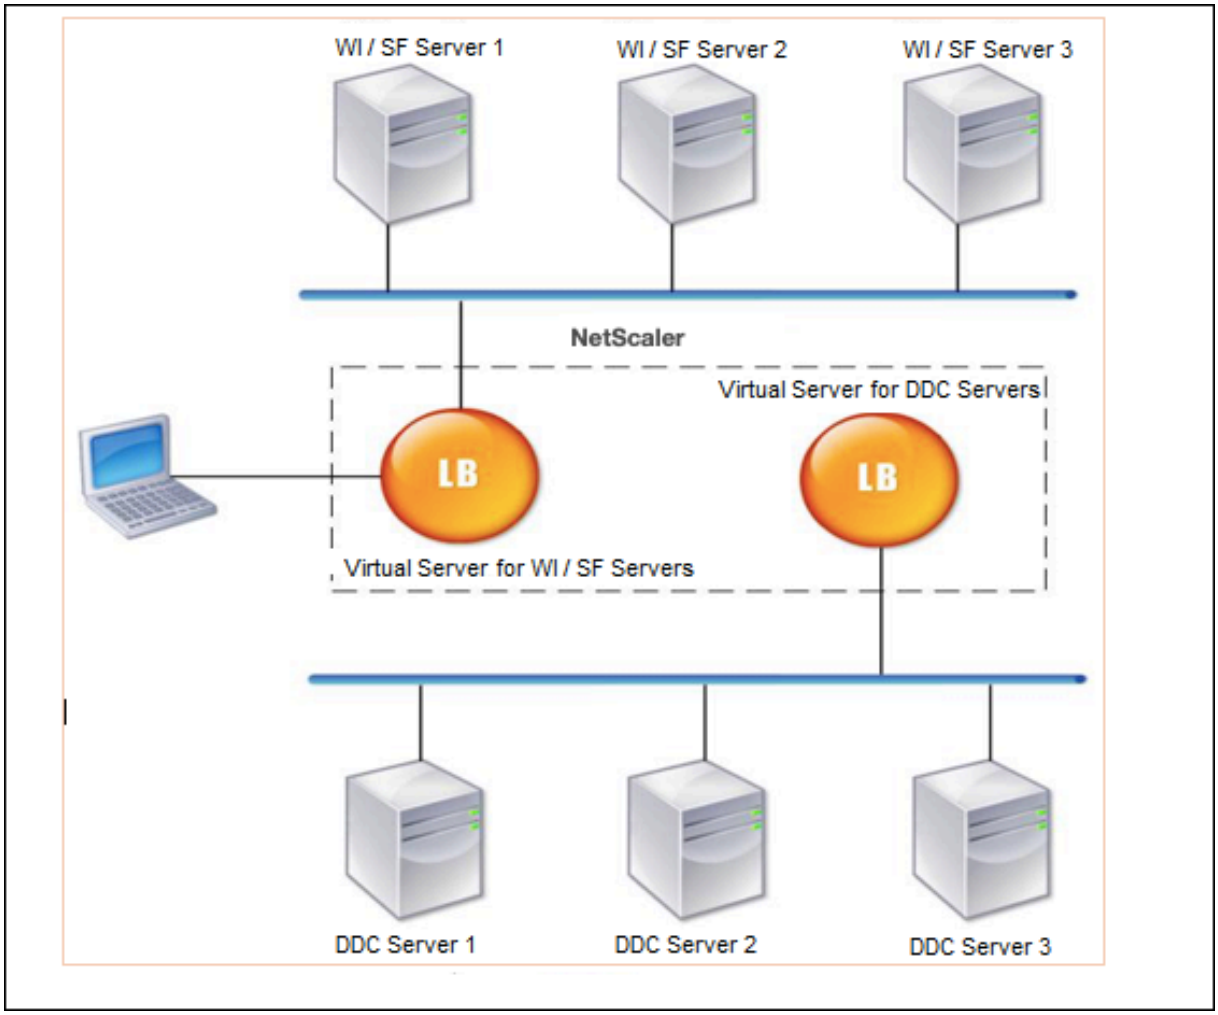
December 8, 2022

For an improved performance in the delivery of virtual desktop applications, you can integrate the Citrix ADC appliance with Citrix XenDesktop and use the Citrix ADC load balancing feature to distribute the load across the Web Interface servers and the Desktop Delivery Controller (DDC) servers.

Generally, you use XenDesktop in situations where applications are not compatible with running on a terminal server or Citrix Virtual Apps, or if each virtual desktop has unique requirements. In such cases, you need one desktop host for each user that connects. However, the hosts can be pooled so that you need only one host for each currently connected user.

The core application service deployed for XenDesktop is the Desktop Delivery Controller (DDC). The DDC is installed on a server, and its main function is to register desktop hosts and broker client connections to them.

The DDC also authenticates users and manages the assembly of the users' virtual desktop environments by controlling the state of the desktops, and starting and stopping the desktops.



Generally, multiple DDCs are installed to enhance availability.

The Web Interface servers provide secure access to virtual desktops. The Web Interface is the initial connection portal to the Desktop Delivery Controller (DDC). The Web browser on the user's device sends information to the Web server, which communicates with the server farm to provide the user with access to the virtual desktop.

The following figure shows the topology of a Citrix ADC appliance working with XenDesktop.

Figure 1. Load Balancing of XenDesktop

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note

Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the Citrix ADC appliance. You can use the HTTP protocol for communication between the Citrix ADC and the DDC servers even though you use the SSL protocol for communication with the client.

To configure load balancing for XenDesktop by using the GUI

1. Create a service.
    a) Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
    b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

a) Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and click **Add**.
b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click **OK**.

3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and select a server.

a) Click **Edit**.
b) In the **Services and Service Groups**, click **>** and click **Add Binding**.
c) Select the service you want to bind and enter the weight value.
d) Click **Bind**.

To configure load balancing for XenDesktop by using the command line interface

- To create a service, at the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
```

Example:

```
add service Service-HTTP-1 192.0.2.5 HTTP 80
```

- To create a virtual server, at the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>
```

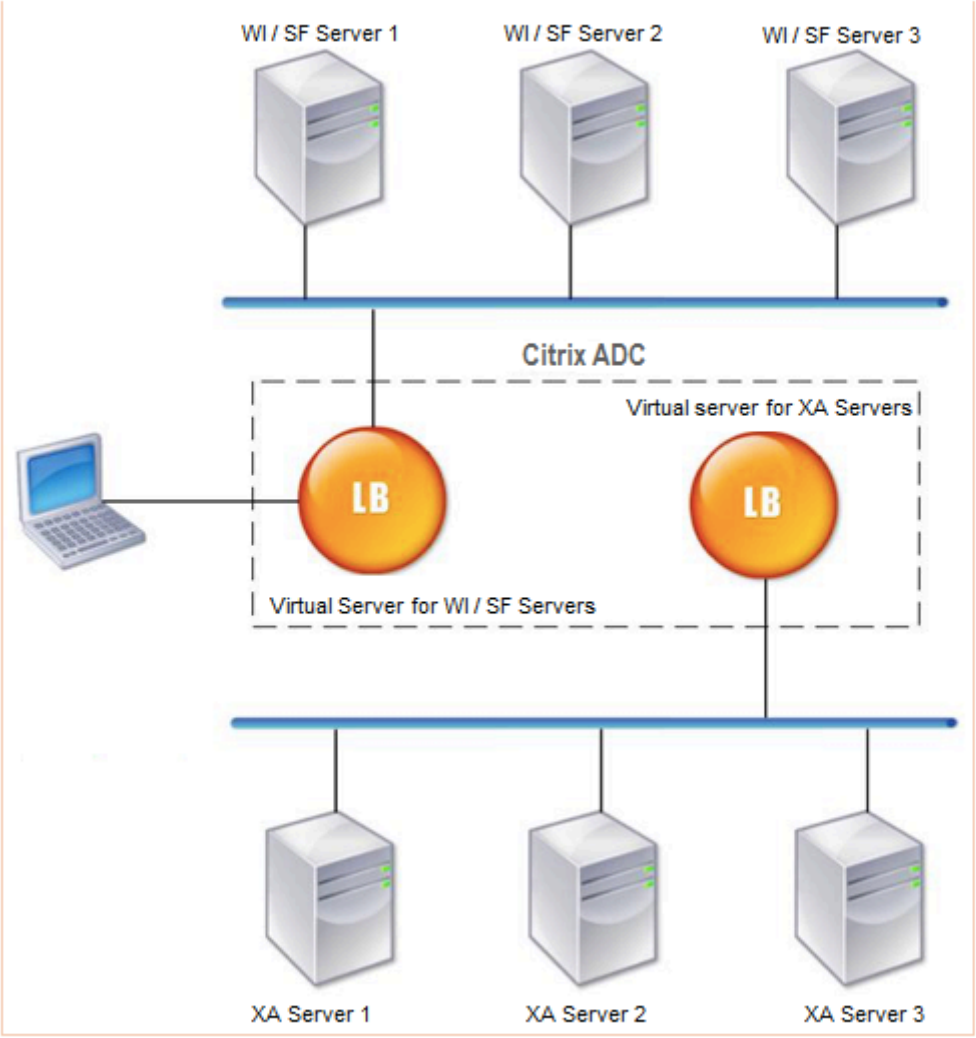
Example:

add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80

- To bind a service to a load balancing virtual server, at the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

Example:



```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

Use case 13: Configure Citrix Virtual Apps for load balancing

October 11, 2023

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For efficient delivery of applications, you can integrate the Citrix ADC appliance with Citrix Virtual Apps and use the Citrix ADC load balancing feature to distribute the load across the Citrix Virtual Apps server farms. The following figure is a topology diagram of such a setup.

The Web Interface servers provide secure access to Citrix Virtual Apps application resources through the user's Web browser. The Web Interface client presents to the users all the resources, such as applications, content, and desktops that are made available in the Citrix Virtual Apps server farms. Users can access the published resources through a standard Web browser or through the Citrix online plug-in.

The Web browser on the user's device sends information to the Web server, which communicates with the servers on the server farm to provide the user with access to the resources.

The Web Interface and the XML Broker are complementary services. The Web Interface provides users with access to applications, and the XML Broker evaluates the user's permissions to determine which

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

applications appear in the Web Interface.

The XML service is installed on all the servers in the server farm. The XML service specified in the Web Interface functions as an XML broker. Based on the user credentials passed by the Web Interface server, the XML Broker server sends a list of applications accessible to the user.

In large enterprises where multiple Web Interface servers and XML Broker servers are deployed, Citrix recommends load balancing these servers by using the Citrix ADC appliance. Configure one virtual server to load balance the Web Interface servers and another for the XML Broker servers. The load balancing method and other features can be configured on the virtual server as required.

> **Note**
>
> Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the Citrix ADC. You can use the HTTP protocol for communication between the Citrix ADC and the WI servers even though you use the SSL protocol for communication with the client.

To configure load balancing for Citrix Virtual Apps by using the GUI

1. Create a service.
    a) Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
    b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.
    a) Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and click **Add**.
    b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and select a server.
    a) Click **Edit**.
    b) In the **Services and Service Groups**, click **>** and click **Add Binding**.
    c) Select the service you want to bind and enter the weight value.
    d) Click **Bind**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure load balancing for Citrix Virtual Apps by using the command line interface

- To create a service, at the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
```

Example:

```
add service Service-HTTP-1 192.0.2.5 HTTP 80
```

- To create a virtual server, at the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>
```

Example:

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

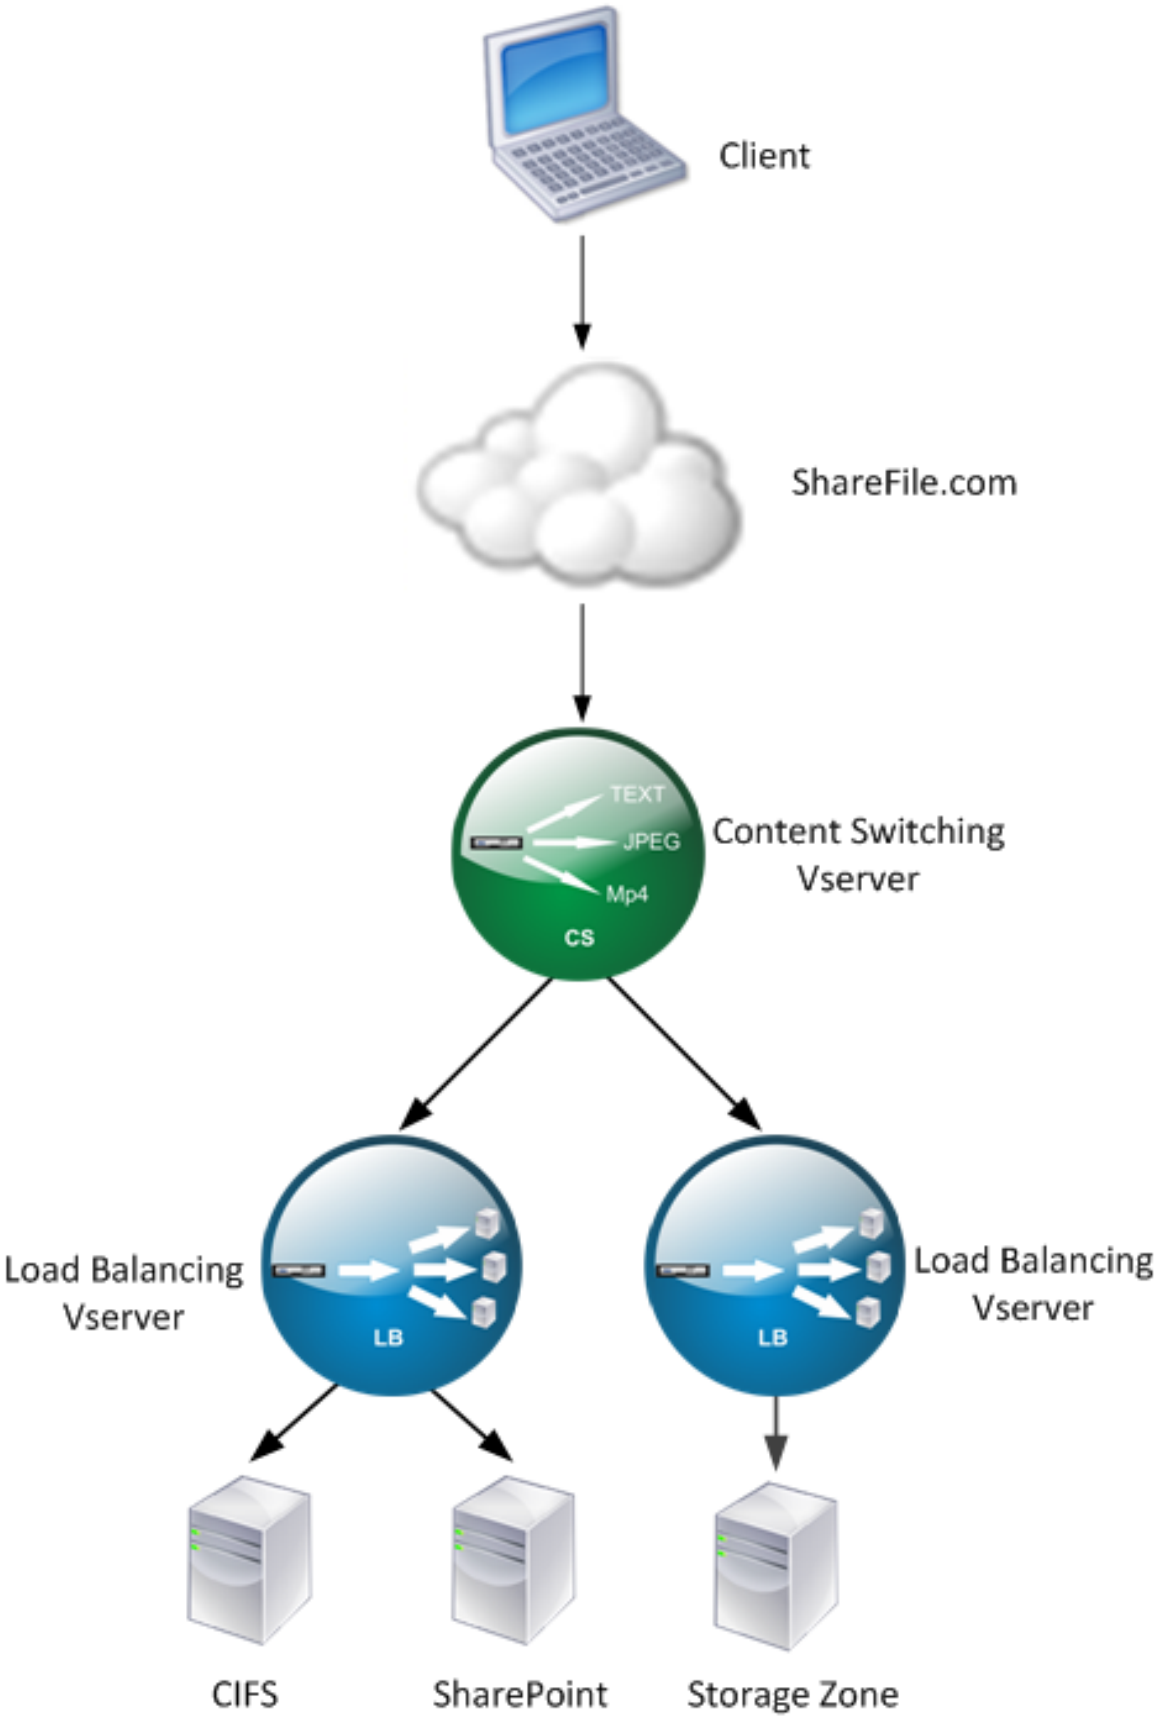
- To bind a service to a load balancing virtual server, at the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

Use case 14: ShareFile wizard for load balancing Citrix ShareFile



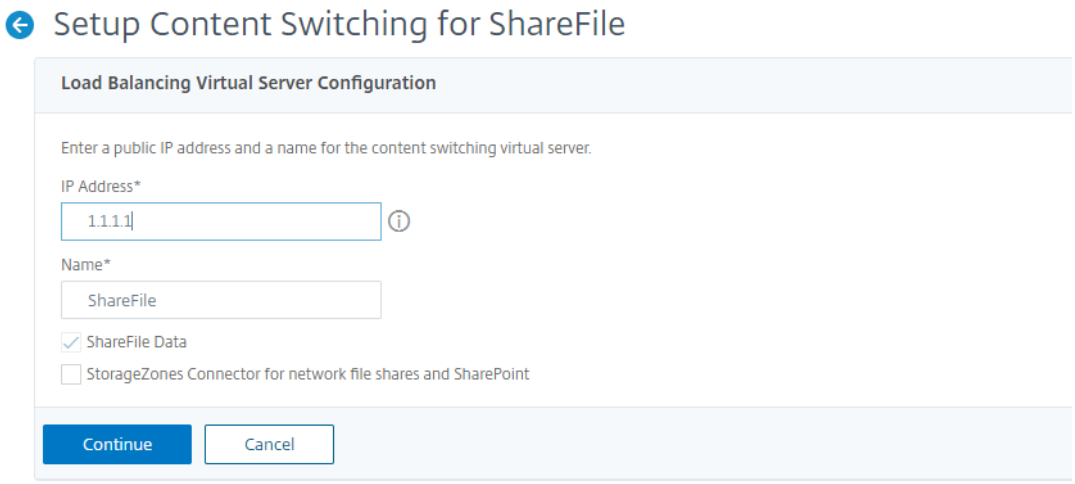
October 16, 2023

You can configure load balancing for Citrix ShareFile using the wizard. The Citrix ShareFile wizard helps in setting up the load balancing configuration for the ShareFile site based on the type of content requested. The content switching server directs the request based on whether it is a StorageZone, CIFS, or a SharePoint request. The content switching is based on policies. The wizard auto generates the policies to identify whether the request is for StorageZone, CIFS, or SharePoint. The content switching virtual server uses these policies to direct the request to the correct load balancing server.

A typical data flow can be depicted as shown in the following diagram.

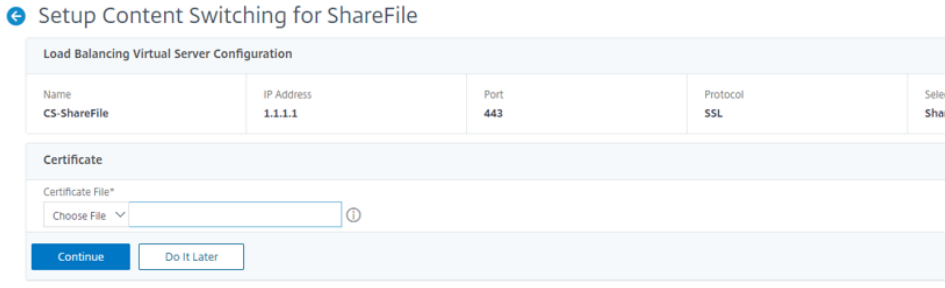
Figure 1. ShareFile Data Load Balancing

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

You can view the load balancing virtual servers that the ShareFile wizard creates by navigating to **Traffic Management > Virtual Servers** and **Services > Virtual Servers**. You cannot manually remove the virtual servers created using the ShareFile wizard. Use the wizard to remove the virtual servers.



Citrix ADC uses the LDAP authentication for SharePoint or CIFS request. Hash authentication is used for authenticating requests for StorageZones.

To configure a Citrix ADC appliance for load balancing Citrix ShareFile

1. In the navigation pane, click **Traffic Management**.
2. Under **Citrix ShareFile** section, click **Setup Citrix ADC for ShareFile**.
3. On the **Setup Content Switching for ShareFile** page, provide the following information:
   - IP Address: IP address of the content switching virtual server.
   - Name: Name of the content switching virtual server.
   - If you want to set up load balancing for CIFS or SharePoint, click the **StorageZone Connector for Network File Shares/SharePoint** check box and then click **Continue**. By default, the **ShareFile Data** check box is selected.

4. Provide a valid certificate. If you have a certificate, click **Choose Certificate** and from the drop-down list select the certificate. If you have to install a certificate, click **Install Certificate** and provide the Certificate-Key pair.

5. Click **Continue**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

6. In the **Add New StorageZone Controller** dialog box, specify the values of the following parameters:

   - StorageZone Controller IP Address—IP address
   - Port—Port number. The default value is 443.
   - Protocol—Select from HTTPS or HTTP

7. Click **Create** and then click **Done**. The wizard automatically creates a service and autogenerates the name of the service.
8. If you chose load balancing for CIFS or SharePoint in step 4.c, then specify the values for LDAP Authentication Settings:

   - Citrix ADC AAA virtual server IP Address—IP address of Citrix ADC AAA virtual server
   - LDAP Server IP Address—IP Address of the LDAP server
   - Port—Port number. The default value is 389
   - Timeout—The time-out value in minutes
   - Single sign-on Domain—Single sign-on domain name
   - Base DN—Base domain name
   - Administrator Bind DN—LDAP account name with the domain name, for example, administrator@domainname.com
   - Logon Name—Logon name is the sAMAccountName
   - Password and Confirm Password—Enter the password and confirm the password

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

9. Click **Continue** and then click **Done**.

To remove load balancing configuration for ShareFile

1. In the navigation pane, click **Traffic Management**.
2. Under **Citrix ShareFile** section, click **Remove ShareFile Configuration**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Use case 15: Configure layer 4 load balancing on the Citrix ADC appliance

October 8, 2023

The layer 4 load balancer (TCP and UDP ports) uses information provided in the networking transport layer for routing client requests across the server groups.

When a layer 4 connection is established between a client and a server, it has a packet view of traffic exchanged between them. The layer 4 load balancer makes its routing decisions based on the address information extracted from the first few packets in the TCP stream, and doesn't inspect the packet content. Therefore, the layer 4 load balancing is also called as connection-based load balancing.

The layer 4 load balancer monitors the health of a server. Traffic is not routed to the server if it is DOWN.

The layer 4 load balancing is useful for various applications that uses TCP or UDP payloads. Such protocols exchange data as TCP payload and don't have a specific structure to follow.

To configure layer 4 load balancing using the command line interface

At the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
add lb vserver <name> <serviceType> <ip> <port>
bind lb vserver <name> <serviceName>
```

Example:

```
add service TCPservice 192.0.2.3 TCP 1
add lb vserver TCPserver TCP 192.0.2.4 1
bind lb vserver TCPserver TCPservice
```

To configure layer 4 load balancing using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Click **Add** to a create a service.
3. Specify the required details in **Service Name** and **IP Address**.
4. Select either **TCP** or **UDP** in **Protocol**.
5. Click **OK**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

6. Click **Done**.

   A service is created.

   When you create a service using UDP as the transport layer protocol, a ping monitor (built-in monitor) is automatically bound to the service. When you create a service using TCP as the transport layer protocol, a **tcp_default** monitor is automatically bound to the service.

   For the load balancing setup, you can bind your service to a different type of monitor or multiple monitors. For advance monitoring requirements you can use the **tcp-ecv** monitor and configure the request and response messages.

7. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
8. Click **Add** to create a new virtual server.

   When the load balancing is configured, you can connect to the load-balanced website, application, or server through the virtual server's IP address or FQDN.

9. Specify the required details in **Name**, **IP Address Type**, and **IP Address**.
10. Select either **TCP** or **UDP** in **Protocol**.
11. Type a port number (0–1023 based on the type of service) in **Port**.
12. Click **OK**.
13. Click **No Load Balancing Virtual Server Service Binding** in **Services and Service Groups**.
14. In the **Service Binding** page, select **Click to Select** in **Select Service**.
15. Select the service to be bound and click **Select**.
16. Click **Bind** to bind the service to the virtual server.
17. Click **Continue**.
18. Click **Done**.

    The layer 4 load balancing virtual server configuration is completed.

Troubleshooting

September 14, 2021

If the load balancing does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Resources for Troubleshooting Load Balancing

For best results, use the following resources to troubleshoot a content switching issue on a Citrix ADC appliance:

- Latest ns.conf file
- Relevant `newnslog` files
- Ethereal packet traces recorded on the appliance and relevant client, if possible
- The ns.log file

In addition to the above resources, the following tools expedite troubleshooting:

- A browser add-on tool that can display HTTP headers. This can be used to troubleshoot persistency related issues.
- The Wireshark application customized for the Citrix ADC trace files.

Troubleshooting Load Balancing Issues

- **Issue**

CPU usage reaches 100% when a user monitor is bound to a service that is bound to a virtual server on which the -m MAC option is enabled.

- **Resolution**

Bind a non-user monitor to the service.

- **Issue**

  I created a user script for monitoring, but it is not working.

  Resolution

  Check the number of arguments in the script. The limit is 512. A script with more than 512 arguments might not work properly. Use the nsumon-debug.pl script from the CLI to debug the script.

- **Issue**

  I see a lot of monitor probes, and they seem to be increasing the network traffic unnecessarily. Is there a way to off the monitor probes?

  Resolution

  You can set off the monitor probe connections, by disabling the monitor or setting the value of the healthMonitor parameter in the set service command to NO. With the NO option, the appliance shows the service as UP at all times.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Issue**

  I have set up monitors for services, but connections are still directed to servers that are DOWN.

  Resolution

  You probably need to decrease the monitor probe intervals. The Citrix ADC appliance does not detect the DOWN state until the monitor sends a probe.

- **Issue**

  A metric bound to the monitor is present in the local and custom metric tables.

  Resolution

  Add the local prefix to the metric name if the metric is chosen from the local metric table. However, if the metric is chosen from the custom table, you don't need to add any prefix.

- **Issue**

  The monitor probes to a service are not reaching the service.

  Resolution

  Check whether you have set a limit on the number of connections for a service. If yes, exempt monitor-probe connections from this limit by setting the monitorSkipMaxClient parameter to ENABLED.

- **Issue**

  I am able to ping the servers, but the state of the services is always shown as DOWN.

  Resolution

  Check the type of monitors configured. For example, if a server is not configured for SSL and you use an HTTPS monitor, the state of the service is marked as DOWN. In this case using a TCP monitor must change the state of the service to UP.

- **Issue**

  Setting a weight for load monitors does not help in deciding the state of the service.

  Resolution

  Load monitors cannot decide the state of the service. Therefore, setting a weight on the load monitors is inappropriate.

- **Issue**

  A service is not stable.

  Resolution

  Consider troubleshooting the following components:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Verify that a correct server is bound to the service.
- Verify the type of monitor bound to the service.
- Verify the reasons for the monitor failures. You can open a service from the Services page and verify the details for the number of probes, failures, and last response status for the monitor in the Monitors tab of the Configure service dialog box. To display the details, click the monitor configured.
- If it is a custom monitor, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
- You can record packet traces on the Citrix ADC appliance and verify the monitor probes and server response for further investigation.

- **Issue**

  The virtual IP (VIP) address is not stable or its status is displayed as DOWN.

  Resolution

  Consider troubleshooting the following components:

  - Verify that the load balancing feature is licensed.
  - Verify that the feature is enabled.
  - Verify that an appropriate service is bound to the virtual server.
  - If the status of the VIP address is displayed as DOWN, verify that an administrator has enabled the service. If it is not, the status of the service must be Out-Of-Service. In such a case, you must enable the service and verify if the issue is resolved.
  - Verify the service(s) bound to the virtual server and complete the troubleshooting steps mentioned for service not stable issue.
  - If the VIP address is not stable, all the services bound to the virtual server must fail. Therefore, verify if all the services are failing at the same time. If it is so, there is a network issue between the Citrix ADC appliance and the servers.

- **Issue**

  The site is experiencing uneven load balancing.

  Resolution

  Consider troubleshooting the following components:

  - Verify the load balancing method configured on the appliance.
  - Verify weights associated with the services are as expected.
  - If the load balancing method is other than round robin, verify the number of connections to the server logged in the `newnslog` file. You can run the following command to verify the number on the `newnslog` file:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
# nsconmsg –K <newnslog_file> -s ConLb=2 –d oldconmsg
```

Verify the services for the specific virtual server and check for the Response time, Open Established connections (OE), number of requests, Persistent requests and persistent rate (P) to troubleshoot the issue further.

- If the load balancing method is round robin, verify the persistent requests as mentioned in the preceding step. Additionally, verify if the service is not stable. If it is not, complete the troubleshooting steps mentioned for service not stable issue
- Verify if persistency is configured on the appliance.
- Verify if any service is not stable. If yes, complete the troubleshooting steps mentioned for service not stable issue.

- **Issue**

  The service status is displayed as DOWN.

  Resolution

  Consider troubleshooting the following components:

  - Verify whether a SNIP address is configured.
  - Verify that appropriate monitors are bound to the service.
  - If custom monitors are bound to the service, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
  - Verify if the status of service is displayed as DOWN for the server that is in another subnet. If yes, verify if Use Subnet IP (USNIP) resolves the issue because this can be due to the MIP address being unable to communicate to the server.

- **Issue**

  There is an issue with the response time.

  Resolution

  Consider troubleshooting the following components:

  - Verify the server response time from the service stats either by running the following command:

    ```
    # nsconmsg –K <newnslog_file> -s ConLb=2 –d oldconmsg
    ```

  - Check for service not stable and service status being displayed as DOWN issues.

- **Issue**

  One of the servers is serving more requests than the other load balanced servers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Resolution

Consider troubleshooting the following components:

- Verify the load balancing method. Use the round robin method to distribute the client request equally regardless of the load on the servers.
- Determine whether persistence is enabled for the load balancing configuration. If persistence is enabled, a given server might be carrying a heavier load to maintain its session, especially If the persistence sessions are long.
- Verify whether weights are assigned to each service. Assigning proper weights helps in proper load distribution.

- **Issue**

  Connections to a specific load balanced server are stalled. For example, all connections to one Outlook server might be stalled.

  Resolution

  Consider troubleshooting the following components:

  - Verify the load balance method. If it is round robin, consider changing the method to least connections.
  - Consider reducing the monitor time-out period. A shorter timeout period helps in marking a service as DOWN sooner, which would help in directing the traffic to the server which is functional.
  - If the connections are stalled for a long period, a surge queue might build. Consider flushing the surge queue to avoid a sudden spike in load on the server.
  - If the servers are working at their maximum level, consider adding a new server for better performance.

- **Issue**

  A majority of the connections are directed to a particular server, even when the least connections method for load balancing is configured.

  Resolution

  Determine whether persistence is configured and is of type source IP. If source IP persistence is configured even with the least connections method, the requests go to a specific server. The server's IP address is required for maintaining the session information. Consider using HTTP Cookies based persistence.

- **Troubleshooting Tips**
  For other issues, consider the following tips to troubleshoot an issue not listed above:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- If multiple load monitors are bound to a service, the load on the service is the sum of all the values on the load monitors bound to it. For load balancing to work properly, you must bind the same set of monitors to all the services.
- If you disable a load monitor bound to the service and the service is bound to a virtual server, the virtual server uses the round robin method for load balancing.
- When you bind a service to a virtual server where the load balancing method is CUSTOMLOAD and the service status is UP, the virtual server uses the initial round robin method for load balancing. It continues to be in round robin if the service has no custom load monitors, or if the status of at least one of the custom load monitors is not UP.
- All the services that are bound to a virtual server where the load balancing method is CUSTOMLOAD, the services must have load monitors bound to them.
- The CUSTOMLOAD load balancing method also follows the startup round robin.
- If you disable a metric-based binding and this is the last active metric, the specific virtual server uses the round robin method for load balancing. A metric is disabled by setting the metric threshold to zero.
- When a metric bound to a monitor crosses the threshold value, that particular service is not considered for load balancing. If all the services have reached the threshold, the virtual server uses the round robin method for load balancing and an error message "5xx - server busy error"is displayed.
- A maximum of 10 metrics from a custom table can be bound to the monitor.
- The OIDs must be scalar variables.
- For successful load balancing, the interval must be as low as possible. If the interval is high, the time period for retrieving the load value increases. As a result, load balancing takes place using improper values.
- A user cannot modify the local table.

Load balancing FAQs

September 14, 2021

What are the various load balancing policies I can create on the Citrix ADC appliance

You can create the following types of load balancing policies on the Citrix ADC appliance:

- Least Connections
- Round Robin
- Least response time
- Least bandwidth

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Least packets
- URL hashing
- Domain name hashing
- Source IP address hashing
- Destination IP address hashing
- Source IP - Destination IP hashing
- Token
- LRTM

Can I achieve the Web farm security by implementing load balancing using the Citrix ADC appliance?

Yes. You can achieve Web farm security by implementing load balancing using the Citrix ADC appliance. Citrix ADC appliance enables you to implement the following options of the load balancing feature:

- IP Address hiding: Enables you to install the actual servers to be on private IP address space for security reasons and for IP address conservation. This process is transparent to the end-user because the Citrix ADC appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the private subnet, such as FTP or a Telnet server, through a different VIP on the appliance for that service.
- Port Mapping: Enables the actual TCP services to be hosted on non-standard ports for security reasons. This process is transparent to the end-user as the Citrix ADC appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

What are the various devices that I can use to load balance with a Citrix ADC appliance?

You can load balance the following devices with a Citrix ADC appliance:

- Server farms
- Caches or Reverse Proxies
- Firewall devices
- Intrusion detection systems
- SSL offload devices
- Compression devices
- Content Inspection servers

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Why do I implement the load balancing feature for the website?

You can implement the Load balancing feature for the website to take the following advantages:

- Reduce the response time: When you implement the load balancing feature for the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.
- Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, if the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors do not even notice any downtime. Any load balancing solution immediately stops sending traffic to the back-end server that is not available.

Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?

- If you enable the MBF option, the Citrix ADC appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires the best path to be chosen for the return traffic.
- Enabling the MBF option breaks this topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

Networking

September 14, 2021

The following topics provide a conceptual reference and instructions for configuring the various networking components on the Citrix ADC appliance.

IP Addressing	Learn the various types of Citrix ADC owned IP addresses and how to create, customize, and remove them.
Interfaces	Configure some of the basic network configurations that must be done to get started.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Access Control Lists (ACLs)	Configure the different types of Access Control Lists and how to create, customize, and remove them.
IP Routing	Learn and configure the routing functionality of the Citrix ADC appliance, both static and dynamic.
Internet Protocol version 6 (IPv6)	Learn how the Citrix ADC appliance supports IPv6.
Traffic Domains	Learn and configure traffic domains to segment network traffic for different applications.
VXLAN	Learn and configure VXLANs to meet the scalability needs in your datacenter.

IP Addressing

September 14, 2021

Before you can configure the Citrix ADC appliance, you must assign the NSIP address, also known as the Management IP address. You can also create other Citrix ADC-owned IP addresses for abstracting servers and establishing connections with the servers. In this type of configuration, the appliance serves as a proxy for the abstracted servers. You can also proxy connections by using network address translations (INAT and RNAT). When proxying connections, the appliance can behave either as a bridging (Layer 2) device or as a packet forwarding (Layer 3) device. To make packet forwarding more efficient, you can configure static ARP entries. For IPv6, you can configure neighbor discovery (ND).

Configuring Citrix ADC-owned IP addresses

September 14, 2021

The Citrix ADC-owned IP addresses—NSIP address, Virtual IP Addresses (VIPs), Subnet IP Addresses (SNIPs), and Global Server Load Balancing Site IP Addresses (GSLBIPs)—exist only on the Citrix ADC appliance. The NSIP uniquely identifies the Citrix ADC on your network, and it provides access to the appliance. A VIP is a public IP address to which a client sends requests. The Citrix ADC terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

SNIP or a MIP as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique GSLBIP. You can configure some Citrix ADC-owned IP addresses to provide access for management applications.

Configuring the NSIP address

September 14, 2021

The NSIP address is the IP address at which you access the Citrix ADC appliance for management purposes. The appliance can have only one NSIP, which is also called the management IP address. You must add this IP address when you configure the Citrix ADC for the first time. You cannot remove an NSIP address. For security reasons, the NSIP should be a non-routable IP address on your organization's LAN.

If you modify this address, you must reboot the Citrix ADC appliance. If the subnet address of the new NSIP address is different from the previous one, you must add a default route for this subnet so that the new NSIP address becomes reachable from other networks on the LAN.

> **Important**
>
> Configuring the NSIP address is mandatory.

Changing the NSIP address of a Citrix ADC appliance consists of the following tasks:

- Change the NSIP address.
- Add a default route for the subnet address of the NSIP address, if one is not present.
- Save the configuration.
- Restart the appliance.

Command Line Procedures

To change the NSIP address by using the CLI:

At the command prompt, type:

- **set ns config -IPAddress** <ip_addr> **-netmask** <netmask>
- **show ns config**

To add a default route by using the CLI:

At the command prompt, type:

- **add route 0 0** <gateway IP address>

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **show route**

To save the configuration by using the CLI:

At the command prompt, type:

- **save config**

To restart the Citrix ADC appliance by using the CLI:

At the command prompt, type:

- **reboot**

GUI Procedures

To configure the NSIP address by using the GUI:

1. Click the gear icon in the top-right corner of the **Configuration** page.
2. Click the **NSIP address** pane.
3. On the **NSIP address** page, set the following parameters, and then click **Done**:
    - NSIP address
    - Netmask

To add a default route by using the GUI:

Navigate to **System** > **Network** > **Routes** and, on the **Basic** tab, add a default route with the following parameter settings, and then click **Create**.

- Network (set to zero)
- Netmask (set to zero)
- Gateway (IP address of the gateway)

To restart the Citrix ADC by using the GUI:

1. On the **System Information** tab page of the **System** node, click **Reboot**.
2. When prompted to reboot, select **Save Configuration** to make sure that you do not lose any configurations.

Sample configuration

In the following example, the NSIP address of a Citrix ADC appliance is changed to 192.0.2.90, which has a different subnet address (192.0.2.0/24) than the previous NSIP address. Therefore, a default route is added for this subnet, so that the new NSIP address becomes reachable from other networks.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> set nsconfig -ipAddress 192.0.2.90 -netmask 255.255.255.0

 Warning: The configuration must be saved and the system rebooted for
    these settings to take effect
> add route 0 0 192.0.2.1

 Warning: The configuration must be saved and the system rebooted for
    these settings to take effect
> save config

 Done
> reboot
```

Configuring and Managing Virtual IP (VIP) Addresses

September 14, 2021

Configuration of a virtual server IP (VIP) address is not mandatory during initial configuration of the Citrix ADC. When you configure load balancing, you assign VIP addresses to virtual servers.

For more information about configuring a load balancing setup, see Load Balancing.

In some situations, you need to customize VIP attributes or enable or disable a VIP address. A VIP address is usually associated with a virtual server, and some of the VIP attributes are customized to meet the requirements of the virtual server. You can host the same virtual server on multiple Citrix ADC appliances residing on the same broadcast domain, by using ARP and ICMP attributes. After you add a VIP (or any IP address), the appliance sends, and then responds to, ARP requests. VIPs are the only Citrix ADC-owned IP addresses that can be disabled. When a VIP address is disabled, the virtual server using it goes down and does not respond to ARP, ICMP, or L4 service requests. As an alternative to creating VIP addresses one at a time, you can specify a consecutive range of VIP addresses.

To create a VIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example:

```
> add ns ip 10.102.29.59 255.255.255.0 -type VIP
 Done
```

To create a range of VIP addresses by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example:

```
> add ns ip 10.102.29.[60-64] 255.255.255.0 -type VIP
ip "10.102.29.60" added
ip "10.102.29.61" added
ip "10.102.29.62" added
ip "10.102.29.63" added
ip "10.102.29.64" added
 Done
```

To enable or disable an IPv4 VIP address by using the CLI:

At the command prompt, type one of the following sets of commands to enable or disable a VIP and verify the configuration:

- enable ns ip <IPAddress>
- show ns ip <IPAddress>
- disable ns ip <IPAddress>
- show ns ip <IPAddress>

Example:

```
> enable ns ip 10.102.29.79
 Done
> show ns ip 10.102.29.79

        IP: 10.102.29.79
        Netmask: 255.255.255.255
        Type: VIP
        state: Enabled
        arp: Enabled
        icmp: Enabled
        vserver: Enabled
        management access: Disabled
          telnet: Disabled
          ftp: Disabled
          ssh: Disabled
          gui: Disabled
          snmp: Disabled
        Restrict access: Disabled
        dynamic routing: Disabled
        hostroute: Disabled
 Done
> disable ns ip 10.102.29.79
 Done
> show ns ip 10.102.29.79

        IP: 10.102.29.79
        Netmask: 255.255.255.255
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
28          Type: VIP
29          state: Disabled
30          arp: Enabled
31          icmp: Enabled
32          vserver: Enabled
33          management access: Disabled
34            telnet: Disabled
35            ftp: Disabled
36            ssh: Disabled
37            gui: Disabled
38            snmp: Disabled
39          Restrict access: Disabled
40          dynamic routing: Disabled
41          hostroute: Disabled
42
43   Done
```

To configure a VIP address by using the GUI:

Navigate to **System** > **Network** > **IPs** > **IPV4s**, and add a new IP address or edit an existing address.

To create a range of VIP addresses by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. In the **Action** list, select **Add Range**.

To enable or disable a VIP address by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Do one of the following:
   - Select a VIP address.
   - Hold down the **Ctrl** key and select multiple server address entries.
   - Hold down the **Shift** key and select a range of server address entries.
   - Select all the addresses by selecting the checkbox on the left side of the header row.
3. From the **Action** list, select **Disable** or **Enable**.

Detecting a Citrix ADC Appliance in a UDP Load Balancing Setup through TTL Updates

The following table displays how a Citrix ADC appliance handles the TTL value of received packets in different functionalities.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Functionality	TTL value
Virtual Server	TTL is set to 255 when forwarding the request to the backend servers. TTL is decremented by 1 when forwarding the response to the client.
L2 Mode	TTL is not changed.
L3 Mode	TTL is set to 255.
INAT	TTL is set to 255 when forwarding the request to the backend server. TTL is decremented by 1 when forwarding the response to the client.

Some enterprises/scenarios running a monitoring application requires the Citrix ADC appliance of a load balancing setup to be detected as one of the hop in a traceroute. A Citrix ADC appliance of a load balancing setup is not detected in a traceroute because the appliance, by default, sets the TTL value to 255 instead of decrementing it when forwarding the request to a backend server.

To meet this requirement, **Decrement TTL** parameter of a VIP address can be used. This parameter applies to all UDP virtual servers using this VIP.

When you enable the **Decrement TTL** parameter of a VIP, the Citrix ADC appliance decrements the TTL value by 1 instead of setting it to 255 when forwarding requests, which are received on the UDP virtual servers that uses this VIP.

Monitoring applications using traceroute data can now detect the presence of a Citrix ADC appliance of a UDP load balancing setup.

Before You Begin

Before you begin configuring a Citrix ADC appliance to be detected in a traceroute of a load balancing setup, note the following points:

- Decrement TTL parameter is supported only for UDP load balancing virtual servers.
- Decrement TTL parameter is supported for IPv4 VIP as well as IPv6 VIP (VIP6) addresses.
- Decrement TTL parameter is supported for standalone Citrix ADC appliances as well as for high availability (HA) and cluster setups.

Configuration Steps

Configuring a Citrix ADC appliance to be detected in a traceroute of a UDP load balancing setup consists of the following tasks:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Create a UDP load balancing configuration
- Enable the Decrement TTL parameter for the VIP address

CLI Procedures

To enable the decrement TTL option for a VIP address by using the CLI:

- To enable the decrement TTL option for a VIP address while adding the VIP address, at the command prompt, type:
  - **add ns ip** <ip> <mask> -**type VIP** -**decrementTTL ENABLED**
  - **show ns ip** <VIP address>
- To enable the decrement TTL option for an existing VIP address, at the command prompt, type:
  - **set ns ip** <ip> <mask> -**decrementTTL ENABLED**
  - **show ns ip** <VIP address>

To enable the decrement TTL option for a VIP6 address by using the CLI:

- To enable the decrement TTL option for a VIP6 address while adding the VIP6 address, at the command prompt, type:
  - **add ns ip6** <IP6/prefix> <mask> -**type VIP** -**decrementTTL ENABLED**
  - **show ns ip6** <VIP6/prefix>
- To enable the decrement TTL option for an existing VIP6 address, at the command prompt, type:
  - **set ns ip6** <ip6/prefix> <mask> -**decrementTTL ENABLED**
  - **show ns ip6** <VIP6 address>

```
1    > add ns ip 203.0.113.30 -type VIP -decrementTTL ENABLED
2     Done
3
4    > add ns ip6  2001:DB8:5001::30 -type VIP -decrementTTL ENABLED
5     Done
```

GUI Procedures

To enable the decrement TTL option for a VIP address by using the GUI:

Navigate to **System** > **Network** > **IPs** > **IPv4s**, and enable the **Decrement TTL** parameter while adding a new VIP address or editing an existing address.

To enable the decrement TTL option for a VIP6 address by using the GUI:

Navigate to **System** > **Network** > **IPs** > **IPv6s**, and enable the **Decrement TTL** parameter while adding a new VIP6 address or editing an existing address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring ARP response Suppression for Virtual IP addresses (VIPs)

September 14, 2021

You can configure the Citrix ADC appliance to respond or not respond to ARP requests for a Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

For example, if virtual servers V1, of type HTTP, and V2, of type HTTPs, share VIP address 10.102.29.45 on a Citrix ADC appliance, you can configure the appliance to not respond to any ARP request for VIP 10.102.29.45 if both V1 and V2 are in the DOWN state.

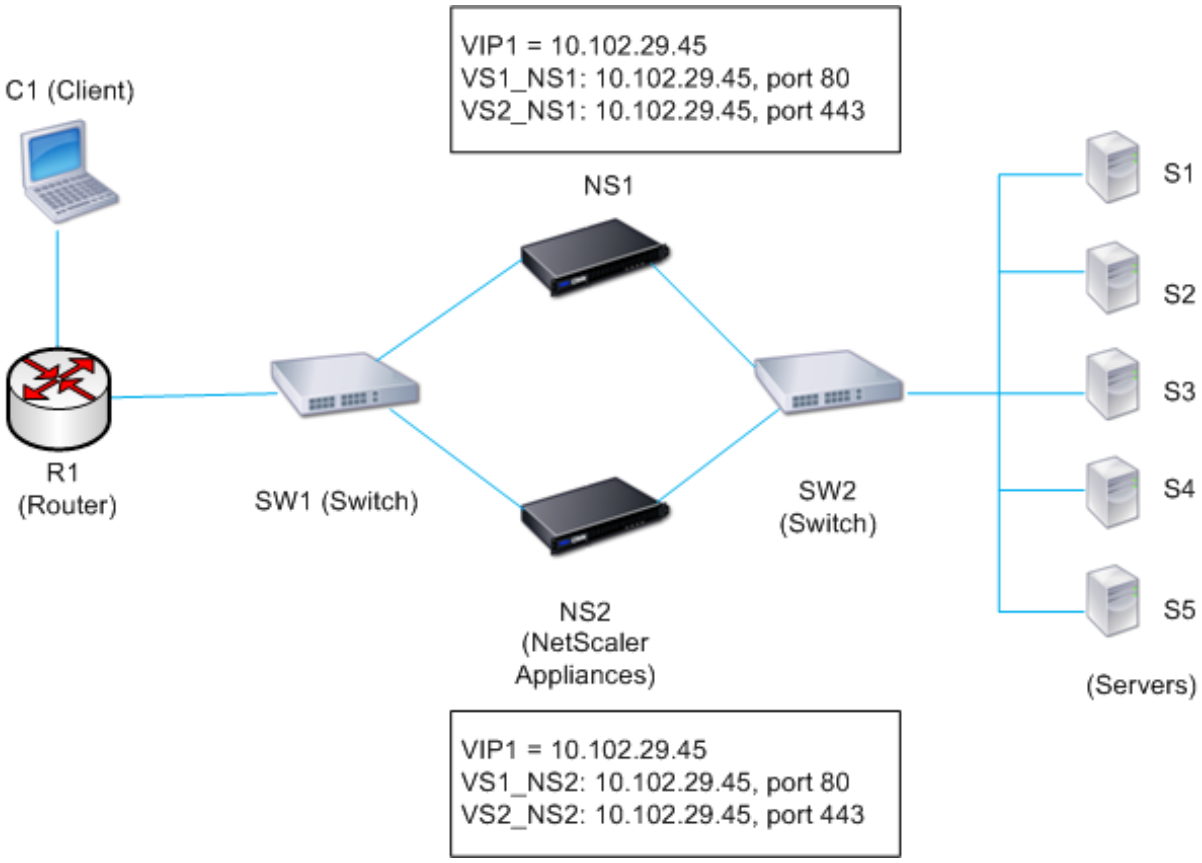
The following three options are available for configuring ARP-response suppression for a virtual IP address.

- **NONE**. The Citrix ADC appliance responds to any ARP request for the VIP address, irrespective of the state of the virtual servers associated with the address.
- **ONE VSERVER**. The Citrix ADC appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.
- **ALL VSERVER**. The Citrix ADC appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Following table shows the sample behavior of Citrix ADC appliance for a VIP configured with two virtual servers:

Associated virtual servers for a VIP	STATE 1	STATE 2	STATE 3	STATE 4
NONE				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	Yes
ONE VSERVER				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	No
ALL VSERVER				

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



Associated virtual servers for a VIP	STATE 1	STATE 2	STATE 3	STATE 4
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	No	No	No

Consider an example where you want to test the performance of two virtual servers, V1 and V2, which have the same VIP address but are of different types and are each configured on Citrix ADC appliances NS1 and NS2. Let's call the shared VIP address *VIP1*.

V1 load balances servers S1, S2, and S3. V2 load balances servers S4 and S5.

On both NS1 and NS2, for VIP1, the ARP suppression parameter is set to ALL_VSERVER. If you want to test the performance of V1 and V2 on NS1, you must manually disable V1 and V2 on NS2, so that NS2 does not respond to any ARP request for VIP1.

Figure 1.

The execution flow is as follows:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Client C1 sends a request to V1. The request reaches R1.
2. R1 does not have an APR entry for the IP address (VIP1) of V1, so R1 broadcasts an ARP request for VIP1.
3. NS1 replies with source MAC address MAC1 and source IP address VIP1. NS2 does not reply to the ARP request.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table, and R1 updates the ARP entry with MAC1 and VIP1.
5. R1 forwards the packet to address VIP1 on NS1.
6. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP addresses and S2. When S2 sends a response to the client, the response returns by the same path.
7. Now you want to test the performance of V1 and V2 on NS2, so you enable V1 and V2 on NS2 and disable them on NS1. NS2 now broadcasts an ARP message for VIP1. In the message, MAC2 is the source MAC address and VIP1 is the source IP address.
8. SW1 learns the port number for reaching MAC2 from the ARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS2. R1 updates its ARP table.
9. Now suppose the ARP entry for VIP1 times out in the ARP table of R1, and client C1 sends a request for V1. Because R1 does not have an APR entry for VIP1, it broadcasts an ARP request for VIP1.
10. NS2 replies with a source MAC address and VIP1 as the source IP address. NS1 does not reply to the ARP request.

To configure ARP response suppression by using the CLI:

At the command prompt, type:

- **set ns ip** -**arpResponse** <arpResponse>]
- **sh ns ip** <IPAddress>

Example:

```
1 > set ns ip 10.102.29.96 -arpResponse ALL_VSERVERS
2  Done
```

To configure ARP response suppression by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Open an IP address entry and select the type of ARP Response.

Configuring Subnet IP Addresses (SNIPs)

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

A subnet IP address (SNIP) is a Citrix ADC owned IP address that is used by the Citrix ADC to communicate with the servers.

The Citrix ADC uses the subnet IP address as a source IP address to proxy client connections to servers. It also uses the subnet IP address when generating its own packets, such as packets related to dynamic routing protocols, or to send monitor probes to check the health of the servers. Depending on your network topology, you might have to configure one or more SNIPs for different scenarios.

To configure a SNIP address on a Citrix ADC, you add the SNIP address and then enable global Use Subnet IP (USNIP) mode. As an alternative to creating SNIPs one at a time, you can specify a consecutive range of SNIPs.

To configure a SNIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example:

```
1 > add ns ip 10.102.29.203 255.255.255.0 -type SNIP
2  Done
```

To create a range of SNIP addresses by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example:

```
1 > add ns ip 10.102.29.[205-209] 255.255.255.0 -type SNIP
2 ip "10.102.29.205" added
3 ip "10.102.29.206" added
4 ip "10.102.29.207" added
5 ip "10.102.29.208" added
6 ip "10.102.29.209" added
7  Done
```

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

- enable ns modeUSNIP
- disable ns modeUSNIP

To configure a SNIP address by using the GUI:

Navigate to System > Network > IPs > IPV4s, and add a new SNIP address or edit an existing address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To create a range of SNIP addresses by using the GUI:

1. Navigate to System > Network > IPs > IPV4s.
2. In the Action list, select Add Range.

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

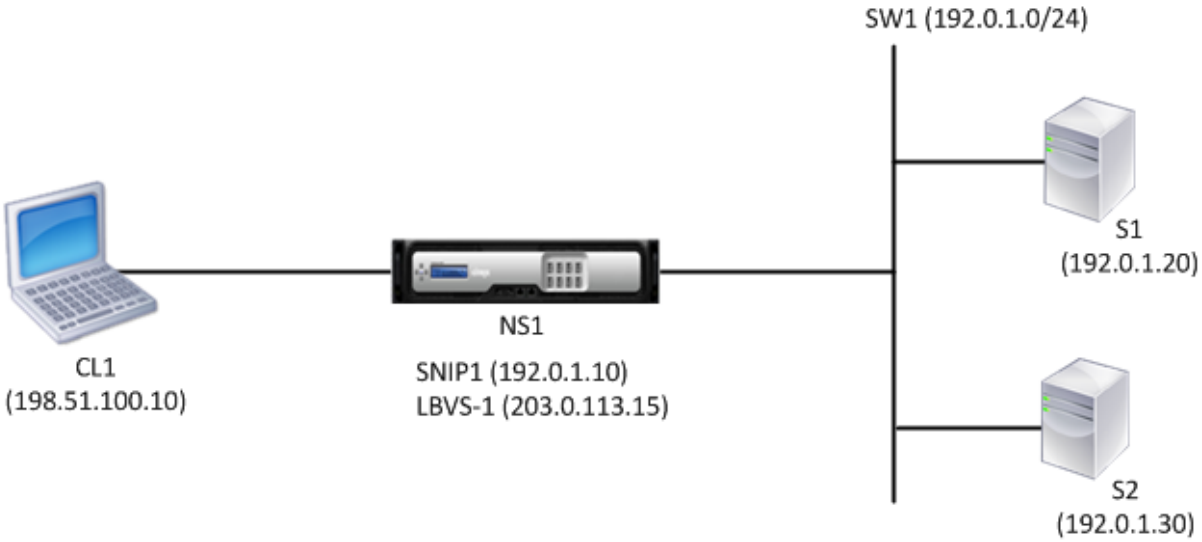
- enable ns mode USNIP
- disable ns mode USNIP

To enable or disable USNIP mode by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Subnet IP option.

Using SNIPs for a Directly Connected Server Subnet

To enable communication between the Citrix ADC and a server that is either connected directly to the Citrix ADC or connected through only an L2 switch, you must configure a subnet IP address that belongs to the subnet of the server. You must configure at least one subnet IP address for each directly connected subnet, except for the directly connected management subnet that is connected through NSIP.



Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to the same subnet.

SNIP address SNIP1, which belongs to the same subnet as S1 and S2, is configured on NS1. As soon as SNIP1 is configured, NS1 broadcasts ARP packets for SNIP1.

Services SVC-S1 and SVC-S2 on NS1 represent S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for S1 and S2 to resolve IP-to-MAC mapping. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about configuring load balancing on a Citrix ADC, see Load Balancing.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP1 and S2.
5. NS1 sends the request packet to S2 from SNIP1. The request packet has:
   - Source IP = SNIP1 (192.0.1.10)
   - Destination IP = IP address of S2 (192.0.1.30)
6. S2's response returns by the same path.

Using SNIPs for Server Subnets Connected through a Router

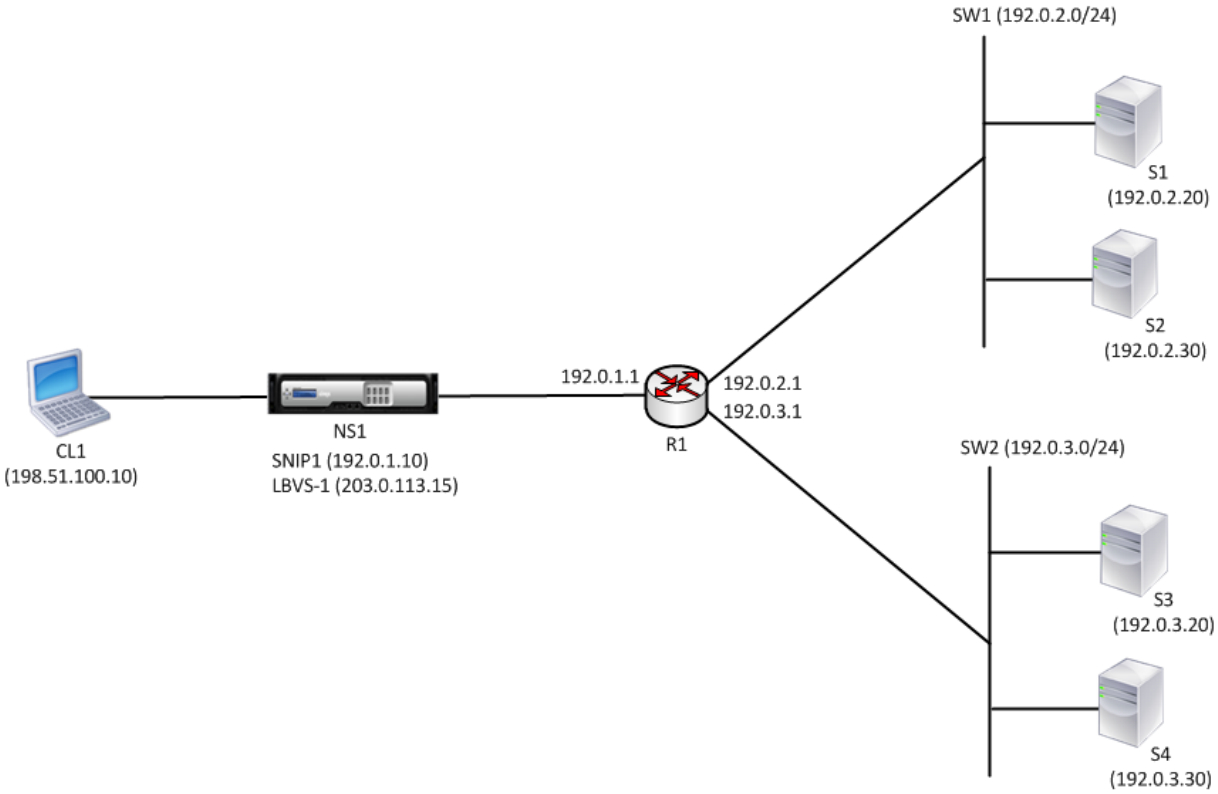
To enable communication between the Citrix ADC and servers in subnets connected through a router, you must configure at least one subnet IP address that belongs to the subnet of the directly connected interface to the router. The ADC uses this subnet IP address to communicate with servers in subnets that can be reached through the router.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1, S2, S3, and S4, which are connected to NS1 through router R1.

S1 and S2 belong to same subnet, 192.0.2.0/24, and are connected to R1 through L2 switch SW1. S3 and S4 belong to a different subnet, 192.0.3.0/24, and are connected to R1 through L2 switch SW2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Citrix ADC NS1 is connected to router R1 through subnet 192.0.1.0/24. SNIP address SNIP1, which belongs to the same subnet as the directly connected interface to the router (192.0.1.0/24), is configured on NS1. NS1 uses this address to communicate with servers S1 and S2, and with servers S3 and S4.



For more information about configuring load balancing on a Citrix ADC, see Load Balancing.

As soon as address SNIP1 is configured, NS1 broadcasts ARP announcement packets for SNIP1.

NS1's routing table consists of route entries for S1, S2, S3, and S4 through R1. These route entries are either static route entries or advertised by R1 to NS1, using dynamic routing protocols.

Services SVC-S1, SVC-S2, SVC-S3, and SVC-S4 on NS1 represent servers S1, S2, S3, and S4. NS1 finds, in its routing tables, that these servers are reachable through R1. NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about IP routing on a Citrix ADC, see IP Routing.

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S3.

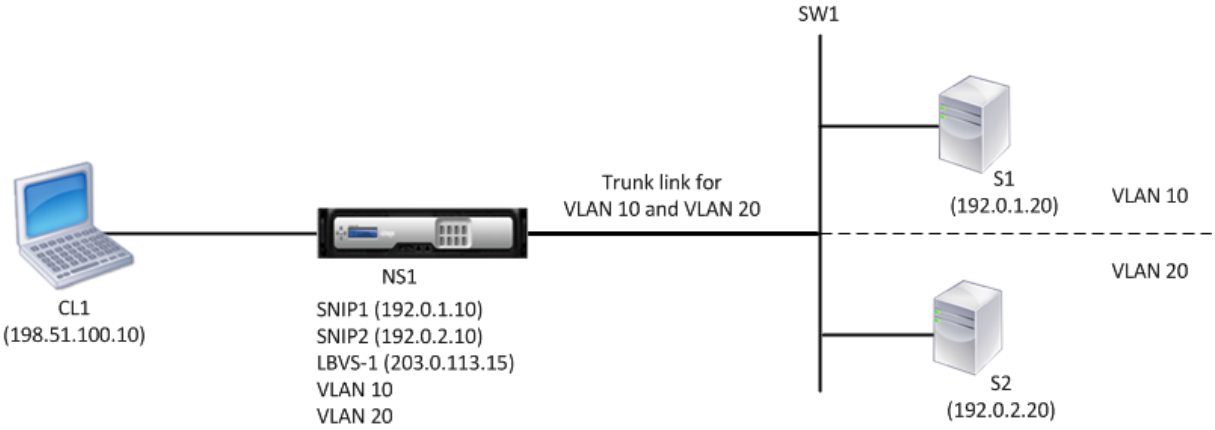
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. NS1 checks its routing table and finds that S3 is reachable through R1. SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as router R1, NS1 opens a connection between SNIP1 and S3 through R1.
5. NS1 sends the request packet to R1 from SNIP1. The request packet has:
   - Source IP address = SNIP1 (192.0.1.10)
   - Destination IP address = IP address of S3 (192.0.3.20)
6. The request reaches R1, which checks its routing table and forwards the request packet to S3.
7. S3's response returns by the same path.

Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

When you have multiple server subnets (VLANs) on an L2 switch that is connected to a Citrix ADC, you must configure at least one SNIP address for each of the server subnets, so that the Citrix ADC can communicate with these server subnets.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to different subnets and are part of VLAN 10 and VLAN20, respectively. The link between NS1 and SW1 is a trunk link and is shared by VLAN10 and VLAN20.



For more information about configuring load balancing on a Citrix ADC, see Load Balancing.

Subnet IP addresses SNIP1 (for reference purposes only) and SNIP2 (for reference purposes only) are configured on NS1. NS1 uses SNIP1 (on VLAN 10) to communicate with server S1, and SNIP2 (on VLAN 20) to communicate with S2. As soon as SNIP1 and SNIP2 are configured, NS1 broadcasts ARP announcement packets for SNIP1 and SNIP2.

For more information about configuring VLANs on a Citrix ADC, see Configuring a VLAN.

Services SVC-S1 and SVC-S2 on NS1 represent servers S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for them. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals to check their health. NS1 sends monitoring probes to S1 from address SNIP1, and to S2 from address SNIP2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP2 (192.0.2.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP2 and S2.
   Note: If S1 is selected, NS1 opens a connection between SNIP1 and S1.
5. NS1 sends the request packet to S2 from SNIP2. The request packet has:
   - Source IP = SNIP1 (192.0.2.10)
   - Destination IP = IP address of S2 (192.0.2.20)
6. S2's response returns by the same path.

Configuring GSLB Site IP Addresses (GSLBIP)

September 14, 2021

A GSLB site IP (GSLBIP) address is an IP address associated with a GSLB site. It is not mandatory to specify a GSLBIP address when you initially configure the Citrix ADC appliance. A GSLBIP address is used only when you create a GSLB site.

For more information about creating a GSLB site IP address, see Global Server Load Balancing.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Removing a Citrix ADC-owned IP address

September 14, 2021

You can remove any IP address except the NSIP. The following table provides information about the processes you must follow to remove the various types of IP addresses. Before removing a VIP, remove the associated virtual server.

IP address type	Implications
Subnet IP address (SNIP)	If IP address being removed is the last IP address in the subnet, the associated route is deleted from the route table. If the IP address being removed is the gateway in the corresponding route entry, the gateway for that subnet route is changed to another Citrix ADC-owned IP address.
Virtual Server IP address (VIP)	Before removing a VIP, you must first remove the virtual server associated with it. For information about removing the virtual server, see Load Balancing.
GSLB-Site-IP address	Before removing a GSLB site IP address, you must remove the site associated with it. For information about removing the site, see Global Server Load Balancing.

To remove an IP address by using the CLI:

At the command prompt, type:

rm ns ip <IPaddress>

Example:

```
1 > rm ns ip 10.102.29.54
2 Done
```

To remove an IP address by using the GUI:

Navigate to **System** > **Network** > **IPs** > **IPV4s**, delete the IP address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring Application Access Controls

September 14, 2021

Application access controls, also known as management access controls, form a unified mechanism for managing user authentication and implementing rules that determine user access to applications and data. You can configure SNIPs to provide access for management applications. Management access for the NSIP is enabled by default and cannot be disabled. You can, however, control it by using ACLs.

For information about using ACLs, see Access Control Lists (ACLs).

The Citrix ADC appliance does not support management access to VIPs.

The following table provides a summary of the interaction between management access and specific service settings for Telnet.

Management Access	Telnet (State Configured on the Citrix ADC)	Telnet (Effective State at the IP Level)
Enable	Enable	Enable
Enable	Disable	Disable
Disable	Enable	Disable
Disable	Disable	Disable

The following table provides an overview of the IP addresses used as source IP addresses in outbound traffic.

Application/ IP	NSIP	SNIP	VIP
ARP	Yes	Yes	No
Server side traffic	No	Yes	No
RNAT	No	Yes	Yes
ICMP PING	Yes	Yes	No
Dynamic routing	Yes	Yes	Yes

The following table provides an overview of the applications available on these IP addresses.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Application/ IP	NSIP	SNIP	VIP
SNMP	Yes	Yes	Yes
System access	Yes	Yes	No

You can access and manage the Citrix ADC by using applications such as Telnet, SSH, GUI, and FTP.

Note: Telnet and FTP are disabled on the Citrix ADC for security reasons. To enable them, contact the customer support. After the applications are enabled, you can apply the controls at the IP level.

To configure the Citrix ADC to respond to these applications, you need to enable the specific management applications. If you disable management access for an IP address, existing connections that use the IP address are not terminated, but no new connections can be initiated.

Also, the non-management applications running on the underlying FreeBSD operating system are open to protocol attacks, and these applications do not take advantage of the Citrix ADC appliance's attack prevention capabilities.

You can block access to these non-management applications on a SNIP or NSIP. When access is blocked, a user connecting to a Citrix ADC by using the SNIP or NSIP is not be able to access the non-management applications running on the underlying operating system.

To configure management access for an IP address by using the CLI:

At the command prompt, type:

set ns ip <IPAddress> -mgmtAccess <value> -**telnet** <value> -**ftp** <value> -**gui** <value> -**ssh** <value> -**snmp** <value> -**restrictAccess** (**ENABLED** | **DISABLED**)

Example:

```
> set ns ip 10.102.29.54 -mgmtAccess enabled -restrictAccess ENABLED
 Done
```

To enable management access for an IP address by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Open an IP address entry, and select the **Enable Management Access control** to support the listed applications option.

Enable secure access to Citrix ADC GUI using a subnet IP address(SNIP)

Secure access to Citrix ADC GUI is enabled by default for the Citrix ADC IP (NSIP). You can also enable secure access to the Citrix ADC appliance by using a subnet IP address of the appliance.

After configuring an SNIP address for secure access to a high availability pair, the secure access is available to the primary appliance, if you access the SNIP address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Citrix ADC CLI procedure

To enable secure access to Citrix ADC GUI using a subnet IP address(SNIP) by using the CLI:

At the command prompt, type:

set ns ip <SNIP_Address> **-type SNIP -gui SECUREONLY -mgmtAccess ENABLED**

Example:

```
> set ns ip 203.0.113.99 -mgmtAccess enabled -restrictAccess ENABLED

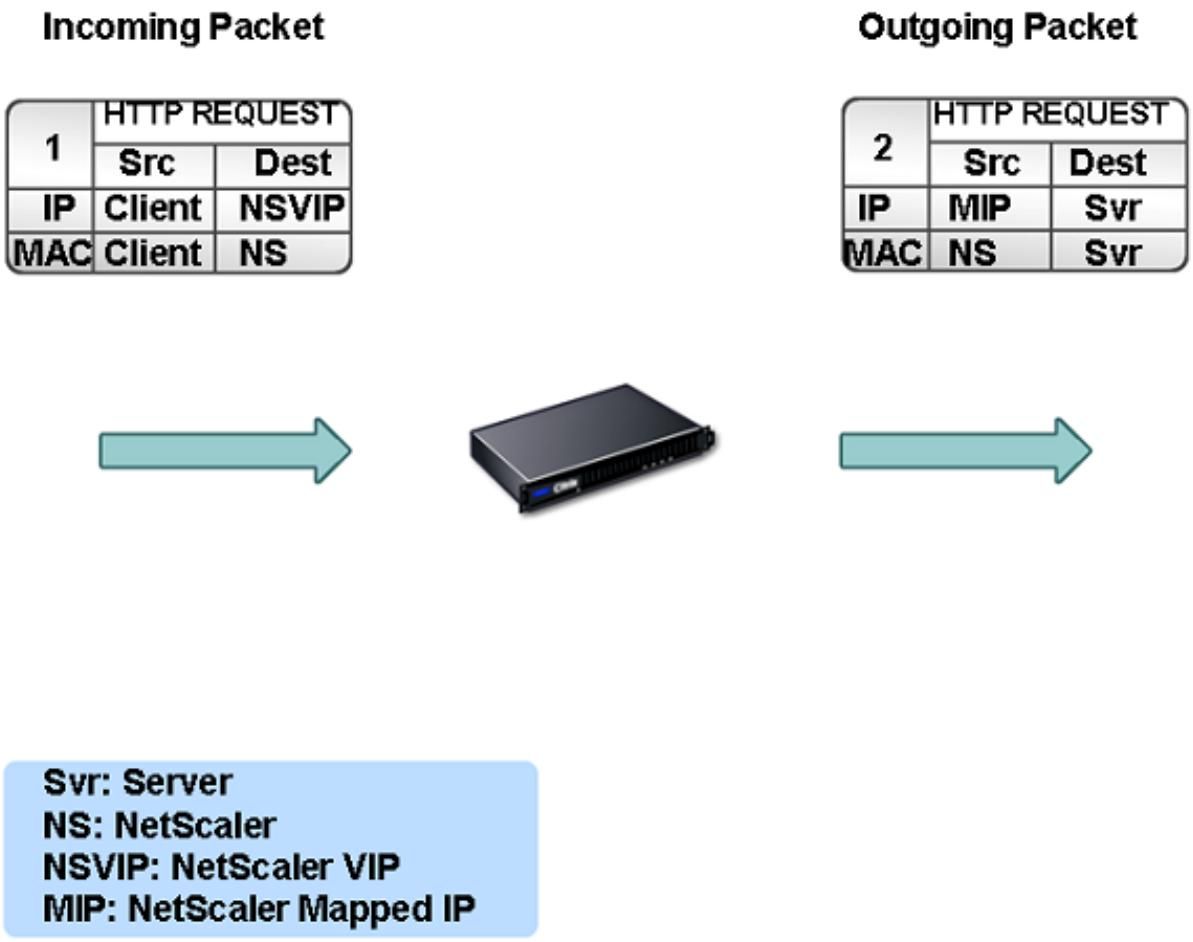
 Done
```

How the Citrix ADC Proxies Connections

September 14, 2021

When a client initiates a connection, the Citrix ADC appliance terminates the client connection, initiates a connection to an appropriate server, and sends the packet to the server. The appliance does not perform this action for service type UDP or ANY.

For more information about service types, see Load Balancing.



You can configure the Citrix ADC to process the packet before initiating the connection with a server. The default behavior is to change the source and destination IP addresses of a packet before sending the packet to the server. You can configure the Citrix ADC to retain the source IP address of the packets by enabling Use Source IP mode.

How the Destination IP Address Is Selected

Traffic sent to the Citrix ADC appliance can be sent to a virtual server or to a service. The appliance handles traffic to virtual servers and services differently. The Citrix ADC terminates traffic received at a virtual server IP (VIP) address and changes the destination IP address to the IP address of the server before forwarding the traffic to the server, as shown in the following diagram.

Figure 1. Proxying Connections to VIPs

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Packets destined for a service are sent directly to the appropriate server, and the Citrix ADC does not modify the destination IP addresses. In this case, the Citrix ADC functions as a proxy.

How the Source IP Address Is Selected

When the Citrix ADC appliance communicates with the physical servers or peer devices, by default, it does not use the IP address of the client. Citrix ADC maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address of a connection to the physical server. Depending on the subnet in which the physical server is placed, Citrix ADC selects a specific SNIP address.

Note: If the Use Source IP (USIP) option is enabled, appliance uses the IP address of the client.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Enable Use Source IP Mode

December 5, 2022

When the Citrix ADC appliance communicates with the physical servers or peer devices, by default, it uses one of its own IP addresses as the source IP. The appliance maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address for a connection to the physical server. The decision of selecting a SNIP address depends on the subnet in which the physical server resides.

If necessary, you can configure the Citrix ADC appliance to use the client's IP address as source IP. Some applications need the actual IP address of the client. The following use cases are a few examples:

- Client's IP address in the web access log is used for billing purposes or usage analysis.
- Client's IP address is used to determine the country of origin of the client or the originating ISP of the client. For example, many search engines such as Google provide content relevant to the location to which the user belongs.
- The application must know the client's IP address to verify that the request is from a trustworthy source.
- Sometimes, even though an application server does not need the client's IP address, a firewall placed between the application server and the Citrix ADC may need the client's IP address for filtering the traffic.

Enable Use Source IP mode (USIP) mode if you want the Citrix ADC to use the client's IP address for communication with the servers.

The following figure shows how the appliance uses IP addresses in USIP mode.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Before you begin

Before you enable USIP mode, note the following points:

- Enable USIP in the following situations:
  - Load balancing of Intrusion Detection System (IDS) servers
  - SMTP load balancing
  - Stateless connection failover
  - Sessionless load balancing
  - If you use the Direct Server Return (DSR) mode
- The USIP global setting applies only to services that are created after the USIP global setting is made. In other words, the USIP global setting does not apply to the existing services when the USIP global setting is made. For example, Disabling USIP globally does not disable USIP on the existing services. But it stops the subsequently created services from having USIP enabled automatically.

  To enable or disable USIP on a set of existing services, you need to enable or disable USIP on each of these services.
- When USIP is enabled, you must set server's gateway to one of the Citrix ADC owned IP addresses (of type Subnet IP (SNIP) so that server's response always go through the Citrix ADC appliance.
- If you enable USIP, set the idle timeout for server connections to a value lower than the default value, so that idle connections are cleared quickly on the server side.
- For transparent cache redirection, if you enable USIP, enable L2CONN also.
- Because HTTP connections are not reused when USIP is enabled, a large number of server-side connections may accumulate. Idle server connections can block connections for other clients. Therefore, set limits on maximum number of connections to a service. Citrix also recommends setting the HTTP server time-out value, for a service on which USIP is enabled, to a value lower than the default, so that idle connections are cleared quickly on the server side.
- As an alternative to USIP mode, you have the option of inserting the client's IP address (CIP) in the request header of the server-side connection for an application server that needs the client's IP address.
- In earlier Citrix ADC releases, USIP mode had the following source-port options for server-side connections:
  - **Use the client's port**. With this option, connections cannot be reused. For every request from the client, a new connection is made with the physical server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Use proxy port**. With this option, connection reuse is possible for all requests from the same client.

In the later Citrix ADC releases, if USIP is enabled, the default is to use a proxy port for server-side connections and not reuse connections. Not reusing connections may not affect the speed of establishing connections.

By default, the Use Proxy Port option is enabled if the USIP mode is enabled.

Note: If you enable the USIP mode, it is recommended to enable the Use Proxy Port option.

For more information about the Use Proxy Port option, see Configure the source port for server-side connections.

Configuration Steps

Enable Use Source IP mode (USIP) mode if you want Citrix ADC to use the client's IP address for communication with the servers. By default, USIP mode is disabled. USIP mode can be enabled globally on the Citrix ADC or on a specific service. If you enable it globally, USIP is enabled by default for all subsequently created services. If you enable USIP for a specific service, the client's IP address is used only for the traffic directed to that service.

CLI procedures

To globally enable or disable USIP mode by using the CLI:

At the command prompt, type one of the following commands:

- **enable ns mode USIP**
- **disable ns mode USIP**

To enable USIP mode for a service by using the CLI:

At the command prompt, type:

set service <name>@ -**usip** (**YES** | **NO**)

Example:

```
1 > set service Service-HTTP-1 -usip YES
2 Done
```

GUI procedures

To globally enable USIP mode by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Navigate to **System** > **Settings**, in **Modes and Features** group, click **Change Modes**.
2. Select the **Use Source IP** option.

To enable USIP mode for a service by using the GUI:

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**, and edit a service.
2. In **Advanced Settings**, select **Service Settings**, and select **Use Source IP Address**.

Configuring Network Address Translation

September 14, 2021

Network address translation (NAT) involves modification of the source and/or destination IP addresses and/or the TCP/UDP port numbers of IP packets that pass through the Citrix ADC appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your networks source IP addresses when data passes through the Citrix ADC. Also, with the help of NAT entries, your entire private network can be represented by a few shared public IP addresses. The Citrix ADC supports the following types of network address translation:

- **Inbound NAT (INAT).** The Citrix ADC replaces the destination IP address in the packets generated by the client with the private IP address of the server.
- **Reverse NAT (RNAT).** The Citrix ADC replaces the source IP address in the packets generated by the servers with the public NAT IP addresses.

Inbound Network Address Translation

December 14, 2024

When a client sends a packet to a Citrix ADC appliance that is configured for Inbound Network Address Translation (INAT), the appliance translates the packet's public destination IP address to a private destination IP address and forwards the packet to the server at that address.

The following configurations are supported:

- **IPv4-IPv4 Mapping**: A public IPv4 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv4 server. The Citrix ADC appliance translates the packet's public destination IP address to the destination IP address of the server. Then the appliance forwards the packet to the server at that address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **IPv4-IPv6 Mapping**: A public IPv4 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv6 server. The Citrix ADC appliance creates an IPv6 request packet with the IP address of the IPv6 server as the destination IP address.
- **IPv6-IPv4 Mapping**: A public IPv6 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv4 server. The Citrix ADC appliance creates an IPv4 request packet with the IP address of the IPv4 server as the destination IP address.
- **IPv6-IPv6 Mapping**: A public IPv6 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv6 server. The Citrix ADC appliance translates the packet's public destination IP address to the destination IP address of the server. Then the appliance forwards the packet to the server at that address.

When the appliance forwards a packet to a server, the source IP address assigned to the packet is determined as follows:

- If use subnet IP (USNIP) mode is enabled and use source IP (USIP) mode is disabled, the appliance uses a subnet IP address (SNIP) as the source IP address.
- If USIP mode is enabled, and USNIP mode is disabled the appliance uses the client IP (CIP) address as the source IP address.
- If both USIP and USNIP modes are enabled, USIP mode takes precedence.
- You can also configure the Citrix ADC to use a unique IP address as the source IP address, by setting the proxyIP parameter.
- If none of the above modes are enabled and a unique IP address has not been specified, the Citrix ADC attempts to use a MIP as the source IP address.
- If both USIP and USNIP modes are enabled and a unique IP address has been specified, the order of precedence is as follows: USIP-unique IP-USNIP-MIP-Error.

To protect the Citrix ADC from DoS attacks, you can enable a TCP proxy. However, if other protection mechanisms are used in your network, you can disable them.

Configure INAT rules

You can create, modify, or remove an INAT entry.

CLI procedures

To create an INAT entry by using the CLI:

At the command prompt, type the following commands to create an INAT entry and verify its configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **add inat** <name> <publicIP> <privateIP> [-**tcpproxy** (**ENABLED** | **DISABLED**)] [-**ftp** (**ENABLED** | **DISABLED**)] [-**usip** (**ON** | **OFF**)] [-**usnip** (**ON** | **OFF**)] [-**proxyIP** <**ip_addr > ipv6_addr>**]
- **show inat** [<name>]

Example:

```
> add inat ip4-ip4 172.16.1.2 192.168.1.1 -proxyip 10.102.29.171
 Done
```

To modify an INAT entry by using the CLI:

To modify an INAT entry, type the `set inat` command, the name of the entry, and the parameters to be changed, with their new values.

To remove an INAT configuration by using the CLI:

At the command prompt, type:

- **rm inat** <name>

Example:

```
> rm inat ip4-ip4
 Done
```

GUI procedures

To configure an INAT entry by using the GUI:

Navigate to **System** > **Network** > **NATs** > **INAT**, and add an INAT entry or edit an existing INAT entry.

To remove an INAT configuration by using the GUI:

Navigate to **System** > **Network** > **NATs** > **INAT**, delete the INAT configuration.

Connection failover for INAT rules

Connection failover or connection mirroring enables the primary node to duplicate connection and persistence information to the secondary node in a high availability. The state information of the connection is shared with the secondary node regularly when connection mirroring is enabled.

Enabling connection failover provides more reliability but it comes at the cost of some system time being used up for sharing the state information. The connection data is synchronized to the standby unit with every packet or flow state update. Hence, it must be used only at places where connection level reliability is of prime importance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Citrix ADC appliance high availability setups support connection failover for INAT connections. The primary node sends INAT mappings and other INAT-related connection information to the secondary node at regular intervals. The secondary appliance uses the mapping and connection information only in the event of a failover.

When a failover occurs, the new primary node has information about the INAT connections established before the failover. Hence, it continues to serve those connections even after the failover.

From the client's perspective the failover is transparent. During the transition period, the client and server might experience a brief disruption and retransmissions. Connection failover can be enabled per INAT rule.

For enabling connection failover on an INAT rule, you enable the `connFailover` parameter of that specific RNAT rule by using CLI.

CLI procedure

To enable connection failover for an INAT rule by using the CLI:

To enable connection failover while adding an INAT rule, at the command prompt, type:

- **add inat** <name> <publicIP> <privateIP> [-**tcpproxy** (**ENABLED** | **DISABLED**)] [-**ftp** (**ENABLED** | **DISABLED**)] [-**usip** (**ON** | **OFF**)] [-**usnip** (**ON** | **OFF**)] [-**proxyIP** <ip_addr|ipv6_addr>] -**connfailover** (**ENABLED** | **DISABLED**)
- **show inat** <name>

To enable connection failover while modifying an existing INAT rule, at the command prompt, type:

set inat -connfailover (**ENABLED** **DISABLED**)

-
- **show inat** <name>

Coexistence of INAT and Virtual Servers

September 14, 2021

If both INAT and RNAT are configured, the INAT rule takes precedence over the RNAT rule. If RNAT is configured with a network address translation IP (NAT IP) address, the NAT IP address is selected as the source IP address for that RNAT client.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The default public destination IP in an INAT configuration is the virtual IP (VIP) address of the Citrix ADC device. Virtual servers also use VIPs. When both INAT and a virtual server use the same IP address, the Vserver configuration overrides the INAT configuration.

Following are a few sample configuration setup scenarios and their effects.

Case	Result
You have configured a virtual server and a service to send all data packets received on a specific Citrix ADC port to the server directly. You have also configured INAT and enabled TCP. Configuring INAT in this manner sends all data packets received through a TCP engine before sending them to the server.	All packets received on the Citrix ADC, except those received on the specified port, pass through the TCP engine.
You have configured a virtual server and a service to send all data packets of service type TCP, that are received on a specific port on the Citrix ADC, to the server after passing through the TCP engine. You have also configured INAT and disabled TCP. Configuring INAT in this manner sends the data packets received directly to the server.	Only packets received on the specified port pass through the TCP engine.
You have configured a virtual server and a service to send all data packets received to either of two servers. You are attempting to configure INAT to send all data packets received to a different server.	The INAT configuration is not allowed.
You have configured INAT to send all received data packets directly to a server. You are attempting to configure a virtual server and a service to send all data packets received to two different servers.	The vserver configuration is not allowed.

Stateless NAT46

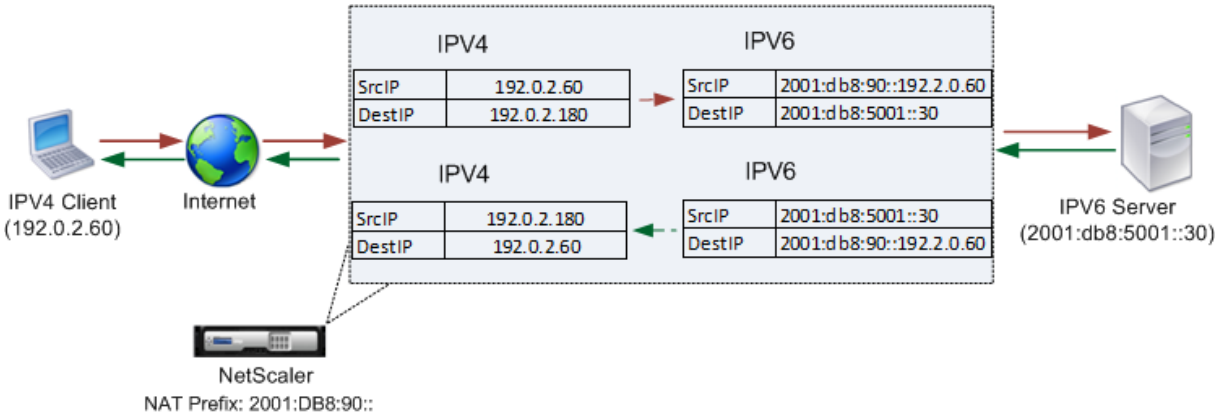
September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The stateless NAT46 feature enables communication between IPv4 and IPv6 networks through IPv4 to IPv6 packet translation, and vice versa, without maintaining any session information on the Citrix ADC appliance.

For a stateless NAT46 configuration, the appliance translates an IPv4 packet to IPv6 or an IPv6 packet to IPv4 as defined in RFCs 6145 and 2765.

A stateless NAT46 configuration on the Citrix ADC appliance has the following components:



- **IPv4-IPv6 INAT entry.** An INAT entry defining a 1:1 relationship between an IPv4 address and an IPv6 address. In other words, an IPv4 address on the appliance listens to connection requests on behalf of an IPv6 server. An IPv4 request packet for this IPv4 address is translated into an IPv6 packet, and then the IPv6 packet is sent to the IPv6 server.

  The appliance translates an IPv6 response packet into an IPv4 response packet with its source IP address field set as the IPv4 address specified in the INAT entry. The translated packet is then sent to the client.

- **NAT46 IPv6 prefix.** A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance. During IPv4 packet to IPv6 packet translation, the appliance sets the source IP address of the translated IPv6 packet to a concatenation of the NAT46 IPv6 prefix [96 bits] and the IPv4 source address [32 bits] that was received in the request packet.

  During IPv6 packet to IPv4 packet translation, the appliance sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv6 address. To enable communication between IPv4 clients and IPv6 server S1, Citrix ADC appliance NS1 is deployed with a stateless NAT46 configuration that includes an IPv4-IPv6 INAT entry for server S1, and a NAT46 Prefix. The INAT entry includes an IPv4 address at which the appliance listens to connection requests from IPv4 clients on behalf of the IPv6 server S1.

The following table lists the settings used in this example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entities	Name	Value
IP address of the client	Client_IPv4 (for reference purposes only)	192.0.2.60
IPv6 address of the server	Sevr_IPv6 (for reference purposes only)	2001:DB8:5001::30
IPv4 address defined in the INAT entry for IPv6 server S1	Map-Sevr-IPv4 (for reference purposes only)	192.0.2.180
IPv6 prefix for NAT 46 translation	NAT46_Prefix (for reference purposes only)	2001:DB8:90:

Following is the traffic flow in this example:

1. IPv4 Client CL1 sends a request packet to the Map-Sevr-IPv4 (192.0.2.180) address on the Citrix ADC appliance.
2. The appliance receives the request packet and searches the NAT46 INAT entries for the IPv6 address mapped to the Map-sevr-IPv4 (192.0.2.180) address. It finds the Sevr-IPv6 (2001:DB8:5001::30) address.
3. The appliance creates a translated IPv6 request packet with:
   - Destination IP address field = Sevr-IPv6 = 2001:DB8:5001::30
   - Source IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
4. The appliance sends the translated IPv6 request to Sevr-IPv6.
5. The IPv6 server S1 responds by sending an IPv6 packet to the Citrix ADC appliance with:
   - Destination IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits)= 2001:DB8:90::192.0.2.60
   - Source IP address field = Sevr-IPv6 = 2001:DB8:5001::30
6. The appliance receives the IPv6 response packet and verifies that its destination IP address matches the NAT46 prefix configured on the appliance. Because the destination address matches the NAT46 prefix, the appliance searches the NAT46 INAT entries for the IPv4 address associated with the Sevr-IPv6 address (2001:DB8:5001::30). It finds the Map-Sevr-IPv4 address (192.0.2.180).
7. The appliance creates an IPv4 response packet with:
   - Destination IP address field = The NAT46 prefix stripped from the destination address of the IPv6 response = Client_IPv4 (192.0.2.60)
   - Source IP address field = Map-Sevr-IPv4 address (192.0.2.180)
8. The appliance sends the translated IPv4 response to client CL1.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Limitations of Stateless NAT46

The following limitations apply to stateless NAT46:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv4 packets is not supported.
- Translation of multicast packets is not supported.
- Translation of destination option headers and source routing headers is not supported.
- Translation of fragmented IPv4 UDP packets that do not contain UDP checksum is not supported.

Configure Stateless NAT46

Creating the required entities for stateless NAT46 configuration on the Citrix ADC appliance involves the following procedures:

1. Create an IPv4-IPv6 mapping INAT entry with stateless mode enabled.
2. Create a NAT46 IPv6 prefix.

CLI procedures

To configure an INAT mapping entry by using the CLI:

At the command prompt, type:

- add inat <name> <publicIPv4> <privateIPv6> -mode STATELESS
- show inat <name>

To create an NAT46 prefix by using the CLI:

At the command prompt, type:

```
set inatparam -nat46v6Prefix <ipv6_addr                *>
```

-
- show inatparam

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
 > add inat exmpl-com-stls-nat46 192.0.2.180
2001:DB8:5001::30 -mode stateless
Done

> set inatparam -nat46v6Prefix 2001:DB8:90::/96
Done
```

GUI procedures

To create an INAT mapping entry by using the GUI:

1. Navigate to System > Network > Routes > INAT.
2. Add a new INAT entry, or edit an existing INAT entry.
3. Set the following parameters:
   - Name*
   - Public IP Address*
   - Private IP Address* (Select the IPv6 check box and enter the address in IPv6 format.)
   - Mode (Select Stateless from the drop down list.)

   * A required parameter

To create a NAT46 prefix by using the GUI:

Navigate to **System** > **Network**, in the **Settings** group, click **Configure INAT Parameters**, and set the **Prefix** parameter.

Setting Global Parameters for Stateless NAT46

The appliance provides some optional global parameters for stateless NAT46 configurations.

To set global parameters for stateless NAT46 by using the CLI:

At the command prompt, type:

set inatparam [-**nat46IgnoreTOS** (**YES** | **NO**)] [-**nat46ZeroCheckSum** (**ENABLED** | **DISABLED**)] [-**nat46v6Mtu**

-
- **show inatparam**

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
1 > set inatparam -nat46IgnoreTOS YES -nat46ZeroCheckSum DISABLED -
     nat46v6Mtu 1400 -nat46FragHeader DISABLED
2  Done
```

To set global parameters for stateless NAT46 by using the GUI:

Navigate to **System** > **Network**, in the **Settings** group, click **Configure INAT Parameters**.

DNS64

September 14, 2021

The Citrix ADC DNS64 feature responds with a synthesized DNS AAAA record to an IPv6 client sending an AAAA request for an IPv4-only domain. The DNS64 feature is used with the NAT64 feature to enable seamless communication between IPv6-only clients and IPv4-only servers. DNS64 enables discovery of the IPv4domain by the IPV6 only clients, and NAT64 enables communication between the clients and servers.

For synthesizing an AAAA record, the Citrix ADC appliance fetches a DNS A record from a DNS server. The DNS64 prefix is a 96-bit IPv6 prefix configured on the Citrix ADC appliance. The Citrix ADC appliance synthesizes the AAAA record by concatenation of the DNS64 Prefix (96 bits) and the IPv4 address (32 bits).

For enabling communication between IPv6 clients and IPv4 servers, a Citrix ADC appliance with DNS64 and NAT64 configuration can deployed either on the IPv6 client side or on the IPv4 server side. In both cases, the DNS64 configuration on the Citrix ADC appliance is similar and includes a load balancing virtual server acting as a proxy server for DNS servers. If the Citrix ADC appliance is deployed on the client side, the load balancing virtual server must be specified, on the IPv6 client, as the nameserver for a domain.

Consider an example where a Citrix ADC appliance with DNS64 and NAT64 configuration is configured on the IPv4 side. In this example, an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, Citrix ADC appliance NS1 is deployed with a DNS64 and stateful NAT64 configuration.

The DNS64 configuration includes DNS load balancing virtual server LBVS-DNS64-1, on which the DNS64 option is enabled. A DNS64 policy named DNS64-Policy-1, and an associated DNS64 action named DNS64-Action-1, are also configured on NS1, andDNS64-Policy-1 is bound to LBVS-DNS64-1. LBVS-DNS64-1 acts as a DNS proxy server for DNS servers DNS-1 and DNS-2.

When traffic arriving at LBVS-DNS64-1 matches the conditions specified in DNS64-Policy-1, the traffic is processed according to the settings in DNS64-Action-1. DNS64-Action-1 specifies the DNS64 prefix used, with the A record received from a DNS server, to synthesize an AAAA record.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The global DNS parameter cacherecords is enabled on the Citrix ADC appliance, so the appliance caches DNS records. This setting is necessary for the DNS64 to work properly.

The following table lists the settings used in the above example: DNS64 example settings.

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a DNS AAAA request for the IPv6 address of the site www.example.com.
2. The request is received by the DNS load balancing virtual server LBVS-DNS64-1 on Citrix ADC appliance NS1.
3. NS1 checks its DNS cache records for the requested AAAA record and finds that AAAA record for the site www.example.com does not exist in the DNS cache.
4. LBVS-DNS64-1's load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
5. Because the site www.example.com is hosted on an IPv4 server, the DNS server DNS-1 does not have any AAAA record for the site www.example.com.
6. DNS-1 sends either an empty DNS AAAA response or an error message to LBVS-DNS64-1.
7. Because DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of www.example.com.
8. DNS-1 responds by sending the DNS A record for www.example.com to LBVS-DNS64-1. The A record includes the IPv4 address for www.example.com.
9. NS1 synthesizes an AAAA record for the site www.example.com with:
    - IPv6 address for site www.example.com = Concatenation of DNS64 Prefix (96 bits) specified in the associated DNS64action, and IPv4 address of DNS A record (32 bits) = 2001:DB8:300::192.0.2.60
10. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

Points to Consider for a DNS64 Configuration

Before configuring DNS64 on a Citrix ADC appliance, consider the following points:

- The DNS64 feature of the Citrix ADC appliance is compliant with RFC 6174.
- The DNS64 feature of the Citrix ADC appliance does not support DNSSEC. The Citrix ADC appliance does not synthesize an AAAA record from a DNSSEC response received from a DNS server. A response is classified as a DNSSEC response, only if it contains RRSIG records.
- The Citrix ADC appliance supports DNS64 prefix of length of only 96 bits.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Though the DNS64 feature is used with the NAT64 feature, the DNS64 and NAT64 configurations are independent on the Citrix ADC appliance. For a particular flow, you must specify the same IPv6 prefix value for the DNS64 prefix and the NAT64 prefix parameters, so that the synthesized IPv6 addresses received by the client are routed to the particular NAT64 configuration. For more information on configuring NAT64 on a Citrix ADC appliance, see Stateful NAT64.
- The following are the different cases of DN64 processing by the Citrix ADC appliance:
  - If the AAAA response from the DNS server includes AAAA records, then each record in the response is checked for the set of exclusion rule configured on the Citrix ADC appliance for the particular DNS64 configuration. The Citrix ADC removes the IPv6 addresses, whose prefix matches the exclusion rule, from the response. If the resulting response includes at least one IPv6 record, the Citrix ADC appliance forwards this response to the client, else, the appliance synthesizes a AAAA response from the A record of the domain and sends it to the IPv6 client.
  - If the AAAA response from the DNS server is an empty answer response, the appliance requests for A resource records with the same domain name or searches in its own records if the appliance is an authentic domain name server for the domain. If the request results in an empty answer or error, the same is forwarded to the client.
  - If the response from the DNS server includes RCODE=1 (format error), the Citrix ADC appliance forwards the same to the client. If there is no response before the timeout, the Citrix ADC appliance sends a response with RCODE=2 (server failure) to the client.
  - If the response from the DNS server includes a CNAME, the chain is followed until the terminating A or AAAA record is reached. If the CNAME does not have any AAAA resource records, the Citrix ADC appliance fetches the DNS A record to be used for synthesizing AAAA record. The CNAME chain is added to the answer section along with the synthesized AAAA record and then sent to the client.
- The DNS64 feature of the Citrix ADC appliance also supports responding to PTR request. When a PTR request for a domain of an IPv6 address is received on the appliance and the IPv6 address matches any of the configured DNS64 prefix, the appliance creates a CNAME record mapping the IP6-ARPA domain into the corresponding IN-ADDR. ARPA domain and the newly formed IN-ADDR.ARPA domain is used for resolution. The appliance searches the local PTR records and if the records are not present, the appliance sends a PTR request for IN-ADDR.ARPA domain to the DNS server. The Citrix ADC appliance uses the response from the DNS server to synthesize response for the initial PTR request.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuration Steps

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

- **Add DNS services.** DNS services are logical representation of DNS servers for which the Citrix ADC appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see Load Balancing.
- **Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy.** A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing according to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude rule and mapped rule settings.
- **Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it.** The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see Load Balancing.

  Note: The CLI has separate commands for these two tasks, but the GUI combines them in a single dialog box.

  Enable caching of DNS records. Enable the global parameter for the Citrix ADC appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see Domain Name System.

CLI procedures

To create a service of type DNS by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> …

To create a DNS64 action by using the CLI:

At the command prompt, type:

- add dns action64 <actionName> -Prefix <ipv6_addr|*> [-mappedRule <expression>] [-excludeRule <expression>]

To create a DNS64 policy by using the CLI:

At the command prompt, type:

- add dns policy64 <name> -rule <expression> -action <string>

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To create a DNS load balancing virtual server by using the CLI:

At the command prompt, type:

- add lb vserver <name> DNS <IPAddress> <port> -dns64 (ENABLED | DISABLED) [-bypassAAAA (YES | NO)] …

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the CLI:

At the command prompt, type:

- bind lb vserver <name> <serviceName> …
- bind lb vserver <name> -policyName <string> -priority <positive_integer> …

GUI procedures

To create a service of type DNS by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services, and add a new service.
2. Set the following parameters:
    - Service Name*
    - Server*
    - Protocol* (Select DNS from the drop down list.)
    - Port*

To create a DNS64 action by using the GUI:

Navigate to Traffic Management > DNS > Actions, on the DNS Actions64 tab, add a new DNS64 action.

To create a DNS64 policy by using the GUI:

Navigate to Traffic Management > DNS > Policies, on the DNS Policies64 tab, add a new DNS64 policy.

To create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a new virtual server.
2. Set the following parameters:
    - Name*
    - IP Address*
    - Protocol* (Select DNS from the drop down list.)
    - Port*
3. Select the Enable DNS64 option.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. In the Services pane, bind the service to the virtual server.
5. In the Policies pane, bind the policy to the virtual server.

Sample Configuration

```
 > add service SVC-DNS-1 203.0.113.50 DNS 53
 Done

> add service SVC-DNS-2 203.0.113.60 DNS 53
 Done

> add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96
 Done

> add dns Policy64 DNS64-Policy-1 -rule "CLIENT.IPv6.SRC.IN_SUBNET
   (2001:DB8:5001::/64)"
-action DNS64-Action-1
 Done

> add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED
 Done

> bind lb vserver LBVS-DNS64-1 SVC-DNS-1
 Done

> bind lb vserver LBVS-DNS64-1 SVC-DNS-2
 Done

> bind lb vserver LBVS-DNS64-1 -policyname DNS64-Policy-1 -priority 2
 Done
```

Stateful NAT64 Translation

September 14, 2021

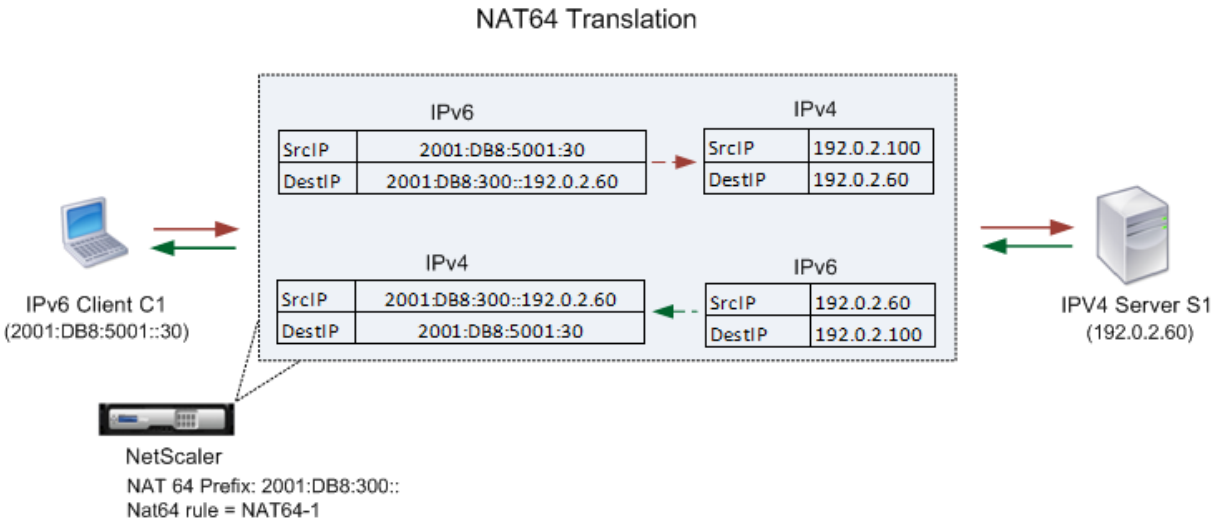
The stateful NAT64 feature enables communication between IPv6 clients and IPv4 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the Citrix ADC appliance.

A stateful NAT64 configuration on the Citrix ADC appliance has the following components:

- **NAT64 rule**—An entry consisting of an ACL6 rule and a netprofile, which consists of a pool of Citrix ADC owned SNIP Addresses.
- **NAT64 IPv6 Prefix**—A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: Currently the Citrix ADC appliance supports only one prefix to be used commonly with all NAT 64 rules.



The Citrix ADC appliance considers an incoming IPv6 packet for NAT64 translation when all of the following conditions are met:

- The incoming IPv6 packet matches the ACL6 rule bound to a NAT64 rule.
- The destination IP address of the IPv6 packet matches the NAT64 IPv6 prefix.

When an IPv6 request packet received by the Citrix ADC appliance matches an ACL6 defined in a NAT64 rule and the destination IP of the packet matches the NAT64 IPv6 prefix, the Citrix ADC appliance considers the IPv6 packet for translation.

The appliance translates this IPv6 packet to an IPv4 packet with a source IP address matching one of the IP address bound to the netprofile defined in the NAT64 rule, and a destination IP address consisting of the last 32 bits of the destination IPv6 address of the IPv6 request packet. The Citrix ADC appliance creates a NAT64 session for this particular flow and forwards the packet to the IPv4 server. Subsequent responses from the IPv4 server and requests from the IPv6 client are translated accordingly by the appliance, on the basis of information in the particular NAT64 session.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, Citrix ADC appliance NS1 is deployed with a stateful NAT64 configuration that includes a NAT64 rule and a NAT64 prefix. A mapped IPv6 address of server S1 is formed by concatenating the NAT64 IPv6 prefix [96 bits] and the IPv4 source address [32 bits]. This mapped IPv6 address is then manually configured in the DNS servers. The IPv6 clients get the mapped IPv6 address from the DNS servers to communicate withIPv4 server S1.

The following table lists the settings used in this example: Stateful NAT64 translation example settings.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a request packet to Map-Sevr-IPv6 (2001:DB8:300::192.0.2.60) address.
2. The Citrix ADC appliance receives the request packet. If the request packet matches the ACL6 defined in the NAT64 rule, and the destination IP address of the packet matches the NAT64 IPv6 prefix, the Citrix ADC considers the IPv6 packet for translation.
3. The appliance creates a translated IPv4 request packet with:
    - Destination IP address field containing the NAT64 prefix stripped from the destination address of the IPv6 request (Sevr_IPv4 = 192.0.2.60)
    - Source IP address field containing one of the IPv4 address bound to Netprofile-1(in this case, 192.0.2.100)
4. The Citrix ADC appliance creates a NAT64 session for this flow and sends the translated IPv4 request to server S1.
5. IPv64 server S1 responds by sending an IPv4 packet to the Citrix ADC appliance with:
    - Destination IP address field containing 192.0.2.100
    - Source IP address field containing the address ofSevr_IPv4(192.0.2.60)
6. The appliance receives the IPv4 response packet, searches all the session entries, and finds that the IPv6 response packet matches the NAT64 session entry created in step 4. The appliance considers the IPv4 packet for translation.
7. The appliance creates a translated IPv6 response packet with:
    - Destination IP address field=Client_IPv6=2001:DB8:5001::30
    - Source IP address field = Concatenation of NAT64 Prefix (First 96 bits) and Sevr_IPv4 (last 32 bits) =2001:DB8:300::192.0.2.60
8. The appliance sends the translated IPv6 response to client CL1.

Limitations of Statelful NAT64

The following limitations apply to stateful NAT64:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv6 packets is not supported.
- Translation of multicast packets is not supported.
- Packets of Stream Control Transmission Protocol (SCTP), Datagram Congestion Control Protocol (DCCP), and IPSec, are not translated.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring Stateful NAT64

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

1. Add an ACL6 rule with action ALLOW.
2. Add an ipset, which binds multiple IP addresses.
3. Add a netprofile and bind the ipset to it. If you want to bind only one IP address, you need not create an ipset entity. In that case, bind the IP address directly to the netprofile.
4. Add a NAT64 rule, which includes binding the ACl6 rule and the netprofile to the NAT 64 rule.
5. Add a NAT64 IPv6 prefix.

CLI procedures

To add an ACL6 rule by using the CLI:

At the command prompt, type:

- add ns acl6 <acl6name> <acl6action> …

To add an IPset and bind multiple IPs to it by using the CLI:

At the command prompt, type:

- add ipset <name>
- bind ipset <name> <IPaddress …>

To add a netprofile by using the CLI:

At the command prompt, type:

- add netprofile <name> -srcIP <IPaddress or IPset>

To add a NAT64 rule by using the CLI:

At the command prompt, type:

- add nat64 <name> <acl6name> -netProfile <string>

To add a NAT64 prefix by using the CLI:

At the command prompt, type:

set ipv6 -natprefix <ipv6_addr *>

-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
 > add acl6 ACL6-1 ALLOW -srcIPv6 2001:DB8:5001::30
 Done

> apply acls6
 Done

> add ip 192.0.2.100 255.255.255.0  – type SNIP
 Done

> add ip 192.0.2.102 255.255.255.0   – type SNIP
 Done

> add ipset IPset-1
 Done

> bind ipset IPset-1 192.0.2.100 192.0.2.102
IPAddress "192.0.2.100" bound
IPAddress "192.0.2.102" bound
 Done

> add netprofile Netprofile-1 -srcIP IPset-1
 Done

> add nat64 NAT64-1 ACL6-1 -netprofile Netprofile-1
 Done

> set ipv6 -natprefix 2001:DB8:300::/96
 Done
```

GUI procedures

To add a NAT64 rule by using the GUI:

Navigate to System > Network > Routes > NAT64, and a new NAT64 rule, or edit an existing rule.

To add a NAT64 prefix by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

RNAT

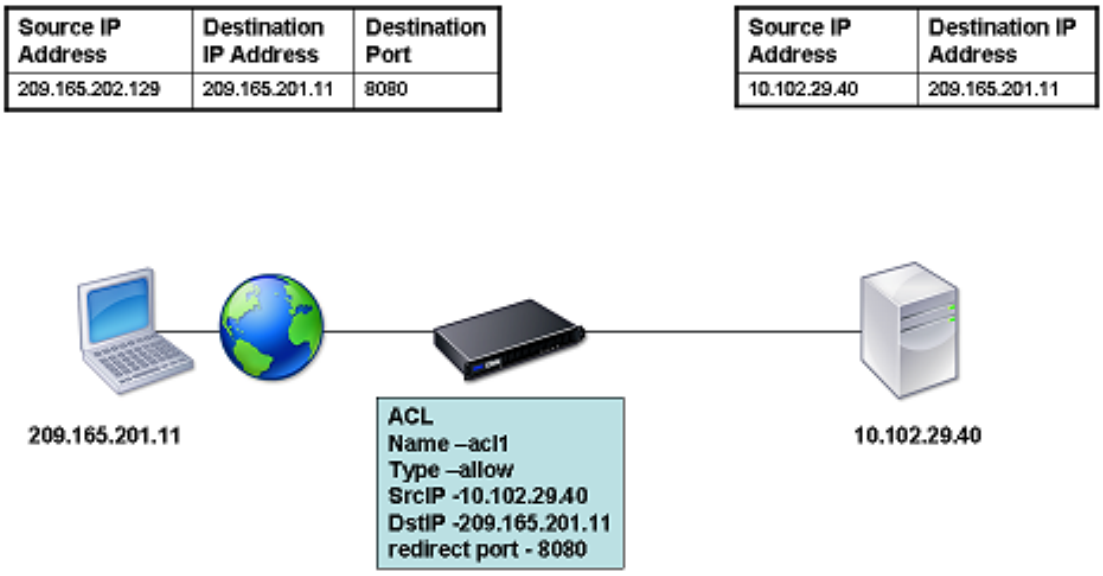
September 14, 2021

In Reverse Network Address Translation (RNAT), the Citrix ADC appliance replaces the source IP addresses in the packets generated by the servers with public NAT IP addresses. By default, the appli-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

ance uses a SNIP address as the NAT IP address. You can also configure the appliance to use a unique NAT IP address for each subnet. You can also configure RNAT by using Access Control Lists (ACLs). Use Source IP (USIP), Use Subnet IP (USNIP), and Link Load Balancing (LLB) modes affect the operation of RNAT. You can display statistics to monitor RNAT.

Note: The ephemeral port range for RNAT on the Citrix ADC appliance is 1024-65535.



You can use either a network address or an extended ACL as the condition for an RNAT entry:

- **Using a Network address.** When you use a network address, RNAT processing is performed on all of the packets coming from the specified network.
- **Using Extended ACLs.** When you use ACLs, RNAT processing is performed on all packets that match the ACLs. To configure the Citrix ADC appliance to use a unique IP address for traffic that matches an ACL, you must perform the following three tasks:

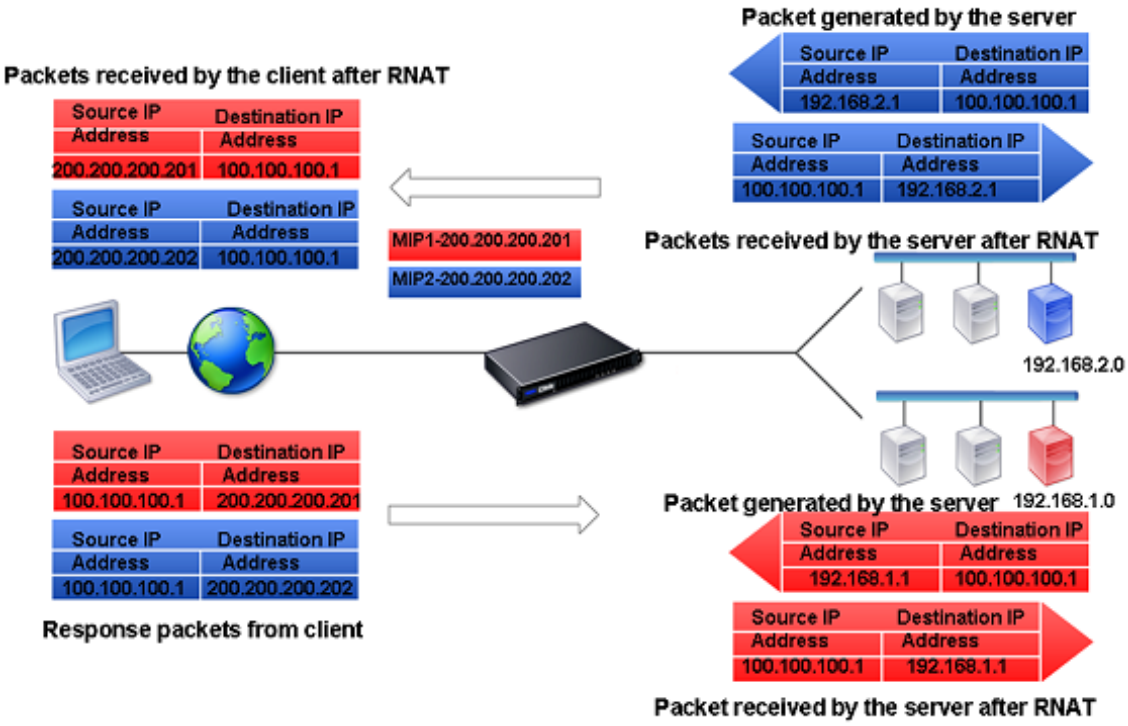
  1. Configure the ACL.
  2. Configure RNAT to change the source IP address and Destination Port.
  3. Apply the ACL.

  The following diagram illustrates RNAT configured with an ACL.

  Figure 1. RNAT with an ACL

You have the following basic choices for the type of NAT IP address:

- **Using a SNIP as the NAT IP Address.** When using a SNIP as the NAT IP address, the Citrix ADC appliance replaces the source IP addresses of server-generated packets with the a SNIP. There-



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

fore, the SNIP address must be a public IP address. If Use Subnet IP (USNIP) mode is enabled, the Citrix ADC can use a subnet IP address (SNIP) as the NAT IP address.

- **Using a Unique IP Address as the NAT IP Address.** When using a unique IP address as the NAT IP address, the Citrix ADC appliance replaces the source IP addresses of server-generated packets with the unique IP address specified. The unique IP address must be a public Citrix ADC-owned IP address. If multiple NAT IP addresses are configured for a subnet, NAT IP selection uses the round robin algorithm.

  This configuration is illustrated in the following diagram.

  Figure 2. Using a Unique IP Address as the NAT IP Address

Before you begin

Before configuring a RNAT rule, consider the following points:

- When RNAT and Use Source IP (USIP) are both configured on the Citrix ADC appliance, RNAT takes precedence. In other words, the source IP address of the packets, which matches a RNAT rule, is replaced according to the setting in the RNAT rule.
- In a topology where the Citrix ADC appliance performs both Link Load Balancing (LLB) and RNAT for traffic originating from the server, the appliance selects the source IP address based on the router. The LLB configuration determines selection of the router. For more information about LLB, see Link Load Balancing.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure RNAT

The following instructions provide separate command-line procedures for creating RNAT entries that use different conditions and different types of NAT IP addresses. In the GUI, all of the variations can be configured in the same dialog box, so there is only one procedure for GUI users.

CLI procedures

To create an RNAT rule by using the CLI:

At the command prompt, to create the rule and verify the configuration, type:

- `add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))`
- `bind rnat <name> <natIP>@ ...`
- `show rnat`

To modify or remove an RNAT rule by using the CLI:

- To modify an RNAT rule:

  `set rnat <name> (<aclname> [-redirectPort <port>])`

- To remove an RNAT rule, type the command.

  `rm rnat <name>`

Use the following command to verify the configuration:

- `show rnat`

Examples:

```
A network address as the condition and a SNIP address as the NAT IP
    address:

> add rnat RNAT-1 192.168.1.0 255.255.255.0
Done

A network address as the condition and a unique IP address as the NAT
    IP address:

> add rnat RNAT-2 192.168.1.0 255.255.255.0
Done

> bind rnat RNAT-2 -natip 10.102.29.50
Done

If instead of a single NAT IP address you specify a range, RNAT entries
     are created with all the Citrix ADC-owned IP addresses, except the
    NSIP, that fall within the range specified:
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
15
16 > add rnat RNAT-3 192.168.1.0 255.255.255.0
17 Done
18
19 > bind rnat RNAT-3 -natip 10.102.29.[50-110]
20 Done
21
22
23 An ACL as the condition and a SNIP address as the NAT IP address:
24
25 > add rnat RNAT-4 acl1
26 Done
27
28 An ACL as a condition and a unique IP address as the NAT IP address:
29
30 > add rnat RNAT-4 acl1
31 Done
32
33 > bind rnat RNAT-4 -natip 10.102.29.50
34 Done
35
36 If instead of a single NAT IP address you specify a range, RNAT entries
       are created with all the Citrix ADC-owned IP addresses, except the
      NSIP, that fall within the range specified:
37
38 > add rnat RNAT-5 acl1
39 Done
40
41 > bind rnat RNAT-5 -natip 10.102.29.[50-70]
42 Done
```

GUI procedures

To create an RNAT entry by using the GUI:

Navigate to **System** > **Network** > **NATs**, click the **RNAT** tab, and add a new RNAT rule, or edit an existing rule.

Monitor RNAT

You can display RNAT statistics to troubleshoot issues related to IP address translation.

The following table describes the statistics associated with RNAT and RNAT IP.

Statistic	Description
Bytes received	Bytes received during RNAT sessions

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Statistic	Description
Bytes sent	Bytes sent during RNAT sessions
Packets received	Packets received during RNAT sessions
Packets sent	Packets sent during RNAT sessions
Syn sent	Requests for connections sent during RNAT sessions
Current sessions	Currently active RNAT sessions

To view RNAT statistics by using the CLI:

At the command prompt, type:

- **stat rnat**

Example:

```
> stat rnat

RNAT summary
                                Rate (/s)            Total
Bytes Received                    0                    0
Bytes Sent                        0                    0
Packets Received                  0                    0
Packets Sent                      0                    0
Syn Sent                          0                    0
Current RNAT sessions            --                    0
 Done
>
```

To monitor RNAT by using the GUI:

Navigate to **System** > **Network** > **NATs**, click the **RNAT** tab, and then click **Statistics**.

Configure RNAT6

Reverse Network Address Translation (RNAT) rules for IPv6 packets are called RNAT6s. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination. The NAT IPv6 address is one of the Citrix ADC owned SNIP6 or VIP6 addresses.

When configuring an RNAT6 rule, you can specify either an IPv6 prefix or an ACL6 as the condition:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Using a IPv6 network address**. When you use an IPv6 prefix, the appliance performs RNAT processing on those IPv6 packets whose IPv6 address matches the prefix.
- **Using ACL6s**. When you use an ACL6, the appliance performs RNAT processing on those IPv6 packets that match the conditions specified in the ACL6.

You have one of the following options to set the NAT IP address:

- Specify a set of Citrix ADC owned SNIP6 and VIP6 addresses for an RNAT6 rule. The Citrix ADC appliance uses any one of the IPv6 addresses from this set as a NAT IP address for each session. The selection is based on the round robin algorithm and is done for each session.
- Do not specify any Citrix ADC owned SNIP6 or VIP6 address for an RNAT6 rule. The Citrix ADC appliance uses any one of the Citrix ADC owned SNIP6 or VIP6 addresses as a NAT IP address. The selection is based on the next hop network to which an IPv6 packet that matches the RNAT rule is destined.

CLI procedures

To create an RNAT6 rule by using the CLI:

At the command prompt, to create the rule and verify the configuration, type:

- **add rnat6** <name> (<network> | (<acl6name> [-**redirectPort** <port>]))
- **bind rnat6** <name> <natIP6>@ …
- **show rnat6**

To modify or remove an RNAT6 rule by using the CLI:

- To modify an RNAT6 rule whose condition is an ACL6, type the **set rnat6** <name> command, followed by a new value for the **redirectPort** parameter.
- To remove an RNAT6 rule, type the **clear rnat6** <name> command.

GUI procedures

To configure an RNAT6 rule by using the GUI:

Navigate to **System** > **Network** > **NATs**, click the **RNAT6** tab, and add a new RNAT6 rule, or edit an existing rule.

Monitor RNAT6

You can display statistics related to the RNAT6 feature to monitor the performance or to troubleshoot problems related to RNAT6 feature. You can display a summary of statistics of the RNAT6 rules or of

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

a particular RNAT6 rule. The statistical counters reflect events since the Citrix ADC appliance was last restarted. All these counters are reset to 0 when the Citrix ADC appliance is restarted.

The following lists some of the statistics counters associated with the RNAT6 feature:

- **Bytes received** - Total bytes received during RNAT6 sessions.
- **Bytes sent** - Total number of bytes sent during RNAT6 sessions.
- **Packets received** - Total number of packets received during RNAT6 sessions.
- **Packets sent** - Total number of packets sent during RNAT6 sessions.
- **Syn sent** - Total number of requests for connections sent during RNAT6 sessions
- **Current sessions** - Currently active RNAT6 sessions

To display a summarized statistics of all RNAT6 rules by using the CLI:

At the command prompt, type:

- **stat rnat6**

To display statistics for a specified RNAT6 rule by using the CLI:

At the command prompt, type:

- **stat rnat6** [<rnat6 rule name>]

To display RNAT6 statistics by using the GUI:

Navigate to **System** > **Network** > **NATs**, click the **RNAT6** tab, and then click **Statistics**.

```
> stat rnat6

RNAT6 summary

                          Rate (/s)               Total

Bytes Received             178                20644

Bytes Sent                 178                20644

Packets Received            5                  401

Packets Sent                5                  401

Syn Sent                    0                    2

Current RNAT6 sessions      --                   1

Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Log Start Time and Connection Closure Reasons in RNAT Log Entries

For diagnosing or troubleshooting problems related to RNAT, the Citrix ADC appliance logs RNAT sessions whenever they are closed.

A log message for an RNAT session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp of log creation
- Protocol of the RNAT session
- Source IP address
- RNAT IP address
- Destination IP address
- Start time of the RNAT session
- Closing time of the RNAT session
- Total bytes sent by the Citrix ADC appliance for this RNAT session
- Total bytes received by the Citrix ADC appliance for this RNAT session
- Reason for closure of the RNAT session. The Citrix ADC appliance logs closure reason for TCP RNAT sessions that do not use the TCP proxy (TCP proxy disabled) of the appliance. The following are the type of closure reasons that are logged for TCP RNAT sessions:
  - **TCP FIN**. The RNAT session was closed because of a TCP FIN sent by either the source or destination device.
  - **TCP RST**. The RNAT session was closed because of a TCP Reset that was sent by either the source or destination device.
  - **TIMEOUT**. The RNAT session timed out.

The following table shows some sample log entries for RNAT sessions.

Type of Entry	Sample Log Entry
Sample log entry for UDP RNAT session	Dec 1 15:28:12 10.102.53.114 12/01/2015:15:28:12 GMT 0-PPE-0 : default UDP NAT_OTHERCONN_DELINK 154 0 : Source 1.2.2.5:23431 - Destination 192.168.123.122:22 - NatIP 192.168.123.1:4045 - Destination 192.168.123.122:22 - Start Time 12/01/2015:15:26:58 GMT - Delink Time 12/01/2015:15:28:12 GMT - Total_bytes_send 2511 - Total_bytes_recv 3725

Stateful Connection Failover for RNAT

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. The Citrix ADC appliance now supports stateful connection failover for connections related to RNAT rules in a Citrix ADC High Availability (HA) setup. In an HA setup, connection failover (or connection mirroring) refers to the process of keeping an established TCP or UDP connection active when a failover occurs.

The primary appliance sends messages to the secondary appliance to synchronize current information about the RNAT connections. The secondary appliance uses this connection information only in the event of a failover. When a failover occurs, the new primary Citrix ADC appliance has information about the connections established before the failover and hence continues to serve those connections even after the failover. From the client's perspective this failover is transparent. During the transition period, the client and server may experience a brief disruption and retransmissions.

Connection failover can be enabled per RNAT rule. For enabling connection failover on an RNAT rule, you enable the connFailover (Connection Failover) parameter of that specific RNAT rule by using either CLI or GUI.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable connection failover for a RNAT rule by using the CLI:

At the command prompt, type:

- `set rnat <name> -connfailover (ENABLED | DISABLED)`
- `show rnat`

To enable connection failover for a RNAT rule by using the GUI:

1. Navigate to **System** > **Network** > **NATs**, and then click the **RNAT** tab.
2. Select **Connection Failover** while adding a new RNAT rule, or while editing an existing rule.

Reserving the source port for RNAT connections to servers

For a request hitting an RNAT configuration that has one or more RNAT IP addresses and Use Proxy port parameter disabled, the Citrix ADC appliance uses one of the RNAT IP address and the source port of the RNAT request for connecting to servers. Prior to the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the same source port is already been used in some other connections.

- **Source port less than 1024**. By default, the Citrix ADC appliance reserves the first 1024 ports of any Citrix ADC owned IP address (including RNAT IP addresses). Prior to 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the source port of the RNAT request is less than or equal to 1024. With the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server succeeds even if the source port of the RNAT request is less than or equal to 1024.
- **Source port greater than 1024**. Prior to the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the same source port is already been used in some other connections. With 13.0 47.x build, you can specify a range of RNAT client source ports in the `Retain Source Port range` (`retainsourceportrange`) parameter as part of an RNAT configuration. The Citrix ADC appliance reserves these RNAT client source ports on the RNAT IP address to be used only for RNAT connection to servers.

Removing RNAT Sessions

You can remove any unwanted or inefficient RNAT sessions from the Citrix ADC appliance. The appliance immediately releases resources (such as the port of the NAT IP address, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected RNAT sessions from the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To clear all RNAT sessions by using the CLI:

At the command prompt, type:

- **flush rnatsession**

To clear selective RNAT sessions by using the CLI:

At the command prompt, type:

- **flush rnatsession** ((-**network** <ip_addr> -**netmask** <netmask>) | -**natIP** <ip_addr> | -**aclname** <string>)

To clear all or selective RNAT sessions by using the GUI:

1. Navigate to **System** > **Network** > **NATs**, and then click the **RNAT** tab.
2. In the **Actions** Menu, click **Flush RNAT Sessions** to remove all or selective RNAT sessions (for example, removing RNAT sessions with a specific RNAT IP, or belonging to a specific Network or ACL based RNAT rule).

Sample Configurations:

```
1     Clear all RNAT sessions existing on a Citrix ADC appliance
2
3     > flush rnatsession
4
5     Done
6
7     Clear all RNAT sessions belonging to network based RNAT rules that
         has 203.0.113.0/24 network as the matching condition.
8
9     > flush rnatsession -network 203.0.113.0 -netmask 255.255.255.0
10
11    Done
12
13    Clear all RNAT sessions with RNAT IP 192.0.2.90.
14
15    > flush rnatsession -natIP 192.0.2.90
16
17    Done
18
19    Clear all RNAT sessions belonging to ACL based RNAT rules that has
         ACL-RNAT-1 as the matching condition.
20
21    > flush rnatsession -aclname ACL-RNAT-1
22
23    Done
```

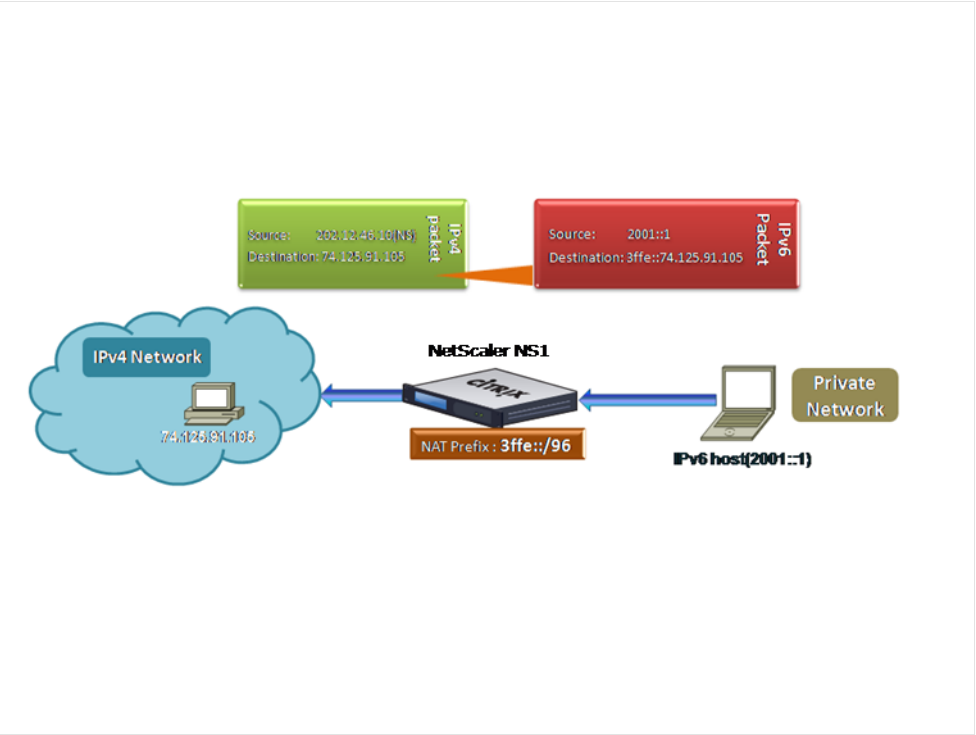
Configuring Prefix-Based IPv6-IPv4 Translation



September 14, 2021

Prefix-based translation is a process of translating packets sent from private IPv6 servers into IPv4 packets, using an IPv6 prefix configured in the Citrix ADC appliance. This prefix has a length of 96 bits (128-32=96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix.

The Citrix ADC appliance compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix. If there is a match, the Citrix ADC appliance generates an IPv4 packet and sets the destination IP address as the last 32 bits of the destination IP address of the matched IPv6 packet. IPv6 packets addressed to this prefix have to be routed to the Citrix ADC so that the IPv6-IPv4 translation is done by the Citrix ADC.

In the following diagram, 3ffe::/96 is configured as the IPv6 NAT prefix on Citrix ADC NS1. The IPv6 host sends an IPv6 packet with destination IP address 3ffe::74.125.91.105. NS1 compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix, and they match. NS1 then generates an IPv4 packet and sets the destination IP address as 74.125.91.105.

Figure 1. IPv6-IPv4 Prefix-Based Translation

To configure prefix-based IPv6-IPv4 translation by using the CLI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

At the command prompt, type:

set ipv6 [-natprefix <ipv6_addr *>]

-
- show ipv6

Example:

```
> set ipv6 -natprefix 3ffe::/96
 Done
```

To configure prefix-based IPv6-IPv4 translation by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

IP Prefix NAT

September 14, 2021

The Citrix ADC appliance supports translating a part of the source IP address instead of the complete address of packets received on the appliance. IP prefix NAT includes changing one or more octets or bits of the source IP address.

The Citrix ADC appliance supports IP prefix NAT for load balancing configurations of the following types: ANY, UDP, DNS, TCP, and HTTP.

Use Case: Zonification of Clients for a Deployment of a Citrix ADC appliance and an Optimization Device

IP prefix NAT is very useful in a deployment that includes a Citrix ADC appliance and an optimization device (for example, Citrix ByteMobile). This type of deployment has different geographically located client networks, which share the same network address. The Citrix ADC appliance must send the traffic received from each of the client networks to the optimization device before forwarding to the destination.

The device sends the optimized traffic back to the Citrix ADC appliance. Because the optimization requirement is different for traffic from each client network, the optimization device must recognize the client network of each packet that it receives. The solution is to segregate traffic from each client

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

network into a different zone by using VLANs. IP prefix NAT with a different setting is configured for each zone. The Citrix ADC appliance translates the last octet of the source IP address of every packet, and the translated octet value is different for each zone.

Consider an example of two zones, Z1 and Z2, sharing network address 192.0.2.0/24. On the Citrix ADC appliance, IP prefix NAT entities named natrule-1 and natrule-2 are configured for these two zones. Before the appliance forwards a packet from Z1, natrule-1 translates the last octet of the packet's source IP address to 100. Similarly, for packets from Z2, natrule-2 translates the last octet of the source IP address to 200. For two clients, CL1-Z1 in zone Z1 and CL1-Z2 in zone Z2, each with IP address 192.0.2.30, the Citrix ADC appliance translates the source IP address of CL1-Z1's packets to 100.0.2.30 and of CL1-Z2's packets to 200.0.2.30. The optimization device to which the Citrix ADC appliance sends the translated packets is configured to use a packet's source IP address to recognize the zone, so it applies the appropriate optimization configured for the zone from which the packet originated.

Configuration Steps

Configuring IP prefix NAT consists of the following steps:

- **Create a net profile and set the NAT Rule parameter of a net profile**. A NAT rule specifies two IP addresses and a net mask. The first IP address (specified by IP Address parameter) is the source IP address that is to be translated with the second one (specified by IP Rewrite parameter). The net mask specifies the part of the source IP address that is to be translated with the same part of the second IP address.
- **Bind the net profile to load balancing virtual servers or services**. A net profile with NAT rule setting can be bound to a virtual server or service of type ANY, UDP, DNS, TCP, and HTTP. After binding a net profile to a virtual server or service, the Citrix ADC appliance matches the source IP address of the incoming packets related to the virtual server or service with the NAT rule setting. The Citrix ADC then performs IP prefix NAT for packets that match the NAT rule.

To configure IP prefix NAT translation by using the command line:

At the command prompt, type:

- **bind netProfile** <name> (-**natRule** <ip_addr> <netmask> <rewriteIp>)
- **show netprofile** <name>

To configure IP prefix NAT by using the GUI:

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Set the following parameters under NAT Rules while adding or modifying NetProfiles.
    - IP Address
    - Netmask

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Rewrite IP

Sample configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has IP prefix NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the Citrix ADC appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the Citrix ADC appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
> add netprofile PARTIAL-NAT-1
Done

> bind netprofile PARTIAL-NAT-1 –natrule 192.0.0.0 255.0.0.0 100.0.0.0
Done

> add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
Done
```

Static ARP

September 14, 2021

You can add static ARP entries to and remove static ARP entries from the ARP table. After adding an entry, you should verify the configuration. If the IP address, port, or MAC address changes after you create a static ARP entry, you must remove or manually adjust the static entry. Therefore, creating static ARP entries is not recommended unless necessary.

To add a static ARP entry by using the CLI:

At the command prompt, type:

- **add arp -IPAddress** <ip_addr> -**mac**<mac_addr> -**ifnum** <interface_name>
- **show arp** <IPAddress>

Example:

```
> add arp -ip 10.102.29.6 -mac 00:24:e8:73:ca:ec -ifnum 1/1
 Done
```

To remove a static ARP entry by using the CLI:

At the command prompt, type the **rm arp** command and the IP address.

To add a static ARP entry by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Navigate to **System** > **Network** > **ARP Table**, and add a static ARP entry.

Specify a VLAN in a Static ARP Entry

In a static ARP entry, you can specify the VLAN through which the destination device is accessible. This feature is useful when the interface specified in the static ARP entry is part of multiple tagged VLANs and the destination is accessible through one of the VLANs. The Citrix ADC appliance includes the specified VLAN ID in the outgoing packets matching the static ARP entry. If you don't specify a VLAN ID in an ARP entry, and the specified interface is part of multiple tagged VLANs, the appliance assigns the interface's native VLAN to the ARP entry.

For example, say Citrix ADC interface 1/2 is part of native VLAN 2 and of tagged VLANs 3 and 4, and you add a static ARP entry for network device A, which is part of VLAN 3 and is accessible through interface 1/2. You must specify VLAN 3 in the ARP entry for network device A. The Citrix ADC appliance then includes tagged VLAN 3 in all the packets destined to network device A, and sends them from interface 1/2.

If you don't specify a VLAN ID, the Citrix ADC appliance assigns native VLAN 2 for the ARP entry. Packets destined to device A are dropped in the network path, because they do not specify tagged VLAN 3, which is the VLAN for device A.

To specify a VLAN in a static ARP entry by using the CLI:

At the command prompt, type:

- **add arp -IPAddress** <ip_addr> **-mac**<mac_addr> **-ifnum** <interface_name> [-**vlan** <positive_integer>]
- **show arp** <IPAddress>

Example:

```
1 > add arp -ip 198.51.100.91 -mac 36:db:4b:f6:12:15 -ifnum 1/2 -vlan 3
2 Done
```

Set the Timeout for Dynamic ARP Entries

September 14, 2021

You can globally set an aging time (time-out value) for dynamically learned ARP entries. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing ARP entries expire after the previously configured aging time. You can specify an ARP time-out value of from 1 through 1200 seconds.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set the time-out for dynamic ARP entries by using the CLI:

At the command prompt, type:

- **set arpparam** -**timeout** <positive_integer>]
- **show arpparam**

Example:

```
> set arpparam -timeout 500
 Done
```

To set the time-out for dynamic ARP entries to its default value by using the CLI:

At the command prompt, type:

- **unset arpparam**
- **show arpparam**

Example:

```
> unset arpparam
 Done
```

To set the time-out for dynamic ARP entries by using the GUI:

Navigate to **System** > **Network**, in the **Settings** group, click **Configure ARP Global Parameters**, and set the **ARP Table Entry Timeout** parameter.

Neighbor Discovery

September 14, 2021

Neighbor discovery (ND) is one of the most important protocols of IPv6. It is a message-based protocol that combines the functionality of the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Router Discovery. ND allows nodes to advertise their link layer addresses and obtain the MAC addresses or link layer addresses of the neighboring nodes. This process is performed by the Neighbor Discovery protocol (ND6).

Neighbor discovery can perform the following functions:

- **Router Discovery**: Enables a host to discover the local routers on an attached link and automatically configure a default router.
- **Prefix Discovery**: Enables the host to discover the network prefixes for local destinations.

  Note: The Citrix ADC appliance does not support Prefix Discovery.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Parameter Discovery**: Enables a host to discover additional operating parameters, such as MTU and the default hop limit for outbound traffic.
- **Address Autoconfiguration**: Enables hosts to automatically configure IP addresses for interfaces both with and without stateful address configuration services such as DHCPv6. The Citrix ADC does not support Address Autoconfiguration for Global IPv6 addresses.
- **Address Resolution**: Equivalent to ARP in IPv4, enables a node to resolve a neighboring node's IPv6 address to its link-layer address.
- **Neighbor Unreachability Detection**: Enables a node to determine the reachability state of a neighbor.
- **Duplicate Address Detection**: Enables a node to determine whether an NSIP address is already in use by a neighboring node.
- **Redirect**: Equivalent to the IPv4 ICMP Redirect message, enables a router to redirect the host to a better first-hop IPv6 address to reach a destination.

Note: The Citrix ADC appliance does not support IPv6 Redirect.

Configuration Steps

Configuring neighbor discovery consists of the following tasks:

- Adding IPv6 neighbors
- (Optional) Removing IPv6 neighbors

CLI procedures

To add an IPv6 neighbor by using the CLI:

At the command prompt, type:

- **add nd6** <neighbor> <mac> <ifnum> [-**vlan** <integer>]
- **sh nd6**

Example:

```
1 > add nd6 2001::1 00:04:23:be:3c:06 1/1 –vlan 1
2  Done
3
4 > show nd6
5    Neighbor                 MAC-Address(Vlan, Interface)       State
               TIME
6    --------                 ---------------------------       -----
             --------
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
1) ::1                      00:d0:68:0b:58:da(   1,  LO/1)   REACHABLE
        PERMANENT
2) fe80::2d0:68ff:fe0b:58da 00:d0:68:0b:58:da(   1,  LO/1)   REACHABLE
        PERMANENT
3) 2001::1                  00:04:23:be:3c:06(   1,   1/1)   REACHABLE
         STATIC
 Done
```

To remove a neighbor discovery entry by using the CLI:

At the command prompt, type:

- **rm nd6** <Neighbor> -**vlan** <VLANID>

Example:

```
rm nd6 3ffe:100:100::1 -vlan 1
```

To remove all neighbor discovery entries by using the CLI:

At the command prompt, type:

- **clear nd6**

GUI procedures

To add an IPv6 neighbor by using the GUI:

Navigate to **System** > **Network** > **IPv6 Neighbors**, and add a new IPv6 neighbor.

To remove a neighbor discovery entry by using the GUI:

Navigate to **System** > **Network** > **IPv6 Neighbors**, delete the IPv6 neighbor.

To remove all neighbor discovery entries by using the GUI:

Navigate to **System** > **Network** > **IPv6 Neighbors**, and click **Clear**.

IP Tunnels

February 21, 2023

An IP Tunnel is a communication channel, that can be created by using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent via the tunnel.

The Citrix ADC appliance implements IP Tunneling in the following ways:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Citrix ADC as an Encapsulator (Load Balancing with DSR Mode)**: Consider an organization that has multiple data centers across different countries, where the Citrix ADC maybe at one location and the back-end servers are located in a different country. In essence, the Citrix ADC and the back-end servers are on different networks and are connected via a router.

  When you configure Direct Server Return (DSR) on this Citrix ADC, the packet sent from the source subnet is encapsulated by the Citrix ADC and sent via a router and tunnel to the appropriate back-end server. The back-end server decapsulates the packet and responds directly to the client, without allowing the packet to pass via the Citrix ADC.

- **Citrix ADC as a Decapsulator:** Consider an organization having multiple data centers each having Citrix ADCs and back-end servers. When a packet is sent from data center A to data center B it is usually sent via an intermediary, say a router or another Citrix ADC. The Citrix ADC processes the packet and then forwards the packet to the back-end server. However, if an encapsulated packet is sent, the Citrix ADC must be able to decapsulate the packet before sending it to the back-end servers. To enable the Citrix ADC to function as a decapsulator, a tunnel is added between the router and the Citrix ADC. When the encapsulated packet, with additional header information, reaches the Citrix ADC, the data packet is decapsulated i.e. the additional header information is removed, and the packet is then forwarded to the appropriate back-end servers.

  The Citrix ADC can also be used as a decapsulator for the Load Balancing feature, specifically in scenarios when the number of connections on a vserver exceeds a threshold value and all the new connections are then diverted to a back-up vserver.

The IP Tunnel feature is available with a Citrix ADC Premium edition license. For more information about Citrix ADC edition licenses and Citrix ADC features matrix, see Citrix ADC Editions data sheet.

Configure IP Tunnels

Configuring IP tunnels on a Citrix ADC appliance consists of creating IP tunnel entities. An IP tunnel entity specifies the local and remote tunnel end-point IP addresses and the protocol to be used for the IP tunnel.

Note: While configuring an IP tunnel in a cluster setup, the local IP address must be a striped SNIP address.

CLI procedures

To create an IP tunnel by using the CLI:

At the command prompt type:

- **add iptunnel** <name> <remote> <remoteSubnetMask> <local> -**type** -**protocol** (**ipoverip** | **GRE**)

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **show iptunnel**

To remove an IP tunnel by using the CLI:

To remove an IP tunnel, type the **rm iptunnel** command and the name of the tunnel.

To create an IPv6 tunnel by using the CLI:

At the command prompt type:

- **add ip6tunnel** <name> <remoteIp> <local>
- **show ip6tunnel**

To remove an IPv6 tunnel by using the CLI:

To remove an IPv6 tunnel, type the **rm ip6tunnel** command and the name of the tunnel.

GUI procedures

To create an IP Tunnel by using the GUI:

Navigate to **System** > **Network** > **IP Tunnels**, add a new IP tunnel.

To create an IPv6 Tunnel by using the GUI:

Navigate to **System** > **Network** > **IP Tunnels** > **IPv6 Tunnels**, and add a new IPv6 tunnel.

Customizing IP Tunnels Globally

By globally specifying the source IP address, you can assign a common source IP address across all tunnels. Also, because fragmentation is CPU-intensive, you can globally specify that the Citrix ADC appliance drop any packet that requires fragmentation. Alternatively, if you would like to fragment all packets as long as a CPU threshold value is not reached, you can globally specify the CPU threshold value.

CLI procedures

To globally customize IP tunnels by using the CLI:

At the command prompt, type:

- **set ipTunnelParam** -**srcIP** <sourceIPAddress> -**srcIPRoundRobin** (**YES** | **NO**)-**dropFrag** [**YES** | **NO**] -**dropFragCpuThreshold** <Positive integer>
- **show ipTunnelParam**

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> set iptunnelparam –srcIP 12.12.12.22 -dropFrag Yes –
   dropFragCpuThreshold 50
 Done

> set iptunnelparam -srcIPRoundRobin YES -dropFrag Yes –
   dropFragCpuThreshold 50
 Done
```

To globally customize IPv6 tunnels by using the CLI:

At the command prompt, type:

- **set ip6tunnelparam** -**srcIP** <IPv6Address> -**srcIPRoundRobin** (**YES** | NO)-**dropFrag** [**YES** | **NO**] -**dropFragCpuThreshold** <Positive integer>
- **show ip6tunnelparam**

GUI procedures

To globally customize IP tunnels by using the GUI:

Navigate to **System** > **Network**, in the Settings group, click **IPv4 Tunnel Global Settings**.

1. Navigate to **System** > **Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

To globally customize IPv6 tunnels by using the GUI:

1. Navigate to **System** > **Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

GRE Payload Options in a GRE IP Tunnel

For a configured GRE IP tunnel, the Citrix ADC appliance encapsulates the entire Layer 2 packet, including the Ethernet header and the VLAN header (dot1q VLAN tag). IP GRE tunnels between Citrix ADC appliances and some 3rd party devices might not be stable, because these 3rd party devices are not programmed to process some or the Layer 2 packet headers. To configure a stable IP GRE tunnel between a Citrix ADC appliance and a 3rd party device, you can use the GRE payload parameter of the GRE IP tunnel command set. GRE payload setting can also be applied to a GRE with IPSec tunnel.

You can set the GRE payload parameter to do one of the following before the packet is sent through the GRE tunnel:

- **Ethernet with DOT1Q**. Carry the Ethernet header as well the VLAN header. This is the default setting. For a tunnel bound to a netbridge, inner Ethernet header and VLAN header contains

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

information from the ARP and bridge table of the Citrix ADC appliance. For a tunnel set as a next hop to a PBR rule, Inner Ethernet destination MAC address is set to zero and the VLAN header specifies the default VLAN. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

Outer Ethernet Header	Outer IP Header	GRE Header	Inner Ethernet	Inner VLAN header	Inner IP/IPv6/ARP header	Inner TCP/UDP Header	Payload

- **Ethernet**. Carry the Ethernet header but drop the VLAN header. Because the packets do not carry any VLAN information in the tunnel, for a tunnel with this setting and bound to a netbridge, you must bind an appropriate VLAN to the netbridge so that on receiving any packets on the tunnel, the Citrix ADC can forward these packet to the specified VLAN. If the tunnel is set as a next hop in a PBR rule, the Citrix ADC routes the packets that are received on the tunnel. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

Outer Ethernet header	Outer IP header	GRE Header	Inner Ethernet header	Inner IP/IPv6/ARP header	Inner TCP/UDP header	Payload

- **IP**. Drop the Ethernet header as well as the VLAN header. Because tunnels with this setting do not carry Layer 2 headers, these tunnels cannot be bound to a netbridge but can be set as a next hop in a PBR rule. The peer tunnel endpoint device on receiving the packet either consumes or routes it. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

Outer Ethernet header	Outer IP header	GRE header	Inner IP/IPv6 header	Inner TCP/UDP header	Payload

To drop Layer 2 headers of packets in a GRE IP tunnel by using the CLI:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> [-**protocol** <GRE> [-**vlan** <positive_integer>]] [-**grepayload** <grepayload>] [-**ipsecProfileName** <string>]
- **show iptunnel** <tunnelname>

Example:

```
1 > add iptunnel IPTUNNEL-1 203.0.113.133 255.255.255.0 198.51.100.15 –
    protocol GRE –grepayload Ethernet -ipsecProfileName IPTUNNEL-IPSEC
    -1
2 Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

IPv6 Traffic through GRE IPV4 Tunnels

The Citrix ADC appliance supports transferring IPv6 traffic through an IPV4 GRE tunnel. This feature can be used for enabling communication between Isolated IPv6 networks without upgrading the IPv4 infrastructure between them.

For configuring this feature, you associate a PBR6 rule with the configured IPv4 GRE tunnel through which you want the Citrix ADC to send and receive IPv6 traffic. The source IPv6 address and destination IPv6 address parameters of the PBR6 rule specify the IPv6 networks whose traffic is to traverse the IPv4 GRE tunnel.

Note: IPSec protocol is not supported on GRE IPv4 tunnels that are configured to transfer IPv6 packets.

To create a GRE IPv4 tunnel by using the CLI:

At the command prompt, type:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> -**protocol GRE**
- **show ipTunnel** <name>

To associate a PBR6 rule with a GRE IPv4 tunnel by using the CLI:

- **add ns pbr6** <pbrName> **ALLOW** -**srcIPv6** <network-range> -**dstIPv6** <network-range> -**ipTunnel** <tunnelName>
- **show pbr**

Sample configuration

In the following sample configuration, GRE IP tunnel TUNNEL-V6onV4 is created with remote tunnel endpoint IP address 10.10.6.30 and local tunnel endpoint IP address 10.10.5.30. The tunnel is then bound to pbr6 PBR6-V6onV4. The srcIPv6 specifies the IPv6 network connected to the local endpoint and destIPv6 specifies the IPv6 network connected to the remote endpoint. The traffic from these Ipv6 networks are allowed to traverse through the GRE IPv4 tunnel.

```
1 > add ipTunnel TUNNEL-V6onV4 10.10.6.30 255.255.255.255 10.10.5.30 -
     protocol GRE
2 -ipsecProfileName None
3 Done
4 > add ns pbr6 PBR6-V6onV4 ALLOW -srcIPv6 = 2001:0db8:1::1-2001:0db8
     :1::255 -destIPv6 =
5 1-2001:0db8:4::255 -ipTunnel TUNNEL-V6onV4
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Send Response Traffic Through an IP-IP Tunnel

You can configure a Citrix ADC appliance to send response traffic through an IP-IP tunnel instead of routing it back to the source. By default, when the appliance receives a request from another Citrix ADC or a third-party device through an IP-IP tunnel, it routes the response traffic instead of sending it through the tunnel. You can use policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) to send the response through the tunnel.

In a PBR rule, specify the subnets at both end points whose traffic is to traverse the tunnel. Also set the next hop as the tunnel name. When response traffic matches the PBR rule, the Citrix ADC appliance sends the traffic through the tunnel.

Alternatively, you can enable MBF to meet this requirement, but the functionality is limited to traffic for which the Citrix ADC appliance stores session information (for example, traffic related to load balancing or RNAT configurations). The appliance uses the session information to send the response traffic through the tunnel.

CLI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the CLI:

At the command prompt, type:

- **add ns pbr** <pbr_name> **ALLOW** -**srcIP** = <local_subnet_range> -**destIP** = <remote_subnet_range> -**ipTunnel** <tunnel_name>
- **apply ns pbrs**
- **show ns pbr** <pbr_name>

To enable MAC-based forwarding by using the CLI:

At the command prompt, type:

- **enable ns mode MBF**
- **show ns mode**

GUI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the GUI:

1. Navigate to **System** > **Network** > **PBRs**. On the **PBRs** tab, create a **PBR** rule.
2. While creating the PBR, set the **Next Hop Type** to **IP tunnel** and **IP Tunnel Name** to the configured IP-IP tunnel name.

To enable MAC-based forwarding by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Navigate to **System** > **Settings**, in **Modes and Features**, click **Configure Modes**.
2. On the **Configure Modes** page, select **MAC-based forwarding**.

Sample configuation

Consider an example of an IPIP tunnel, NS1-NS2-IPIP, which is set up between two Citrix ADC appliances NS1 and NS2.

By default, for any request that NS2 receives through the tunnel, its routes the response traffic to the source instead of sending it (to NS1) through the tunnel.

You can configure policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) on NS2 for enabling it to send the response through the tunnel.

In the following sample configuration on NS2, NS1-NS2-IPIP is an IPIP tunnel and NS1-NS2-IPIP-PBR is a PBR rule. For requests (with inner source IP address in the range 10.102.147.0-10.102.147.255 and inner destination IP address in the range 10.102.147.0-10.102.147.255) received by NS2 through the tunnel, NS2 sends the corresponding response through the tunnel (to NS1) instead of routing it to the source. The functionality is limited to the traffic that matches the PBR rule.

```
> add iptunnel NS1-NS2-IPIP 192.0.2.99 255.255.255.255 203.0.113.99 -
    protocol IPIP

Done
> add pbr NS1-NS2-IPIP-PBR -srcIP 10.102.147.0-10.102.147.255  - destIP
    10.20.1.0-10.20.1.255  - ipTunnel NS1-NS2-IPIP

Done
> apply pbrs

Done
```

Alternatively, MBF can be enabled on NS2. The functionality is limited to traffic for which NS2 stores session information (for example, traffic related to load balancing or RNAT configurations).

```
> enable ns mode MBF

Done
```

Class E IPv4 packets

September 14, 2021

By default, the Citrix ADC appliance drops any packets if they contain any class E IPv4 address in the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

source IP or the destination IP fields. If your setup is using class E IPv4 addresses, you can configure the Citrix ADC appliance to process class E IPv4 packets.

Before you begin

Before you begin configuring a Citrix ADC appliance to process class E IPv4 packets, note the following points:

- Citrix ADC appliances do not support configuring any Citrix ADC owned IPv4 address (for example, SNIP and VIP) in the class E range. Citrix ADC appliances only support processing of class E IPv4 packets.
- A Citrix ADC appliance internally uses class E IPv4 addresses for the IPv6 feature. The Citrix ADC appliance does not support both features (processing class E IPv4 packets and IPv6 support) working at the same time. The Citrix ADC appliance imposes a restriction to not enable the IPv6 feature when processing of class E IPv4 packets is enabled, and vice versa.

Configuration steps

Configuring a Citrix ADC appliance to process class E IPv4 packets consist of the task of enabling the **IPv4 Class E address clients** (**allowClassEIPv4**) Layer 3 parameter.

CLI procedures

To configure the Citrix ADC appliance to process Class E IPv4 packets by using the CLI:

At the command prompt, type:

set l3param -**allowClassEIPv4** (**ENABLED** **DISABLED**)

-
- **show l3param**

Sample Configuration:

```
> set l3param –allowClassEIPv4 ENABLED

Done

> sh l3param

    Network L3 related Configuration Parameters
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```

9      icmpgen_rate_threshold      : 100
10
11     srcnat                      : ENABLED
12
13     override_rnat               : DISABLED
14
15     drop_df_flag                : DISABLED
16
17     .
18
19     .
20
21     .
22
23     IPv6DynamicRouting          : DISABLED
24
25     allowClassEIPv4             : ENABLED
26
27 Done
```

GUI procedures

To configure the Citrix ADC appliance to process Class E IPv4 packets by using the GUI:

1. Navigate to **System** > **Network**, and then in the **Settings** section, click **Configure Layer 3 Parameters**.
2. Select **IPv4 Class E address clients** and click **OK**.

Interfaces

September 14, 2021

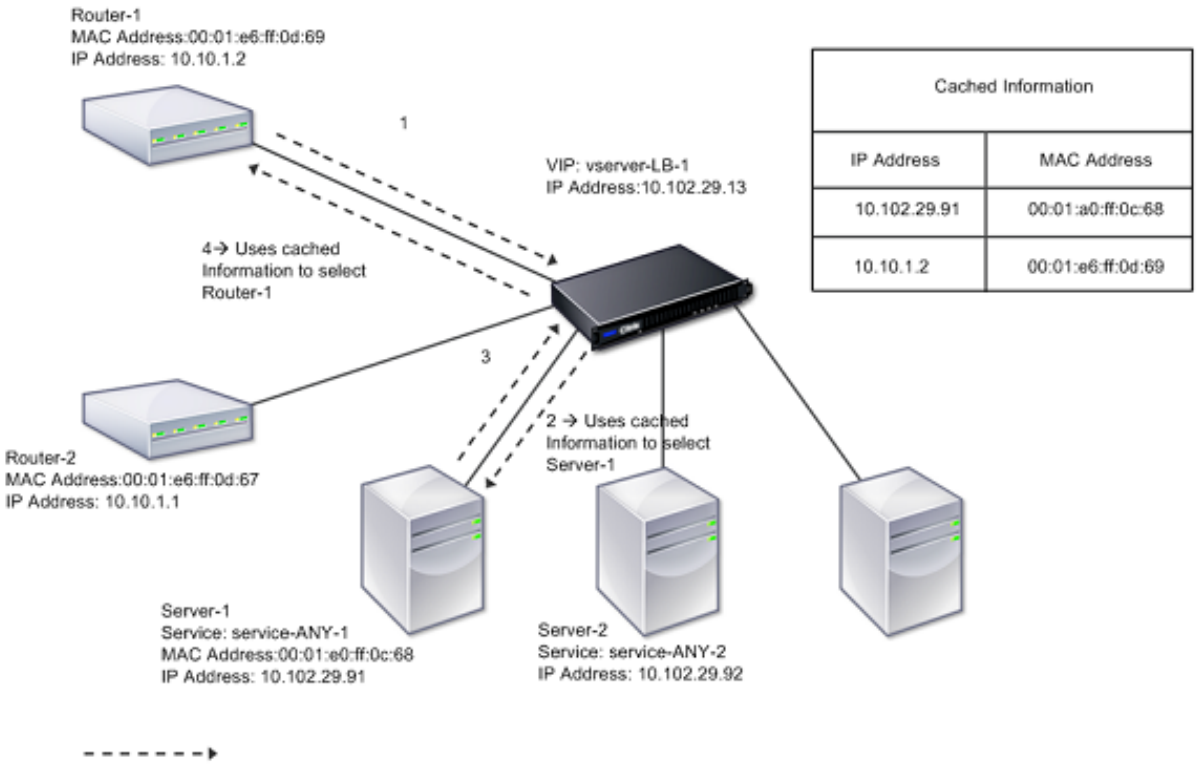
Before you begin configuring interfaces, decide whether your configuration can use MAC-based forwarding mode, and either enable or disable this system setting accordingly. The number of interfaces in your configuration is different for the different models of the Citrix ADC appliance. In addition to configuring individual interfaces, you can logically group interfaces, using VLANs to restrict data flow within a set of interfaces, and you can aggregate links into channels. In a high availability setup, you can configure a virtual MAC address if necessary. If you use L2 mode, you might want to modify the aging of the bridge table.

When your configuration is complete, decide whether you should enable the system setting for path MTU discovery. Citrix ADC appliances can be deployed in active-active mode using VRRP. An active-active deployment, in addition to preventing downtime, makes efficient use of all the Citrix ADC appli-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

ances in the deployment. You can use the Network Visualizer tool to view the network configuration of a Citrix ADC deployment and configure interfaces, channels, VLANs, and bridge groups.

Configuring MAC-Based Forwarding



September 14, 2021

With MAC-based forwarding (MBF) enabled, when a request reaches the Citrix ADC appliance, the appliance remembers the source MAC address of the frame and uses it as the destination MAC address for the resulting replies. MAC-based forwarding can be used to avoid multiple-route/ARP lookups and to avoid asymmetrical packet flows. MAC-based forwarding may be required when the Citrix ADC is connected to multiple stateful devices, such as VPNs or firewalls, because it ensures that the return traffic is sent to the same device that the initial traffic came from.

MAC-based forwarding is useful when you use VPN devices, because it guarantees that all traffic flowing through a VPN passes back through the same VPN device.

The following topology diagram illustrates the process of MAC-based forwarding.

Figure 1. MAC-Based Forwarding Mode

When MAC-based forwarding (MBF) is enabled, the Citrix ADC caches the MAC address of:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server replies through the Citrix ADC appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when the Citrix ADC initiates a connection, it uses the route and ARP tables for the lookup function. In a direct server return configuration, you must enable MAC-based forwarding.

For more information about direct server return configurations, see Load Balancing.

Some deployment topologies may require the incoming and outgoing paths to flow through different routers. MAC-based forwarding would break this topology design.

MBF should be disabled in the following situations:

- **When a server uses network interface card (NIC) teaming without using LACP (802.1ad Link Aggregation).** To enable MAC-based forwarding in this situation, you must use a layer 3 device between the Citrix ADC and server.
  Note: MBF can be enabled when the server uses NIC teaming with LACP, because the virtual interface uses one MAC address.
- **When firewall clustering is used**. Firewall clustering assumes that ARP is used to resolve the MAC address for inbound traffic. Sometimes the inbound MAC address can be a non-clustered MAC address and should not be used for inbound packet processing.

When MBF is disabled, the appliance uses L2 or L3 connectivity to forward the responses from servers to the clients. Depending on the route table, the routers used for outgoing connection and incoming connection can be different. In the case of reverse traffic (response from the server):

- If the source and destination are on different IP subnets, the appliance uses the route lookup to locate the destination.
- If the source is on the same subnet as the destination, the Citrix ADC looks up the ARP table to locate the network interface and forwards the traffic to it. If the ARP table does not exist, the Citrix ADC requests the ARP entries.

To enable or disable MAC-based forwarding by using the CLI:

At the command prompt, type:

- **enable ns mode MBF**
- **disable ns mode MBF**

To enable or disable MAC-based forwarding by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Navigate to **System** > **Settings**, in the **Modes and Features** group, click **Configure modes**.
2. Select or clear the **MAC-based forwarding** option.

MAC based forwarding for a load balancing setup

Some load balancing setups require that the Citrix ADC appliance bypasses the global MBF (if enabled) for these setups and instead use the route/ARP lookups for sending packets to the destination.

The MBF parameter of a net profile is used to enable or disable MBF for a specific load balancing configuration. MBF can be set for the client side as well as the server side of a load balancing configuration by binding net profiles (MBF enabled or disabled) to the virtual server and the services.

For example, if a net profile with MBF disabled is bound to the virtual server of a load balancing configuration, the Citrix ADC appliance bypasses the global MBF (if enabled) and instead use the route/ARP lookups for sending response packets to clients.

Before you begin

Before you begin configuring MBF for a load balancing configuration, note the following points:

- In a load balancing configuration, the client side (virtual server) and the server side (service/service groups) can have different MBF settings.
- A load balancing configuration inherits global MBF setting if MBF is not set explicitly in the net profiles bound to the virtual server and the services.
- In a load balancing configuration, server side (service) inherits client side MBF setting of net profile bound to the virtual server if no net profile is bound to the service.
- In a load balancing configuration with direct server return mode, client side inherits the MBF setting in the net profile bound to the service.
- In a content switching configuration, client side takes the MBF setting in the net profile bound to the content switching virtual server instead of from the target load balancing virtual server.

Limitations

Before you begin configuring MBF for a load balancing configuration, note the following limitations:

- MBF setting for load balancing configurations is not supported in a cluster setup.
- For a load balancing virtual server with MAC mode or L2Conn settings, MBF is enabled irrespective of the MBF setting in the bound net profile to the virtual server.
- The Citrix ADC appliance does not support setting MBF for load balancing monitors using net profile. In other words, the MBF setting of a net profile is not applied to the monitors to which the net profile is bound. The global MBF setting is applied to monitors irrespective of the MBF setting of the bound net profile.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure MBF for load balancing configuration

Configuring MBF for a load balancing configuration consists of the following tasks:

- Enable MBF parameter in a net profile.
- Bind the net profile to a load balancing virtual server or services.

To enable MBF in a net profile by using the CLI:

- To enable MBF while adding a net profile, at the command prompt, type:
  - **add netProfile** <name> -**MBF** (**ENABLED** | **DISABLED**)
  - **show netprofile** <name>
- To enable MBF in an existing net profile, at the command prompt, type:
  - **set netProfile** <name> -**MBF** (**ENABLED** | **DISABLED**)
  - **show netprofile** <name>

To enable MBF in a net profile by using GUI**

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Enable the **MBF** parameter while adding or modifying a net profile.

In the following sample configuration, net profile NETPROFILE-MBF-LBVS has MBF enabled and is bound to load balancing virtual server LBVS-1. Also, net profile NETPROFILE-MBF-SVC has MBF enabled and is bound to a load balancing service SVC-1.

```
> add netprofile NETPROFILE-MBF-LBVS -MBF ENABLED

Done

> add netprofile NETPROFILE-MBF-SVC -MBF ENABLED

Done

> set lb vserver LBVS-1 -netprofile NETPROFILE-MBF-LBVS

Done

> set service SVC-1 -netprofile NETPROFILE-MBF-SVC

Done
```

Configure network interfaces

November 7, 2023

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Network interfaces in the Citrix ADC appliance are numbered in <slot><port> notation. After configuring your interfaces, display the interfaces and their settings to verify the configuration. You can also display this information to troubleshoot a problem in the configuration.

To manage the network interfaces, you can do the following;

- Enable some interfaces and disable others.
- Reset an interface to renegotiate its settings.
- Clear the accumulated statistics for an interface.

To verify the configuration, you can display the interface settings. You can display the statistics for an interface to evaluate its health.

Set the network interface parameters

The network interface configuration is neither synchronized nor propagated. For an HA pair, you must perform the configuration on each unit independently.

> **Note:**
>
> In an HA setup, if the `tag all` parameter is enabled, then the HA packets are also tagged with the VLAN traffic. However, there might be issues with the high availability communication. Therefore, it is recommended to configure NSVLAN or HA SYNC VLAN for HA traffic.
>
> - For NSVLAN configuration, see Configuring NSVLAN.
> - For HA SYNC VLAN configuration, see Configure HA SYNC VLAN.

To set the network interface parameters by using the CLI:

At the command prompt, type:

```
1 -  set interface <id> [-speed <speed>] [-duplex <duplex>] [-flowControl
      <flowControl>] [-autoneg ( DISABLED | ENABLED )] [-haMonitor ( ON |
      OFF )] [ ( ON | OFF )] [-tagall ( ON | OFF )] [-lacpMode <lacpMode
     >] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>]
     [-lacpTimeout (LONG | SHORT )] [-ifAlias <string>] [-throughput <
     positive_integer>][-bandwidthHigh <positive_integer> [-
     bandwidthNormal <positive_integer>]]
2 -  show interface [<id>]
```

Example:

```
1 > set interface 1/8 -duplex full
2  Done
```

To set the network interface parameters by using the GUI:

Navigate to **System > Network > Interfaces**, select the network interface that you want to modify (for example, 1/8), click **Edit**, and then set the parameters.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Setting the receive ring size and ring type for an interface

You can increase the receive ring size and ring type for IX, F1X, F2X, or F4X interfaces on Citrix ADC MPX and SDX platforms.

An increased ring size provides more cushion to handle burst traffic, but might impact the performance. A ring size of up to 8192 is supported for IX interfaces. A ring size of up to 4096 is supported for F1X, F2X, and F4X interfaces. The default ring size remains 2048.

Interface ring types are elastic by default. They increase or decrease in size based on packet arrival rate. You can configure the ring type as "fixed"in which case the ring size does not change based on traffic rate.

Note: This feature is supported from release 13.0 build 41.x, and supported on platforms that have IX, F1X, F2X, or F4X interfaces.

Use the `show hardware` command to identify whether your appliance has IX, F1X, F2X, or F4X interfaces.

Examples:

The following model has 16 F1X (10G) interfaces and 4 F4X (40G) interfaces.

```
1  > sh hardware
2          Platform: NSMPX-25000-40G 20*CPU+16*F1X+4*F4X+2*E1K+2*CVM N3
               250040
3          Manufactured on: 12/16/2016
4          CPU: 2800MHZ
5          Host Id: 234913926
6          Serial no: N43RJCRV3X
7          Encoded serial no: N43RJCRV3X
8          Netscaler UUID: 336a32d6-2cfa-11e8-bf01-00e0ed5dd23c
9          BMC Revision: 4.08
10  Done
```

The following model has 2 1X (10G) interfaces.

```
1  > sh hardware
2          Platform: NSMPX-10500 8*CPU+2*E1K+8*E1K+2*IX+8*CVM 1620 760100
3          Manufactured on: 12/27/2010
4          CPU: 2832MHZ
5          Host Id: 1707114630
6          Serial no: 7VZZV1ZXJ4
7          Encoded serial no: 7VZZV1ZXJ4
8          Netscaler UUID: eb1bfd72-5176-11e7-ba18-00e0ed1b0d12
9   Done
```

To configure ring size and ring type by using the CLI
At the command line, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set interface <id> -ringsize <positive_integer> -ringtype ( Elastic |
    Fixed )
```

Parameters:

ringsize:

The receive ring size of the interface. A higher number provides more buffers to handle incoming traffic.

Default value: 2048
Minimum value: 512
Maximum value: 16384

ringtype:

The receive ring type of the interface. A fixed ring type preallocates the configured number of buffers irrespective of traffic rate. In contrast, an elastic ring, expands and shrinks based on incoming traffic rate.

Possible values: Elastic, Fixed

Default value: Elastic

Example:

```
> set interface 40/2 -ringsize 4096 -ringtype Fixed
 Done
> show interface 40/2

1)      Interface 40/2 (40G Ethernet, CR4, 40 Gbit) #21  flags=0xc020 <
    ENABLED, UP, UP, autoneg, HAMON, HEARTBEAT, 802.1q> MTU=1500, native
     vlan=10, MAC=00:e0:ed:75:14:2a, uptime 119h26m32s
        Requested: media AUTO, speed AUTO, duplex AUTO, fctl OFF,
            throughput 0
        Actual: media UTP, speed 40000, duplex FULL, fctl OFF,
            throughput 40000
        LLDP Mode: NONE, LR Priority: 1024
        RX: Pkts(1443972660032) Bytes(1457207315336105) Errs(0) Drops
            (53319) Stalls(0)
        TX: Pkts(1452311431262) Bytes(1458534011197761) Errs(0) Drops
            (788) Stalls(0)
        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
        Bandwidth thresholds are not set.
        Rx Ring: Configured size=4096, Actual size=4096, Type: Fixed
 Done
```

The last line shows the configured and actual ring size, and the ring type.

To configure ring size and ring type by using the GUI:

1. Navigate to **System > Network > Interfaces**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. Select your interface and click **Edit**.
3. In **Ring Size**, specify one of the following:
   - **IX interfaces:** 512, 1024, 2048, 4096, or 8192.
   - **F1X, F2X, or F4X interfaces:** 512, 1024, 2048, or 4096.
4. In **Ring Type**, select Elastic or Fixed.
5. Click **OK**.

Enable and disable network interfaces

By default, the network interfaces are enabled. Disable any network interface that is not connected to the network, so that it cannot send or receive packets. Disabling a network interface that is connected to the network in a high availability setup can cause a failover.

For more information about high availability, see High Availability.

To enable or disable a network interface by using the CLI:

At the command prompt, type:

```
-  enable interface <interface_num>
-  show interface <interface_num>
-  disable interface <interface_num>
-  show interface <interface_num>
```

Example:

```
> enable interface 1/8
 Done
> show interface 1/8
        Interface 1/8 (Gig Ethernet 10/100/1000 MBits) #2
        flags=0x4004000 <ENABLED, DOWN, BOUND to LA/1, down, autoneg,
           802.1q>
        MTU=1514, MAC=00:d0:68:15:fd:3d, downtime 906h58m40s
        Requested: media UTP, speed AUTO, duplex FULL, fctl OFF,
           throughput 0
        RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
        TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
        Bandwidth thresholds are not set.
Done
```

To enable or disable a network interface by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select Enable or Disable.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Reset network interfaces

Network interface settings control properties such as duplex and speed. To renegotiate the settings of a network interface, you must reset it.

To reset a network interface by using the CLI:

At the command prompt, type:

```
- reset interface <interface_num>
- show interface <interface_num>
```

Example:

```
> reset interface 1/8
 Done
```

To reset a network interface by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select **Reset Interface**.

Monitor a network interface

You can display network interface statistics to monitor parameters and use the information to check the health of the network interface. You can monitor parameters, such as packets sent and packets received, throughput, Link Aggregate Control Protocol (LACP) data units, and errors. You can clear the statistics of a network interface to monitor its statistics from the time the statistics are cleared.

To display the statistics of the network interfaces by using the CLI:

At the command prompt, type:

```
- stat interface <interface_num>
```

Example:

```
> stat interface 1/8
 Done
```

To clear a network interface's statistics by using the CLI:

At the command prompt, type:

```
- clear interface <interface_num>
```

Example:

```
> clear interface 1/8
 Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To display the statistics of an Interface by using the GUI:

Navigate to **System > Network > Interfaces**, select the network interface, and click **Interface Statistics**.

To clear a network interface's statistics by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select **Clear Statistics**.

Configuring Forwarding Session Rules

September 14, 2021

By default, the Citrix ADC appliance does not create session entries for traffic that it only forwards (L3 mode). For a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path, you can create a forwarding-session rule. A forwarding-session rule creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the Citrix ADC. You can create forwarding session rules for IPv4 traffic as well as IPv6 traffic.

When configuring an IPv4 forwarding-session rule, you can specify either an IPv4 network address or an extended ACL as the condition for identifying IPv4 traffic for which to create a forwarding-session entry:

- **Network address**. When you specify an IPv4 network address, the appliance creates forwarding sessions for IPv4 traffic whose source or destination matches the network address.
- **Extended ACL rule**. When you specify an extended ACL rule, the appliance creates forwarding sessions for IPv4 traffic that matches the conditions specified in the extended ACL rule.

When configuring an IPv6 forwarding-session rule, you can specify either an IPv6 prefix or an ACL6 as the condition for identifying IPv6 traffic for which to create a forwarding-session entry:

- **IPv6 prefix**. When you specify an IPv6 prefix, the appliance creates forwarding sessions for IPv6 traffic whose source or destination matches the IPv6 prefix.
- **ACL6 rule**. When you specify an ACL6 rule, the appliance creates forwarding sessions for IPv6 traffic that matches the conditions specified in the ACL6 rule.

To create an IPv4 forwarding session rule by using the CLI:

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- add forwardingSession <name> [<network> <netmask>] | [-aclname <string>] -connfailover (ENABLED | DISABLED)
- show forwardingSession

Example:

```
A network address as the condition:

> add forwardingSession fs-nw-1 10.102.105.51 255.255.255.255
 Done

An ACL as the condition:

> add forwardingSession fs-acl-1 acl1
 Done
```

To configure an IPv4 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv4 forwarding session, or edit an existing forwarding session.

To create an IPv6 forwarding session rule by using the CLI:

- At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:
  - add forwardingSession <name> [<IPv6 prefix>] | [-acl6name <string>]
  - show forwardingSession

  Example:

```
    An IPv6 prefix as the condition:

    > add forwardingSession fsv6-pfx-1 3ffe::/64
     Done

    An ACL6 rule as the condition:

    > add forwardingSession fsv6-acl6-1  –acl6name ACL6-FS
     Done
```

To configure an IPv6 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv6 forwarding session, or edit an existing forwarding session.

Assigning an ACL rule to an Existing Forwarding Session Rule

You can assign an ACL rule to a Network-address/IPv6-prefix based forwarding session rule, in which case it becomes an ACL based forwarding session rule. You can also change an existing ACL rule to

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

another ACL rule in an ACL based forwarding session rule. After the existing related forwarding session entries (if any) have timed out, the rules start using the newly assigned ACL to identify IPv4/IPv6 traffic for which to create a forwarding-session entry.

To assign an extended ACL rule to an existing IPv4 forwarding session rule by using the CLI:

At the command prompt, type

- `set forwardingSession <name> [-aclname <string>]`
- `show forwardingSession <name>`

To assign an ACL6 rule to an existing IPv6 forwarding session rule by using the CLI:

At the command prompt, type

- `set forwardingSession <name> [-acl6name <string>]`
- `show forwardingSession <name>`

Example:

```
1 > add forwardingSession FS-1 -aclname ACL-9
2 Done
3
4 > add forwardingSession FS6-1  – acl6name ACL6-9
5 Done
```

Disabling Steering for Forwarding Sessions on a Cluster Setup

The default behavior of a Citrix ADC cluster is for the node that receives traffic (flow receiver) to direct the traffic to another node (flow processor), which processes the traffic. Directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

Steering can be an overhead for real-time processing or when the setup includes high-latency links.

Steering for forwarding sessions can now be disabled so that the processing becomes local to the flow receiver. That is, the flow receiver becomes the flow processor.

Before you begin

Note the following points before configuring forwarding session rules in a cluster setup:

- You must configure linksets to be used for forwarding sessions.
- You must enable MAC Based Forwarding (MBF) on the cluster setup.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring Forwarding Session Rules in a Cluster Setup

Disabling steering for forwarding session rules in a cluster setup can be done at the following two levels:

- **Specific forwarding session rule level**. Enable the Process Local parameter while adding a new forwarding session rule or editing an existing forwarding session rule.
- **Global level**. Enable the Process Local parameter while adding a new cluster instance or editing an existing cluster instance. The global setting takes precedence over the forwarding session rule setting.

CLI procedures To disable steering for a forwarding session rule on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new forwarding session rule:
  - **add forwardingSession** <name> ((<network> [<netmask>]) | -**acl6name** <string> | -**aclname** <string>) -**processLocal ENABLED**
  - **show forwardingSession** <name>
- If reconfiguring an existing forwarding session rule:
  - **set forwardingSession** <name> -**processLocal ENABLED**
  - **show forwardingSession** <name>

To disable steering for all (global level) forwarding session rules on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new cluster instance:
  - **add cluster instance** <clid> -**processLocal Enabled**
  - **show cluster instance** <clid>
- If reconfiguring an existing cluster instance:
  - **set cluster instance** <clid> -**processLocal Enabled**
  - **show cluster instance** <clid>

Sample configuration:

Following are two examples of disabling steering at the forwarding session rule level, and an example of disabling steering at the global level.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
An IPv4 forwarding session rule:

> add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV4-1 10.102.105.51
   255.255.255.255 -processLocal Enabled
Done

An IPv6 forwarding session rule:

> add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV6-1  –acl6name ACL6-
   FWD-SESSN-1 -processLocal Enabled
Done

A cluster setup, with an instance ID 10, has steering disabled at
   global level:

> set cluster instance 10 -processLocal Enabled
Done
```

GUI procedures To disable steering for a forwarding session rule on a cluster setup by using the GUI:

Navigate to **System** > **Network** > **Forwarding Sessions**, select **Process Local** while adding a new forwarding session rule or editing an existing forwarding session rule.

To disable steering for all (global level) forwarding session rules on a cluster setup by using the GUI:

Navigate to **System** > **Cluster**, and select **Process Local** while adding a cluster configuration or modifying an existing cluster configuration.

Understanding VLANs

September 14, 2021

A Citrix ADC appliance supports Layer 2 port and IEEE 802.1q tagged VLANs. VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface as a part of multiple VLANs by using IEEE 802.1q tagging.

You can configure VLANs and bind them to IP subnets. The Citrix ADC then performs IP forwarding between these VLANs (if it is configured as the default router for the hosts on these subnets).

The Citrix ADC supports the following types of VLANs:

- **Port-Based VLANs.** The membership of a port-based VLAN is defined by a set of network interfaces that share a common, exclusive Layer 2 broadcast domain. You can configure multiple port-based VLANs. By default, all network interfaces on the Citrix ADC are members of VLAN 1.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If you apply 802.1q tagging to the port, the network interface belongs to a port-based VLAN. Layer 2 traffic is bridged within a port-based VLAN, and Layer 2 broadcasts are sent to all members of the VLAN if Layer 2 mode is enabled. When you add an untagged network interface as a member of a new VLAN, it is removed from its current VLAN.

- **Default VLAN.** By default, the network interfaces on the Citrix ADC are included in a single, port-based VLAN as untagged network interfaces. This VLAN is the default VLAN. It has a VLAN ID (VID) of 1. This VLAN exists permanently. It cannot be deleted, and its VID cannot be changed.

  When you add a network interface to a to a different VLAN as an untagged member, the network interface is automatically removed from the default VLAN. If you unbind a network interface from its current port-based VLAN, it is added to the default VLAN again.

- **Tagged VLANs.** 802.1q tagging (defined in the IEEE 802.1q standard) allows a networking device (such as the Citrix ADC) to add information to a frame at Layer 2 to identify the VLAN membership of the frame. Tagging allows network environments to have VLANs that span multiple devices. A device that receives the packet reads the tag and recognizes the VLAN to which the frame belongs. Some network devices do not support receiving both tagged and untagged packets on the same network interface—in particular, Force10 switches. In such cases, you need to contact customer support for assistance.

  The network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of one VLAN only (its native VLAN). This network interface transmits the frames for the native VLAN as untagged frames. A network interface can be a part of more than one VLAN if the other VLANs are tagged.

  When you configure tagging, be sure to match the configuration of the VLAN on both ends of the link. The port to which the Citrix ADC connects must be on the same VLAN as the Citrix ADC network interface.

  Note: This VLAN configuration is neither synchronized nor propagated, therefore you must perform the configuration on each unit in an HA pair independently.

Applying Rules to Classify Frames

VLANs have two types of rules for classifying frames:

- **Ingress rules.** Ingress rules classify each frame as belonging only to a single VLAN. When a frame is received on a network interface, the following rules are applied to classify the frame:
  - If the frame is untagged, or has a tag value equal to 0, the VID of the frame is set to the port VID (PVID) of the receiving interface, which is classified as belonging to the native VLAN. (PVIDs are defined in the IEEE 802.1q standard.)
  - If frame has a tag value equal to FFF, the frame is dropped.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

  - If the VID of the frame specifies a VLAN of which the receiving network interface is not a member, the frame is dropped. For example, if a packet is sent from a subnet associated with VLAN ID 12 to a subnet associated with VLAN ID 10, the packet is dropped. If an untagged packet with VID 9 is sent from the subnet associated with VLAN ID 10 to a network interface PVID 9, the packet is dropped.

- **Egress Rules.** The following egress rules are applied:

  - If the VID of the frame specifies a VLAN of which the transmission network interface is not a member, the frame is discarded.
  - During the learning process (defined by the IEEE 802.1q standard), the Src MAC and VID are used to update the bridge lookup table of the Citrix ADC.
  - A frame is discarded if its VID specifies a VLAN that does not have any members. (You define members by binding network interfaces to a VLAN.)

VLANs and Packet Forwarding on the Citrix ADC

The forwarding process on the Citrix ADC appliance is similar to that on any standard switch. However, the Citrix ADC performs forwarding only when Layer 2 mode is on. The key features of the forwarding process are:

- Topology restrictions are enforced. Enforcement involves selecting each network interface in the VLAN as a transmission port (depending on the state of the network interface), bridging restrictions (do not forward on the receiving network interface), and MTU restrictions.
- Frames are filtered on the basis of information in the bridge table lookup in the forwarding database (FDB) table of the Citrix ADC. The bridge table lookup is based on the destination MAC and the VID. Packets addressed to the MAC address of the Citrix ADC are processed at the upper layers.
- All broadcast and multicast frames are forwarded to each network interface that is a member of the VLAN, but forwarding occurs only if L2 mode is enabled. If L2 mode is disabled, the broadcast and multicast packets are dropped. This is also true for MAC addresses that are not currently in the bridging table.
- A VLAN entry has a list of member network interfaces that are part of its untagged member set. When forwarding frames to these network interfaces, a tag is not inserted in the frame.
- If the network interface is a tagged member of this VLAN, the tag is inserted in the frame when the frame is forwarded.

When a user sends any broadcast or multicast packets without the VLAN being identified, that is, during duplicate address detection (DAD) for NSIP or ND6 for the next hop of the route, the packet is sent out on all the network interfaces, with appropriate tagging based on either the Ingress and Egress rules. ND6 usually identifies a VLAN, and a data packet is sent on this VLAN only. Port-based VLANs are common to IPv4 and IPv6. For IPv6, the Citrix ADC supports prefix-based VLANs.

Configuring a VLAN

September 14, 2021

You can implement VLANs in the following environments:

- Single subnet
- Multiple subnets
- Single LAN
- VLANs (no tagging)
- VLANs (802.1q tagging)

If you configure VLANs that have only untagged network interfaces as their members, the total number of possible VLANs is limited to the number of network interfaces available in the Citrix ADC. If more IP subnets are required with a VLAN configuration, 802.1q tagging must be used.

When you bind a network interface to a VLAN, the network interface is removed from the default VLAN. If the network interfaces need to be a part of more than one VLAN, you can bind the network interfaces to the VLANs as tagged members.

You can configure the Citrix ADC to forward traffic between VLANs at Layer 3. In this case, a VLAN is associated with a single IP subnet. The hosts in a VLAN that belong to a single subnet use the same subnet mask and one or more default gateways connected to that subnet. Configuring Layer 3 for a VLAN is optional. Layer 3 is used for IP forwarding (inter-VLAN routing). Each VLAN has a unique IP address and subnet mask that define an IP subnet for the VLAN. In an HA configuration, this IP address is shared with the other Citrix ADC appliances. The Citrix ADC forwards packets between configured IP subnets (VLANs).

When you configure the Citrix ADC, you must not create overlapping IP subnets. Doing so impedes Layer 3 functionality.

Each VLAN is a unique Layer 2 broadcast domain. Two VLANs, each bound to separate IP subnets, cannot be combined into a single broadcast domain. Forwarding traffic between two VLANs requires a Layer 3 forwarding (routing) device, such as the Citrix ADC appliance.

Configuring VLANs in an HA Setup

VLAN configuration for a high-availability setup requires that the Citrix ADC appliances have the same hardware configuration, and the VLANs configured on them must be mirror images.

The correct VLAN configuration is implemented automatically when the configuration is synchronized between the Citrix ADC appliances. The result is identical actions on all the appliances. For example,

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

adding network interface 0/1 to VLAN2 adds this network interface to VLAN 2 on all the appliances participating in the high-availability setup.

Note: If you use network-interface-specific commands in an HA setup, the configurations you create are not propagated to the other Citrix ADC appliance. You must perform these commands on each appliance in an HA pair to ensure that the configuration of the two appliances in the HA pair remains synchronized.

Creating or Modifying a VLAN

To configure a VLAN, you create a VLAN entity, and then bind network interfaces and IP addresses to the VLAN. If you remove a VLAN, its member interfaces are added to the default VLAN.

CLI procedures

To create a VLAN by using the CLI:

At the command prompt, type:

- `add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED|DISABLED)]`
- `sh vlan <id>`

Example:

```
1    > add vlan 2  – aliasName "Network A"   Done
```

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -ifnum <slot/port>`
- `sh vlan <id>`

Example:

```
1    > bind vlan 2 -ifnum 1/8   Done
```

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -IPAddress <IPAddress> <netMask>`
- `sh vlan <id>`

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
1    > bind vlan 2 -IPAddress 10.102.29.54 255.255.255.0   Done
```

To remove a VLAN by using the CLI:

At the command prompt, type:

- `rm vlan <id>`

GUI procedures

To configure a VLAN by using the GUI:

1. Navigate to System > Network > VLANs, add a new VLAN, or edit an existing VLAN.
2. To bind an IP address to a VLAN, under IP Bindings, select the Active option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The Type column displays the IP address type (such as mapped IP, virtual IP, or subnet IP) for each IP address in the IP Address column.
3. To bind a network interface to a VLAN, under Interface Bindings, select the Active option corresponding to the interface that you want to bind to the VLAN.

Monitoring VLANs

You can display VLAN statistics such as packets received, bytes received, packets sent, and bytes sent, and use the information to identify anomalies and or debug a VLAN.

To view the statistics of a VLAN by using the CLI:

At the command prompt, type:

- `stat vlan <vlanID>`

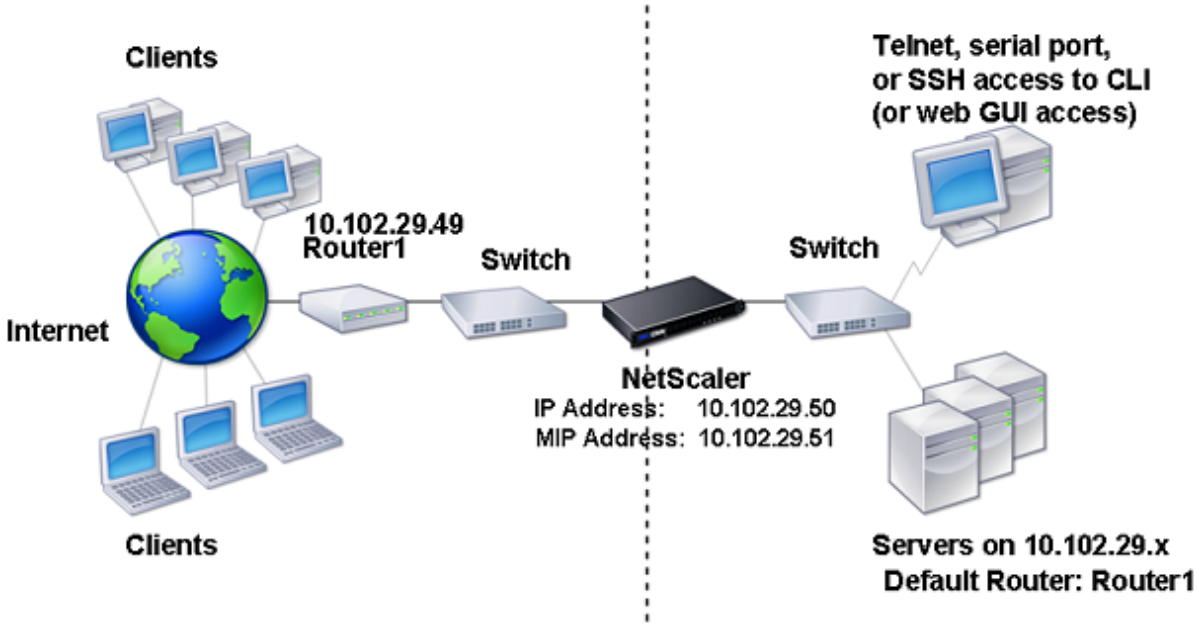
Example:

```
1    stat vlan 2
```

To view the statistics of a VLAN by using the GUI:

1. Navigate to System > Network > VLANs.
2. Select the VLAN, and click Statistics.

Configuring VLANs on a Single Subnet



September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Before configuring a VLAN on a single subnet, make sure that Layer 2 Mode is enabled.

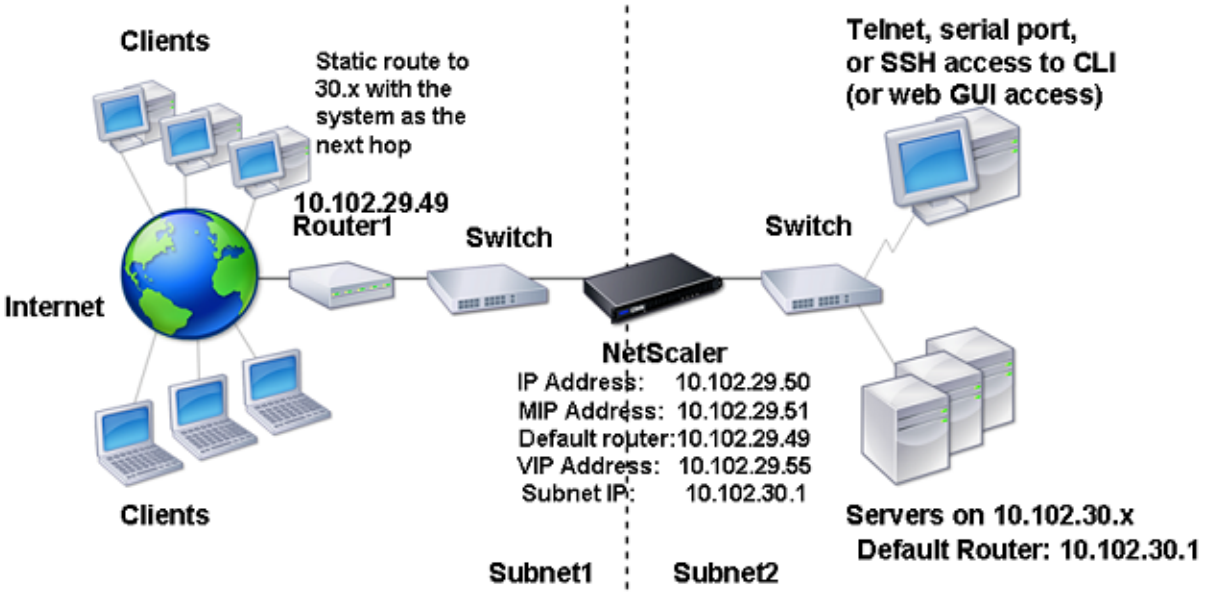
The following figure shows a single subnet environment

Figure 1. VLAN on a Single Subnet

In the above figure:

1. The default router for the Citrix ADC and the servers is Router 1.
2. Layer 2 mode must be enabled on the Citrix ADC for the Citrix ADC to have direct access to the servers.
3. For this subnet, a virtual server can be configured for load balancing on the Citrix ADC appliance.

To configure a VLAN on a single subnet, follow the procedures described in Configuring a VLAN.



Configuring VLANs on Multiple Subnets

September 14, 2021

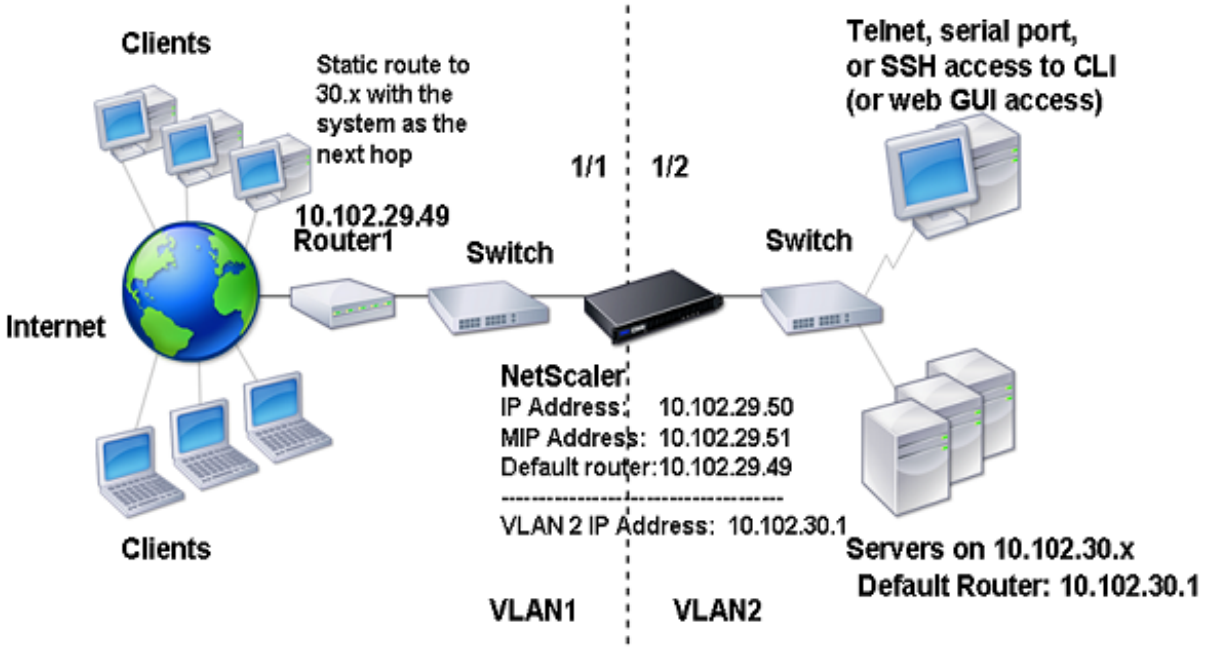
To configure a single VLAN across multiple subnets, you must add a VIP for the VLAN and configure the routing appropriately. The following figure shows a single VLAN configured across multiple subnets.

Figure 1. Multiple Subnets in a Single VLAN

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure a single VLAN across multiple subnets, perform the following tasks:

1. Disable Layer 2 mode. For the procedure to disable Layer 2 mode, see Packet forwarding modes.
2. Add a VIP address. For the procedure to add a VIP address, see Configuring and Managing Virtual IP Addresses (VIPs).
3. Configure RNAT rule. For the procedure to configure the RNAT ID, see Configuring RNAT.



Configuring Multiple Untagged VLANs across Multiple Subnets

September 14, 2021

In environments with multiple untagged VLANs across multiple subnets, a VLAN is configured for each IP subnet. A network interface is bound to one VLAN only. The following figure shows this configuration.

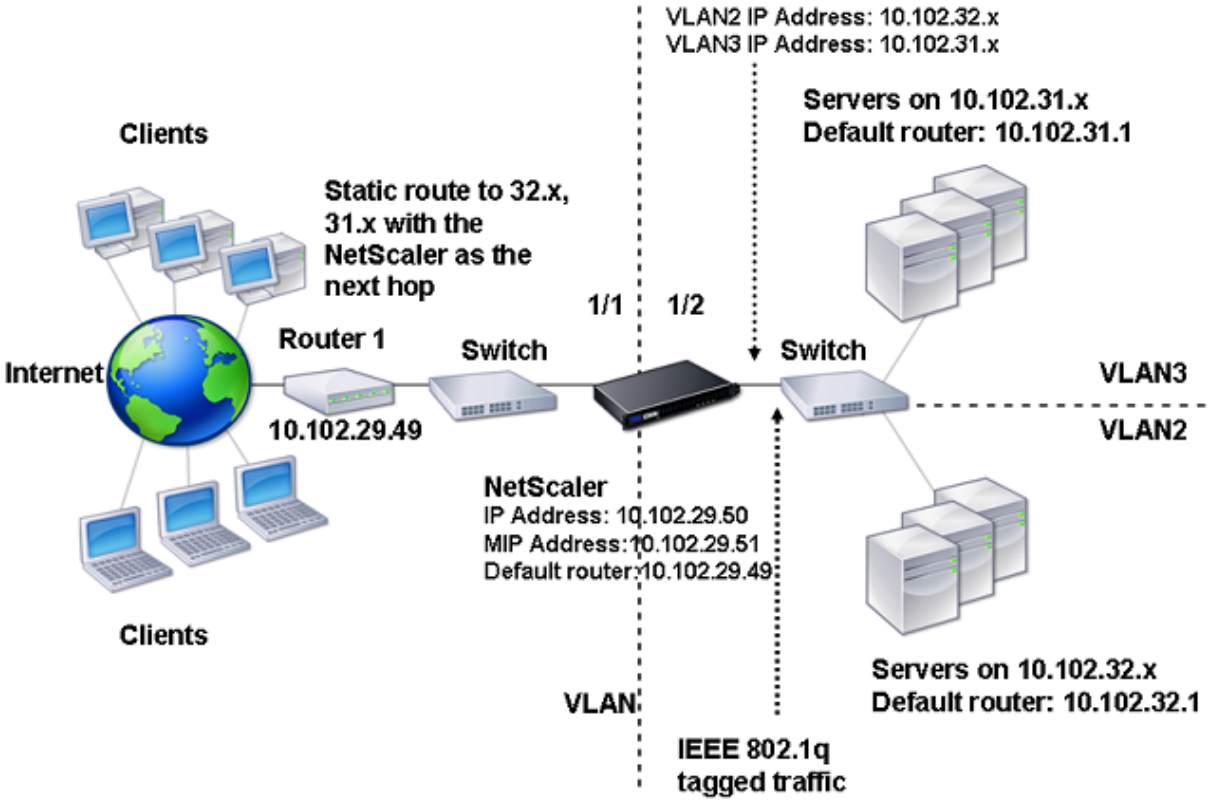
Figure 1. Multiple Subnets with VLANs - No Tagging

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the Citrix ADC to VLAN 2 as an untagged network interface.
3. Bind the IP address and subnet mask to VLAN 2.

For procedures on these tasks, see Configuring a VLAN.



Configuring Multiple VLANs with 802.1q Tagging

September 14, 2021

For multiple VLANs with 802.1q tagging, each VLAN is configured with a different IP subnet. Each network interface is in one VLAN. One of the VLANs is set up as tagged. The following figure shows this configuration.

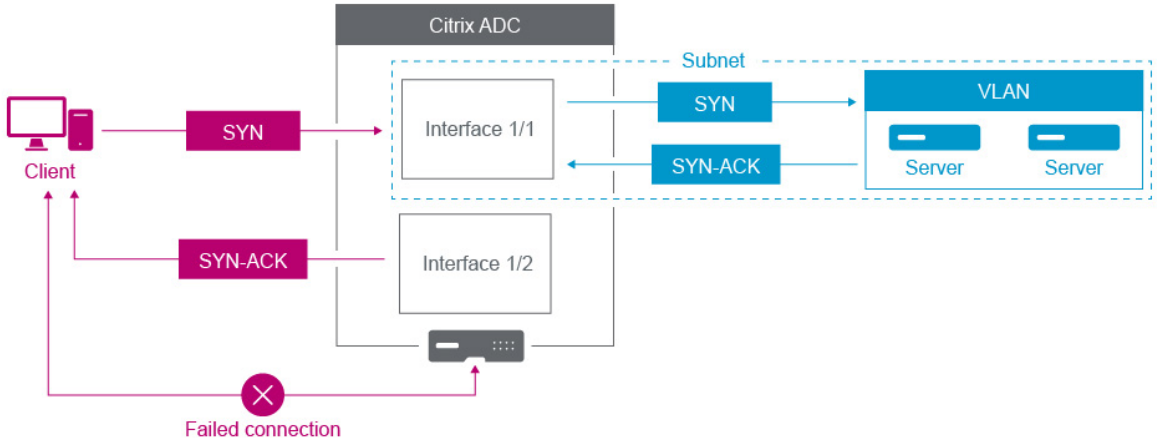
Figure 1. Multiple VLANs with IEEE 802.1q Tagging

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the Citrix ADC to VLAN 2 as an untagged network interface.
3. Bind the IP address and netmask to VLAN 2.
4. Add VLAN 3.
5. Bind the 1/2 network interface of the Citrix ADC to VLAN 3 as a tagged network interface.
6. Bind the IP address and netmask to VLAN 3.

For procedures on these tasks, see Configuring a VLAN.



Associate an IP Subnet with a Citrix ADC Interface by Using VLANs

September 14, 2021

BY default, a Citrix ADC appliance does not provide any differentiation between network interfaces. The appliance functions more like a network hub than a switch. This can lead to Layer 3 network loops where duplicated traffic is transmitted on multiple interfaces.

In such scenarios, depending on network design, it is possible that a request could be transmitted on one interface and the corresponding response is received on a different interface.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For example, a SYN packet sent on one interface and the SYN-ACK response received on a different interface can result in a failed connection, as the appliance expects to receive the SYN-ACK on the same interface that sent the original SYN packet.

To resolve such issues, the appliance can use internal or external VLANs, to associate specific subnets with interfaces.

Before you begin

Before you begin associating an IP Subnet with a Citrix ADC interface by using VLANs, note the following points:

- The network connectivity might be accidentally lost when associating a VLAN to the subnet or interface that is currently being used to access the Citrix ADC GUI or command line interface. Therefore, in such scenarios, it is highly recommended that the change is made by accessing the command line interface through the serial console of a physical Citrix ADC appliance or through the virtual serial console of a Citrix ADC VPX.
- Citrix ADC management interfaces lack certain hardware optimization features which makes them less desirable for use with production data traffic. As such, it is recommended that the Citrix ADC be configured to only use the management interfaces for management (NSIP) traffic. In the default configuration, there is no logical differentiation between the management interfaces and data interfaces on a hardware NetScaler. In order to accomplish this goal, it is recommended that the NSIP be on a separate VLAN from data traffic, which allows management traffic to be on a separate interface.

  Although the concept is the same, to change the VLAN associations of the subnet that contains the NSIP address, you must configure NSVLAN instead of the below instructions. Such changes will also require a reboot of the Citrix ADC in order to take effect. For more information, see Configuring NSVLAN.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- On Citrix ADC SDX, it is highly recommended that the NSIP of each instance be on the same subnet and VLAN as the SDX's SVM (Management Service GUI) and XenServer. The SVM communicates with instances via the network. If the SVM, XenServer, and instances are not on the same VLAN and subnet, management traffic must flow outside of the SDX. In this situation, network issues can cause Instance state to show up as yellow or red and can prevent the management and configuration changes of the Citrix ADC instances.

Configuration Steps

Associate an IP subnet with a Citrix ADC Interface consists of the following tasks:

Add a VLAN. While adding a VLAN, if you are tagging the VLAN, then you must select a VLAN number that is defined in the network switch for the associated switch port. If the VLAN is untagged and is internal to the appliance, then it is recommended that you select the VLAN number that is available in the switch configuration for easy reference.

Bind an interface to the VLAN. While binding, if you are using Link Aggregation, associate the VLAN with the LA channel (for example, LA/1) instead of the physical interface. The VLAN must be associated with only one network interface.

If you want to tag the traffic on the interface, use the tagged (Tag) option. Else, the traffic leaves the appliance untagged and is associated with the native VLAN of the switch port.

Bind an IP address to the VLAN. While binding, if you bind more than one IP address from the same subnet, an error occurs. When an IP address is associated with a VLAN, all IP addresses in that subnet are automatically associated with the VLAN.

> **Note:**
>
> In a high availability (HA) setup, these VLAN configurations are added automatically from the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> primary node to the secondary node during HA synchronization. For more information about high availability setups, see High Availability.

CLI procedures

To add a VLAN by using the CLI:

At the command prompt, type:

- **add vlan** <id>
- **sh vlan** <id>

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- **bind vlan** <id> -**ifnum** <slot/port>
- **sh vlan** <id>

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- **bind vlan** <id> -**IPAddress** <IPAddress> <netMask>
- **sh vlan** <id>

Example:

```
> add vlan 100

> bind vlan 100 -ifnum 1/1

> bind vlan 100 -ipAddress 10.0.1.0 255.255.255.0
```

GUI procedures

To configure a VLAN by using the GUI:

1. Navigate to **System** > **Network** > **VLANs**, add a new VLAN.
2. To bind a network interface to a VLAN, under **Interface Bindings**, select the **Active** option corresponding to the interface that you want to bind to the VLAN.
3. To bind an IP address to a VLAN, under **IP Bindings**, select the **Active** option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The **Type** column displays the IP address type for each IP address in the **IP Address** column.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Citrix ADC appliance networking and VLAN best practices

September 14, 2021

A Citrix ADC appliance uses VLANs to determine which interface must be used for which traffic. In addition, Citrix ADC appliance does not participate in Spanning Tree. Without the proper VLAN configuration, the Citrix ADC appliance is unable to determine which interface to use, and it can function more like a HUB than a switch or a router. In other words, the Citrix ADC appliance can use all interfaces for each conversation.

Symptoms of VLAN misconfiguration

VLAN misconfiguration issue can manifest itself in many forms, including performance issues, inability to establish connections, randomly disconnected sessions, and in severe situations, network disruptions seemingly unrelated to the Citrix ADC appliance itself. The Citrix ADC appliance may also report MAC moves, muted interfaces, and/or management interface transmit or receive buffer overflows, depending on the exact nature of the interaction with your network.

MAC Moves (counter nic_tot_bdg_mac_moved): This issue indicates that the Citrix ADC appliance is using more than one interface to communicate with the same device (MAC address), because it could not properly determine which interface to use.

Muted interfaces (counter nic_err_bdg_muted): This issue indicates that the Citrix ADC appliance has detected that it is creating a routing loop due to VLAN configuration issues, and as such, it has shut down one or more of the offending interfaces in order to prevent a network outage.

Interface buffer overflows, typically referring to management interfaces (counter nic_err_tx_overflow):This issue can be caused if too much traffic is being transmitted over a management interface. Management interfaces on the Citrix ADC appliance is not designed to handle large volumes of traffic, which may result from network and VLAN misconfigurations triggering the Citrix ADC appliance to use a management interface for production data traffic. This often occurs because the Citrix ADC appliance has no way to differentiate traffic on the VLAN / subnet of the NSIP (NSVLAN) from regular production traffic. It is highly recommended that the NSIP be on a separate VLAN and subnet from any production devices such as workstations and servers.

Orphan ACKs (counter tcp_err_orphan_ack): This issue indicates that the Citrix ADC appliance received an ACK packet that it was not expecting, typically on a different interface than the ACK'd traffic originated from. This situation can be caused by VLAN misconfigurations where the Citrix ADC appliance transmits on a different interface than the target device would typically use to communicate with the Citrix ADC appliance (often seen in conjunction with MAC moves)

High rates of retransmissions or retransmit give ups (counters: tcp_err_retransmit_giveups,

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

tcp_err_7th_retransmit, various other retransmit counters): The Citrix ADC appliance attempts to retransmit a TCP packet a total of 7 times before it gives up and terminates the connection. While this situation can be caused by network conditions, it often occurs as a result of VLAN and interface misconfiguration.

High Availability Split Brain: Split Brain is a condition where both high availability nodes believe they are Primary, leading to duplicate IP addresses and loss of Citrix ADC appliance functionality. This is caused when the two high availability nodes cannot communicate with each-other using high availability Heartbeats on UDP Port 3003 using the NSIP, across any interface. This is typically caused by VLAN misconfigurations where the native VLAN on the Citrix ADC appliance interfaces does not have connectivity between Citrix ADC appliances.

Best practices for VLAN and network configurations

1. Each subnet must be associated with a VLAN.
2. More than one subnet can be associated with the same VLAN (depending on your network design).
3. Each VLAN should be associated to only one interface (for purposes of this discussion, a LA channel counts as a single interface).
4. If you require more than one subnet to be associated with an interface, the subnets must be tagged.
5. Contrary to popular belief, the Mac-Based-Forwarding (MBF) feature on the Citrix ADC appliance is not designed to mitigate this type of issue. MBF is designed primarily for the DSR (Direct Server Return) mode of the Citrix ADC appliance, which is rarely used in most environments (it is designed to allow traffic to purposely bypass the Citrix ADC appliance on the return path from the back-end servers). MBF may hide VLAN issues in some instances, but it should not be relied-upon to resolve this type of problem.
6. Every interface on Citrix ADC appliance requires a native VLAN (unlike Cisco, where native VLANs are optional), although the TagAll setting on an interface can be used so that no untagged traffic leaves the interface in question.
7. The native VLAN can be tagged if necessary for your network design (this is the TagAll option for the interface).
8. The VLAN for the subnet of your Citrix ADC appliance's NSIP is a special case. This is called the NSVLAN. The concepts are the same but the commands to configure it are different and changes to the NSVLAN require a reboot of the Citrix ADC appliance to take effect. If you attempt to bind a VLAN to a SNIP that shares he same subnet as the NSIP, you get "Operation not permitted."This is because you have to use the NSVLAN commands instead. Also, on some firmware versions, you

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

cannot set an NSVLAN if that VLAN number exists using `add VLAN` command. Simply remove the VLAN and then set the NSVLAN again.

9. High availability Heartbeats always use the Native VLAN of the respective interface (optionally tagged if the TagAll option is set on the interface).

10. There must be communication between at least one set of Native VLAN(s) on the two nodes of an high availability pair (this can be direct or via a router). The native VLANs are used for high availability heartbeats. If the Citrix ADC appliances cannot communicate between native VLANs on any interface, this will lead to high availability failovers and possibly a split-brain situation where both Citrix ADC appliances think they are primary (leading to duplicate IP addresses, amongst other things).

11. The Citrix ADC appliance does not participate in spanning tree. As such, it is not possible to use spanning tree to provide for interface redundancy when using a Citrix ADC appliance. Instead, use a form of Link Aggregation (LACP or manual LAG) for this purpose.

    Note: If you want to have link aggregation between multiple physical switches, you must have the switches configured as a virtual switch, using a feature such as Cisco's Switch Stack.

12. The high availability synchronization and command Propagation, by default, use the NSIP/NSVLAN. To separate these out to a different VLAN, you can use the SyncVLAN option of the `set HA node` command.

13. There is nothing built-in to the Citrix ADC appliance default configuration that denotes that a management interface (0/1 or 0/2) is restricted to management traffic only. This restriction must be enforced by the end user through VLAN configuration. The management interfaces are not designed to handle data traffic, so your network design must take this point into account. Management interfaces, contained on the Citrix ADC appliance motherboard, lack various offloading features such as CRC offload, larger packet buffers, and other optimizations, making them much less efficient in handling large amounts of traffic. To separate production data and management traffic, the NSIP must not be on the same subnet/VLAN as your data traffic.

14. If it is desired to use a management interface to carry management traffic, it is best practice that the Default Route be on a subnet other than the subnet of the NSIP (NSVLAN).

    In many configurations, the default route is relied-upon for workstation commmunication (in an internet scenario). If the default route is on the same subnet as the NSIP, then the ADC appliance can use the management interface to send and receive data traffic. This use of data traffic can overload the management interface.

15. Also, an SDX-the SVM, XenServer, and all Citrix ADC instance NSIPs must be on the same VLAN and subnet. There is no **backplane** in the SDX appliance that allows for communication between SVM/Xen/Instances. If they are not on the same VLAN/subnet/interface, traffic between them must leave the physical hardware, be routed on your network, and return.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

This configuration can lead to obvious connectivity issues between the instances and SVM and as such, is not recommended. A common symptom of this is a Yellow Instance State indicator in the SVM for the VPX instance in question, and the inability to use the SVM to reconfigure a VPX instance.

16. If some VLANs are bound to subnets and some are not, during a high availability failover, GARP packets are not be sent for any IP addresses on any of the subnets that are not bound to a VLAN. This configuration can cause dropped connections and connectivity issues during high availability failovers. This issue is caused because the Citrix ADC appliance cannot notify the network MAC ownership IP addresses change on non-VMAC-configured Citrix ADC appliances.

    Symptoms of this are that during/after a high availability failover, the ip_tot_floating_ip_err counter increments on the former primary Citrix ADC appliance for more than a few seconds, indicating that the network did not receive or process GARP packets and the network is continuing to transmit data to the new secondary Citrix ADC appliance.

Configuring NSVLAN

August 10, 2022

NSVLAN is a VLAN to which the Citrix ADC management IP (NSIP) address's subnet is bound. The NSIP subnet is available only on interfaces that are associated with NSVLAN. By default, NSVLAN is VLAN 1, but you can designate a different VLAN as NSVLAN. If you do so, you must reboot the Citrix ADC appliance for the change to take effect. After the reboot, NSIP subnet traffic is restricted to the new NSVLAN.

The traffic from the Citrix ADC IP subnet can be tagged (802.1q) with the VLAN ID specified for NSVLAN. You must configure the attached switch interface to tag and allow this same VLAN ID on the connected interface. If you remove your NSVLAN configuration, the NSIP subnet is automatically bound to VLAN 1, restoring the default NSVLAN.

To configure NSVLAN by using the CLI:

At the command prompt, type:

```
set ns config -nsvlan -ifnum …[-tagged (YES NO)]
```

-
- show ns config

  Note: The configuration takes effect after the Citrix ADC appliance is rebooted.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
> set ns config -nsvlan 300 -ifnum 1/1 1/2 1/3 -tagged YES
 Done

> save config
 Done
```

To restore the default NSVLAN configuration by using the CLI:

At the command prompt, type:

- unset ns config -nsvlan
- show ns config

Example:

```
> unset ns config -nsvlan
 Done
```

To configure NSVLAN by using the GUI:

Navigate to System > Settings, in the Settings group, click Change NSVLAN Settings.

Setting the MTU on the NSVLAN

By default, the MTU of the NSVLAN is set to 1500 bytes. You can modify this setting to optimize throuhput and network performance. For example, you can configure the NSVLAN to process jumbo frames.

To set the MTU of the NSVLAN by using the CLI:

At the command prompt, type:

- **set vlan** <id> **-mtu** <positive_integer>
- **show vlan** <id>

To set the MTU of the NSVLAN by using the GUI:

Navigate to **System** > **Network** > **VLANs**, open the NSVLAN, and set the **Maximum Transmission Unit** parameter.

Sample configuration:

In the following sample configuration, VLAN 100 is the NSVLAN.

```
> set ns config -nsvlan 100 -ifnum 1/1 -tagged no

  Warning: The configuration must be saved and the system rebooted for
     these settings to take effect

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> set vlan 100 -mtu 1600

  Done

> sh vlan

  1)  VLAN ID: 1

      Link-local IPv6 addr:
    fe80::947b:52ff:fead:12d5/64

      Interfaces : 1/2 LO/1

  2)  VLAN ID: 100    VLAN Alias Name:

      MTU: 1600

      Interfaces : 1/1

      IPs :

          10.102.53.114     Mask: 255.255.255.0

  Done

> save config

  Done
```

Configuring Allowed VLAN List

September 14, 2021

Citrix ADC accepts and sends tagged packets of a VLAN on an interface if the VLAN is explicitly configured on the Citrix ADC appliance and the interface is bound to the VLAN. Some deployments (for example, Bump in the wire) require the Citrix ADC appliance to function as a transparent device to accept and forward tagged packets related to a large number of VLANs. For this requirement, configuring and managing a large number of VLANs is not a feasible solution.

Allowed VLAN list on an interface specifies a list of VLANs. The interface transparently accepts and sends tagged packets related to the specified VLANs without the need for explicitly configuring these VLANs on the appliance.

Points to Consider before Configuring Allowed VLAN List

Consider the following points before configuring allowed VLAN list

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- In a high availability setup, allowed VLAN list is not propagated or synchronized. Therefore, you have to configure allowed VLAN list on both the nodes.
- The traffic of a native VLAN might leak to the non-member interfaces that specifies the native VLAN in its allowed VLAN list.
- A Maximum of 60 VLAN ranges can be specified as part of allowed VLAN list for an interface.
- The Citrix ADC appliance does not support allowed VLAN list on interfaces that are part of link aggregation channels or redundant interface sets. For more information on redundant interface set, see Redundant Interface Set.
- Allowed VLAN list is not supported on a Citrix ADC cluster configuration.
- The Citrix ADC appliance does not support allowed VLAN list for Bridge groups.
- The Citrix ADC appliance does not support allowed VLAN list for VXLANs.

Configuring Allowed VLAN List

To configure allowed VLAN list by using the CLI:

At the command prompt, type:

- **set interface** <id> **-trunkmode** (ON|OFF) **-trunkAllowedVlan** <int[-int]> …
- **show interface** <id>

To configure allowed VLAN list by using the GUI:

Navigate to **System** > **Network** > **Interfaces**, select a network interface, click **Edit**, and then set the following parameters:

- Trunk Mode
- Trunk Allowed VLAN

Sample Configuration:

In the following sample configuration, VLANS in the ranges 100-120, 190-200, and 300-330 are specified as part of allowed VLAN list for interface 1/2.

```
> set int 1/2 -trunkmode on -trunkallowedVlan 100-120 190-200 300-330

Done

> sh int 1/2

1)      Interface 1/2 (Gig Ethernet 10/100/1000 MBits) #6
        flags=0xc020

        <ENABLED, UP, UP, AUTONEG OFF, HEARTBEAT, 802.1q, trunkmode>

        Trunk Allowed Vlans:  100-120 190-200 300-330

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
14 Done
```

Configuring Bridge Groups

September 14, 2021

Typically, when you want to merge two or more VLANs into a single domain, you change the VLAN configuration on all the devices in the separate domains. This can be a tedious task. To more easily merge multiple VLANs into a single broadcast domain, you can use bridge groups.

The bridge groups feature works the same way as a VLAN. Multiple VLANS can be bound to a single bridge group, and all VLANs bound to same bridge group form a single broadcast domain. You can bind only Layer 2 VLANs to a bridge group. For Layer 3 functionality, you must assign an IP address to a bridge group.

In Layer 2 mode, a broadcast packet received on an interface belonging to a particular VLAN is bridged to other VLANs that belong to the same bridge group. In the case of a unicast packet, the Citrix ADC appliance searches its bridge table for the learned MAC addresses of all the VLANs belonging to same bridge group.

In Layer 3 forwarding mode, an IP subnet is bound to a bridge group. The Citrix ADC accepts incoming packets belonging to the bound subnet and forwards the packets only on VLANs that are bound to the bridge group.

IPv6 routing can be enabled on a configured bridge group.

> **Note**
>
> Bridge Group feature and Bridge BPDU mode cannot work together.

Configuration steps

Perform the following steps to configure a bridge group:

- Enable Layer 2 mode
- Add a bridgegroup and bind VLANs to the bridgegroup

CLI procedures

To enable Layer 2 mode by using the CLI:
At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **enable ns mode l2**
- **show ns mode**

To add a bridge group and bind VLANs by using the CLI:

At the command prompt, type:

- **add bridgegroup** <id> [-**ipv6DynamicRouting** (**ENABLED** | **DISABLED**)]
- **bind bridgegroup** <id> -**vlan** <positive_integer>
- **show bridgegroup** <id>

Example:

```
> add bridgegroup 12
 Done
```

To remove a bridge group by using the CLI:

At the command prompt, type:

- **rm bridgegroup** <id>

Example:

```
 rm bridgegroup 12
```

GUI Procedures

To configure a bridge group by using the GUI:

Navigate to **System** > **Network** > **Bridge Groups**, add a new bridge group and bind VLANs to the bridgegroup, or edit an existing bridge group.

Configuring virtual MACs

September 14, 2021

The primary and secondary nodes in a high availability (HA) setup share the virtual MAC address floating entity. The primary node owns the floating IP addresses (such as MIP, SNIP, and VIP) and responds to ARP requests for these IP addresses with its own MAC address. Therefore, the ARP table of an external device, such as an upstream router, is updated with the floating IP address and the MAC address of the primary node.

When a failover occurs, the secondary node takes over as the new primary node. The former secondary node uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it had learned

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

from the old primary node. The MAC address that the new primary node advertises is the MAC address of its own network interface. Some devices (a few routers) do not accept these GARP messages. Therefore, these external devices retain the IP address-to-MAC address mapping that the old primary node had advertised. This can result in a GSLB site going down.

Therefore, you must configure a virtual MAC on both nodes of an HA pair. This means that both nodes have identical MAC addresses. When a failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

For the procedures to configure a virtual MAC, see Configuring Virtual MAC Addresses.

Configuring Link Aggregation

September 14, 2021

Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the Citrix ADC appliance and other connected devices. An aggregated link is also referred to as a "channel."You can configure the channels manually, or you can use Link Aggregation Control Protocol (LACP). You cannot apply LACP to a manually configured channel, nor can you manually configure a channel created by LACP.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. (That is, the network interface parameters are ignored.) A network interface can be bound only to one channel.

When a network interface is bound to a channel, it drops its VLAN configuration. When network interfaces are bound to a channel, either manually or by LACP, they are removed from the VLANs that they originally belonged to and added to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you bind the network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then bind them to a channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them back to VLAN 2.

Configuring Link Aggregation Manually

When you create a link aggregation channel, its state is DOWN until you bind an active interface to it. You can modify a channel at any time. You can remove channels, or you can enable/disable them.

CLI procedures

To create a link aggregation channel by using the CLI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

At the command prompt, type:

- add channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)][-tagall (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
- show channel

Example:

```
> add channel LA/1 -ifnum 1/8
Done
```

To bind an interface to or unbind an interface from an existing link aggregation channel by using the CLI:

At the command prompt, type one of the following commands:

- bind channel <id> <interfaceName>
- unbind channel <id> <interfaceName>

Example:

```
bind channel LA/1 1/8
```

To modify a link aggregation channel by using the CLI:

At the command prompt, type the
set channel command, the channel ID, and the parameters to be changed, with their new values.

To remove a link aggregation channel by using the CLI:

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

At the command prompt, type:

- rm channel <id>

Example:

```
> rm channel LA/1
 Done
```

GUI procedures

To configure a link aggregation channel by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Navigate to System > Network > Channels, add a new channel, or edit an existing channel.

To remove a link aggregation channel by using the GUI:

> **Important:**
>
> When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

Navigate to System > Network > Channels, select the channel that you want to remove and click Delete.

Configuring Link Aggregation by Using the Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) enables network devices to exchange link aggregation information by exchanging LACP Data Units (LACPDUs). Therefore, you cannot enable LACP on network interfaces that are members of a channel that you created manually.

When using LACP to configure link aggregation, you use different commands and parameters for modifying link aggregation channels than you do for creating link aggregation channels. To remove a channel, you must disable LACP on all interfaces that are part of the channel.

Note: In an High Availability configuration, LACP configurations are neither propagated nor synchronized.

Configuring the LACP System Priority

The LACP system priority determines which peer device of an LACP LA channel can have control over the LA channel. This number is globally applied to all LACP channels on the appliance. The lower the value, the higher the priority.

To configure the LACP system priority by using the CLI:

At the command prompt, type the following commands to set the priority for a standalone appliance and verify the configuration:

- set lacp -sysPriority <positive_integer>
- show lacp

Example:

```
1 set lacp -sysPriority 50
```

To set the priority for a specific cluster node, log on to the cluster IP address and at the command prompt, type the following commands:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- set lacp -sysPriority <positive_integer> -ownerNode <positive_integer>
- show lacp

Example:

```
set lacp -sysPriority 50 -ownerNode 2
```

To configure the LACP system priority by using the GUI:

1. Navigate to System > Network > Interfaces and, in the Action list, select Set LACP.
2. Specify the system priority and the owner node (applicable only for a cluster setup).

Creating Link Aggregation Channels

For creating a link aggregation channel by using LACP, you need to enable LACP and specify the same LACP key on each interface that you want to be the part of the channel. For example, if you enable LACP and set the LACP Key to 3 on interfaces 1/1 and 1/2, a link aggregation channel LA/3 is created and interfaces 1/1 and 1/2 are automatically bound to it.

Note:

- When enabling LACP on a network interface, you must specify the LACP Key.
- By default, LACP is disabled on all network interfaces.

To create an LACP channel by using the CLI:

At the command prompt, type:

- set interface <id> [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)]
- show interface [<id>]

To create an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and set the parameters.

Modifying Link aggregation Channels

After you have created an LACP channel by specifying interfaces, you can modify properties of the channel.

To modify an LACP channel by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- set channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-tagall (ON | OFF)] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
- show channel

Example:

```
> set channel LA/3 -state ENABLED -speed 10000
 Done
```

To modify an LACP channel by using the GUI:

Navigate to System > Network > Channels, and modify an existing LACP channel.

Removing a Link Aggregation Channel

To remove a link aggregation channel that was created by using LACP, you need to disable LACP on all the interfaces that are part of the channel.

To remove an LACP channel by using the CLI:

At the command prompt, type:

- set interface <id> -lacpMode Disable
- show interface [<id>]

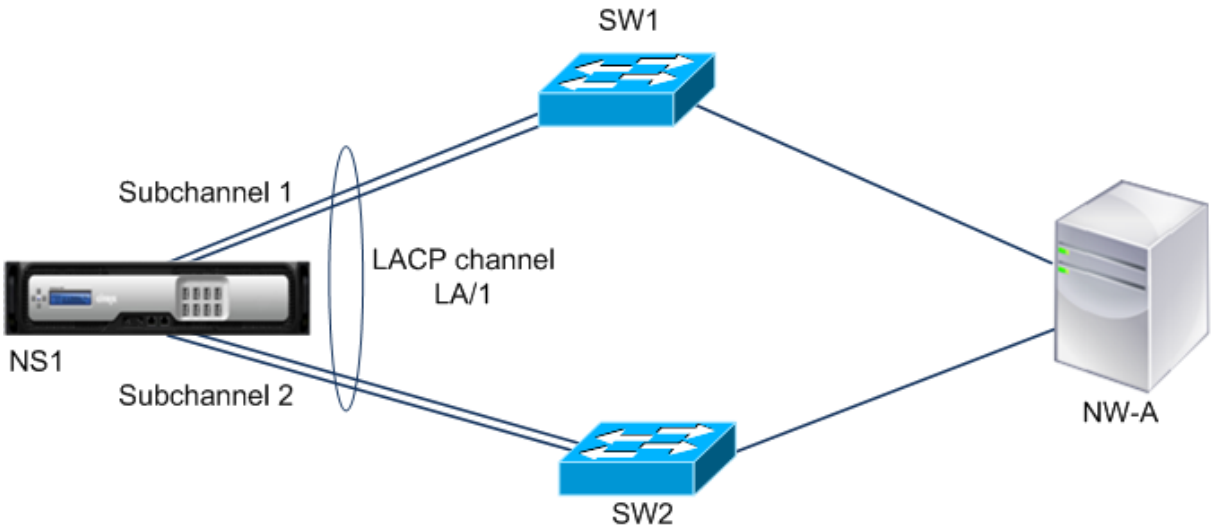
To remove an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and clear the Enable LACP option.

Link Redundancy using LACP channels

Link Redundancy using LACP channels enables the Citrix ADC to divide an LACP channel into logical subchannels, with one subchannel active and the others in standby mode. If the active subchannel fails to meet a minimum threshold of throughput, one of the standby subchannels becomes active and takes over.

A subchannel is created from links that are part of the LACP channel and are connected to a particular device. For example, for an LACP channel with four interfaces on a Citrix ADC, with two of the interfaces connected to device A and the other two connected to device B, the ADC creates two logical subchannels, one subchannel with two links to device A, and another subchannel with two links to device B.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure link redundancy for an LACP channel, set the lrMinThroughput parameter, which specifies the minimum throughput threshold (in Mbps) to be met by the active subchannel. Setting this parameter automatically creates the subchannels. When the maximum supported throughput of the active channel falls below the lrMinThroughput value, link failover occurs and a standby subchannel becomes active.

If you unset the lrMinThroughput parameter of an LACP channel, or set the value to zero, link redundancy for that channel is disabled, which is the default setting.

Example

Consider an example of link redundancy configured between Citrix ADC NS1 and switches SW1 and SW2.

NS1 is connected to network device NW-A through SW1 and SW2.
On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000Mbps.
When the lrMinThroughput parameter is set to some value (say 2000), NS1 creates two logical subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2).

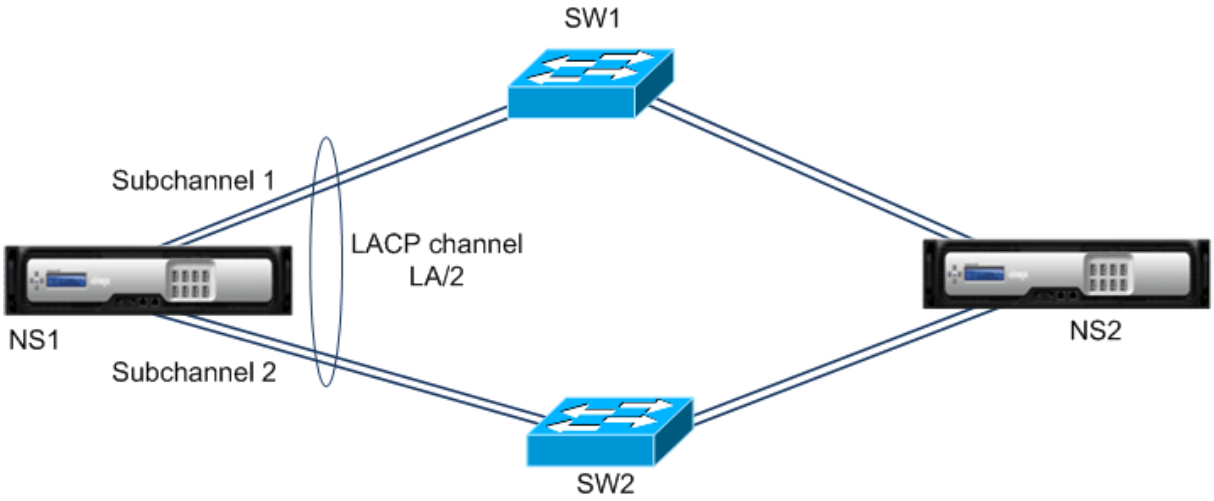
NS1 applies an algorithm to make one subchannel (say subchannel 1) active and put the other on standby. NS1 and network device NW-A are accessible to each other through only the active subchannel.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Link Redundancy using LACP channels in a High Availability setup

In a high availability (HA) configuration, if you want to configure throughput (throughput parameter) based HA failover and link redundancy (lrMinThroughput parameter) on an LACP channel, you must set the throughput parameter to a value less than or equal to that of the lrMinThroughput parameter.



The maximum supported throughput of an LACP channel is calculated as the maximum supported throughput of the active subchannel.

If the throughput parameter value is equal to or less than the lrminthroughput parameter value, HA failover occurs when both of the following conditions exist at the same time:

- None of the subchannels' maximum supported throughput meet the lrMinThroughput parameter value.
- The maximum supported throughput of the LACP channel does not meet the throughput parameter value

Consider an example of an HA setup that has Citrix ADCs NS1 and NS2, with switches SW1 and SW2. NS1 is connected to NS2 through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000 Mbps.

Following are the LACP-parameter settings in this example:

Parameter	Value
Throughput	2000

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Parameter	Value
lrminthroughput	2000

NS1 forms two subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2). Each of the two subchannels supports a maximum throughput of 2000 Mbps. Applying an algorithm, NS1 makes one subchannel (say subchannel 1) active and the other standby.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over. HA failover does not occur, because the maximum supported throughput of the LACP channel is not less than the throughput parameter value:

Maximum supported throughput of the LACP channel = Maximum supported throughput of the active channel = Maximum supported throughput of subchannel 2 = 2000 Mbps

If subchannel 2's maximum supported throughput also falls below the lrminthroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps), HA failover occurs, because the maximum supported throughput of the LACP channel is then less than the throughput parameter value:

Configure Link Redundancy using LACP channels

To configure link redundancy for a LACP channel by using the CLI:

At the command prompt, type the following commands to configure the channel and verify the configuration:

- **set channel** <id> -lrMinThroughput <positive_integer>
- **show channel**

Example:

```
1 > set channel la/1 – lrMinThroughput  2000
2 Done
3 > set channel la/2 – throughput 2000 – lrMinThroughput  2000
4 Done
```

To configure link redundancy for a LACP channel by using GUI

1. Navigate to System > Network > Channels.
2. In the details pane, select an LACP channel for which you want to configure link redundancy, and then click Edit.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. In the Configure LACP channel dialog box, set the lrMinThroughput parameter.
4. Click Close.

Redundant Interface Set

May 22, 2023

> **Note**
>
> Link redundancy configuration is not supported on a Citrix VPX instance hosted on a Citrix SDX appliance.

A redundant interface set is a set of interfaces where one of the interfaces is active and the remaining ones are standby. If the active interface fails, one of the standby interfaces takes over and becomes active.

The following are the main benefits of using redundant interface sets:

- A redundant interface set ensures connection reliability between the Citrix ADC appliance and a peer device by providing back up links between them.
- Unlike link redundancy using LACP, no configuration is required on the peer device for a redundant interface set. To the peer device, redundant interface set appear as individual interfaces and not as a set or collection.
- In an high availability configuration (HA), redundant interface sets can minimize the number the HA failovers.

> **Note**
>
> Redundant Interface Set was formerly known as 'NIC bundling'when first introduced in 10.5 release.

How Redundant Interface Set Works

For a redundant interface set, the Citrix ADC appliance derives a MAC address on the basis of an internal algorithm and assigns it to the redundant interface set. This MAC address is shared by all the member interfaces and is used only by the active interface at a time. The active interface broadcasts GARP messages, which contains the MAC address assigned to the redundant interface set and not the interface's own physical MAC address. When the current active interface fails and is taken over by another interface, the new active interface sends GARP messages. The peer device updates its forwarding table with the new active interface information. The standby interfaces do not send any GARP messages. The standby interfaces do not send any packets and they drop any packets they receive.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

In a redundant interface set, selection of the member interface as active is based on either of the following factors:

- **Redundant interface priority**. This is a parameter of an interface and it defines the priority of the interface in a redundant interface set for the active member selection. This parameter specifies a positive integer. Lower the value higher the priority of active member selection. The member interface with the highest priority (lowest value) is selected as the active interface of the redundant interface set.
- **Binding order of the member interfaces**. If all the member interfaces have the same redundant interface priority, the member interface that was bound first to the redundant interface set is selected as the active interface of the redundant interface set.

In a redundant interface set, active interface selection is triggered in one of the following events:

- When the current active interface fails or you disable it.
- When you set the priority of a standby interface to a value lower than that of the current active interface. The standby interface takes over as the active interface.
- When you bind an interface whose priority is lower than that of the current active interface. The newly bound interface takes over as the active interface.

Points to Consider for Configuring Redundant Interface Sets

Consider the following points before you configure a redundant interface set:

- In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.
- In a high availability configuration, redundant interface set configurations do not propagate or synchronize to the secondary node.
- You can configure a maximum of four redundant interface sets on a Citrix ADC appliance.
- You can bind a maximum of 16 interfaces to a redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to another redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to a link aggregate (LA) channel.
- LA channels cannot be bound to a redundant interface set.
- Redundant interface sets cannot be bound to an LA channel.
- In a cluster setup:
  - Redundant interface sets cannot be bound to a cluster link aggregation.
  - A link redundant set is specified in N/LR/X notation (for example, 1/LR/3). Where:
    N is the ID of the cluster node on which the redundant interface set is to be created.
    X is a link-redundant set identifier on a cluster node. X can range from 1-4.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- A cluster link aggregation cannot be bound to a redundant interface set.
- A redundant interface set can include only the interfaces of the node to which the redundant interface set belongs.
- An Existing elink redundancy set configuration on a standalone appliance automatically changes to cluster notation (N/LR/X) after the appliance is added to a cluster setup.

Configuration Steps

Configuring redundant interface set on a Citrix ADC appliance consists of the following tasks:

- **Create a redundant interface set**. Use the channel command operation for creating a redundant interface set.

  In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

  In a cluster setup, a link redundant set is specified in N/LR/X (for example, 1/LR/3), where: N is the ID of the cluster node on which the redundant interface set is to be created, X is link redundant set identifier on a cluster node. X can range from 1-4.

- **Bind interfaces to the redundant interface set**. Associate the desired interfaces with the redundant interface set. An interface cannot be a part of multiple redundant interface sets.
- **(Optional) Set a redundant interface priority on the member interface**. Use the interface command operation for setting the redundant interface priority on a desired member interface of a redundant interface set.

To create a redundant interface set by using the CLI:

At the command prompt:

- add channel <ID>
- show channel <ID>

To bind interfaces to a redundant interface set by using the CLI:

At the command prompt:

- bind channel <ID> <ifnum>
- show channel <ID>

To set a redundant interface priority of an interface by using the CLI:

At the command prompt:

- set interface <ID> -lrsetpriority <positive_integer>
- show interface <ID>

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Sample configuration 1:

In the following example, redundant interface set LR/1 is created, and interfaces 1/1, 1/2, 1/3, and 1/4 are bound to LR/1. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command displays that the interface 1/1 is the current active interface for the redundant interface set lr/1.

```
> add channel lr/1
 Done
> bind channel lr/1 1/1 1/2 1/3 1/4
 Done
> show channel
1)    Interface LR/1 (Link Redundant) #23
        flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
        MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s

                   Inactive Member
                1/3: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Inactive Member
                1/4: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                   Inactive Member
Done
```

Sample configuration 2:

In the following example, redundant interface priority of the member interface 1/4 is set to 100, which is lower than the set redundant interface priority of all the other member interfaces of LR/1.

Output of the show channel command displays that the interface 1/4 is the current active interface for the redundant interface set LR/1.

```
> set interface 1/4 -lrsetPriority 100
Done
> show channel
1)      Interface LR/1 (Link Redundant) #23
        flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
        MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
        Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
                 throughput 0
        Actual: throughput 1000
        LLDP Mode: NONE,
        RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
12          TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
13          NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
14          Bandwidth thresholds are not set.
15                  1/1: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                       Inactive Member
16                  1/2: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                       Inactive Member
17                  1/3: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                       Inactive Member
18                  1/4: UTP-1000-FULL-OFF          UP  0h14m06s    LR
                       Active Member
19  Done
```

Sample configuration 3:

Consider a cluster setup of four nodes N1, N2, N3, and N4. In this example, redundant interface set 1/LR/3 is created on node N1, and interfaces 1/1/1, 1/1/2, and 1/1/3 are bound to it. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command indicates that interface 1/1/1 is the current active interface for redundant interface set 1/LR/3.

```
1       > add channel 1/LR/3
2
3       Done
4       > bind channel 1/LR/3 1/1/1 1/1/2 1/1/3
5
6       Done
7       > show channel
8       1)    Interface 1/LR/3 (Link Redundant) #14
9               flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON,
                   802.1q>
10              MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0
                   h00m00s
11              Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
12              throughput 0
13              Actual: throughput 1000
14              LLDP Mode: NONE,
15              RX: Pkts(66) Bytes(4406) Errs(0) Drops(82) Stalls(0)
16              TX: Pkts(55) Bytes(2626) Errs(0) Drops(145) Stalls(0)
17              NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted
                   (0)
18              Bandwidth thresholds are not set.

Binding an SNIP address to an Interface

September 14, 2021

You can now bind a Citrix ADC owned SNIP address to an interface without using Layer 3 VLANs. Any packets related to the SNIP address will go only through the bound interface.

This feature can be useful in a scenario where the upstream switch does not support Link Aggregation channels and you want the Citrix ADC appliance to load balance traffic, originated from a server, across the four links to the upstream switch as shown in the following illustration.

The following tables describe the example settings for the scenario:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity	Name	Value
SNIP addresses on NS1	SNIP2 (for reference purpose only)	10.10.10.2
		SNIP3 (for reference purpose only) SNIP4 (for reference purpose only) SNIP5 (for reference purpose only)
LLB virtual server on NS1	LLB_VSERVER1	-
Transparent monitor on NS1	TRANS_MON	-
LLB services on NS1	LLB_SVC2	10.10.10.240
		LLB_SVC3
		LLB_SVC4
		LLB_SVC5
MAC address of interface 1/2 on NS1	NS_MAC_2 (for reference purpose only)	00:e0:ed:0f:bc:e0
MAC address of interface 1/3 on NS1	NS_MAC_3 (for reference purpose only)	00:e0:ed:0f:bc:df
MAC address of interface 1/4 on NS1	NS_MAC_4 (for reference purpose only)	00:e0:ed:0f:bc:de
MAC address of interface 1/5 on NS1	NS_MAC_5 (for reference purpose only)	00:e0:ed:1c:89:53
IP address of Router R1	Router_IP (for reference purpose only)	10.10.10.1
MAC address of interface of R1	ROUTER_MAC1 (for reference purpose only)	00:21:a1:2d:db:cc

To configure the example settings:

1. Add four different SNIPs in different subnet ranges. This is for ARP to be resolved on four different links. For more information on creating a SNIP address, see Configuring Subnet IP Addresses (SNIPs).

   CLI example:

```
1 > add ns ip 10.10.10.2 255.255.255.0 -type SNIP
2  Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> add ns ip 10.10.10.3 255.255.255.128 –type SNIP
Done
> add ns ip 10.10.10.4 255.255.255.192 –type SNIP
Done
> add ns ip 10.10.10.5 255.255.255.224 –type SNIP
Done
```

2. Add four different dummy services in the added SNIP subnets. This is to ensure that the traffic is sent out with source IP as one of the four configured SNIPs. For more information on creating a service, see Set up basic load balancing.

   CLI example:

```
> add service LLB_SVC2 10.10.10.240 any *
 Done
> add service LLB_SVC3 10.10.10.120 any *
 Done
> add service LLB_SVC4 10.10.10.60 any *
 Done
> add service LLB_SVC5 10.10.10.30 any *
 Done
```

3. Add a transparent ping monitor for monitoring the gateway. Bind the monitor to each of the configured dummy services. This is to make the state of the services as UP. For more information on creating a transparent monitor, see Configure monitors in a load balancing setup.

   CLI example:

```
> add monitor TRANS_MON ping -destIP 10.10.10.1 -transparent YES
 Done
> bind monitor TRANS_MON LLB_SVC2
 Done
> bind monitor TRANS_MON LLB_SVC3
 Done
> bind monitor TRANS_MON LLB_SVC4
 Done
> bind monitor TRANS_MON LLB_SVC5
 Done
```

4. Add a link load balancing (LLB) virtual server and bind the dummy services to it. For more information on creating an LLB virtual server, see Configuring a Basic LLB Setup.

   CLI example:

```
> add lb vserver LLB_VSERVER1 any
 Done
> set lb vserver LLB_VSERVER1 -lbmethod ROUNDROBIN
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
```

5. Add the LLB virtual server as the default LLB route. For more information on creating an LLB route see Configuring a Basic LLB Setup.

   CLI example:

```
> add lb route 0.0.0.0 0.0.0.0  LLB_VSERVER1
 Done
```

6. Add an ARP entry for each of the dummy services with the MAC address of the gateway. This way the gateway is reachable through these dummy services. For more information on adding an ARP entry, see Configuring Static ARP.

   CLI example:

```
> add arp -ipaddress 10.10.10.240 -mac 00:21:a1:2d:db:cc -ifnum
   1/2
 Done
> add arp -ipaddress 10.10.10.120 -mac 00:21:a1:2d:db:cc -ifnum
   1/3
 Done
> add arp -ipaddress 10.10.10.60 -mac 00:21:a1:2d:db:cc -ifnum 1/4
 Done
> add arp -ipaddress 10.10.10.30 -mac 00:21:a1:2d:db:cc -ifnum 1/5
 Done
```

7. Bind a specific interface to an SNIP by adding an ARP entry for each of these SNIPs. This is to ensure that the response traffic will reach the same interface through which the request went out. For more information on adding an ARP entry, see Configuring Static ARP.

   CLI example:

```
> add arp -ipAddress 10.10.10.2 -mac 00:e0:ed:0f:bc:e0 -ifnum 1/2
 Done
> add arp -ipAddress 10.10.10.3 -mac 00:e0:ed:0f:bc:df -ifnum 1/3
 Done
> add arp -ipAddress 10.10.10.4 -mac 00:e0:ed:0f:bc:de -ifnum 1/4
 Done
> add arp -ipAddress 10.10.10.5 -mac 00:e0:ed:1c:89:53 -ifnum 1/5
 Done
```

Monitor the Bridge Table and Changing the Aging time

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Citrix ADC appliance bridges frames on the basis of bridge table lookup of the destination MAC address and the VLAN ID. However, the appliance performs forwarding only when Layer 2 mode is enabled.

The bridge table is dynamically generated, but you can display it, modify the aging time for the bridge table, and view bridging statistics. All the MAC entries in the bridge table are updated with the aging time.

To set the aging time of bridge table entries by using the CLI:

At the command prompt, type:

- **set l2param** -**bridgeagetimeout** <positive_integer>
- **show l2param**

Example:

```
> set l2param –bridgeagetimeout 90
 Done
```

To view the statistics of a bridge table by using the CLI:

At the command prompt, type:

- **stat bridge**

To set the aging time of bridge table entries by using the GUI:

Navigate to **System** > **Network**. On the **Network** page, in the **Settings** section, click **Configure Layer2 Parameters** and set the **Timeout Value For The Bridge Table Entries (seconds)** parameter.

To view the statistics of a bridge table by using the GUI:

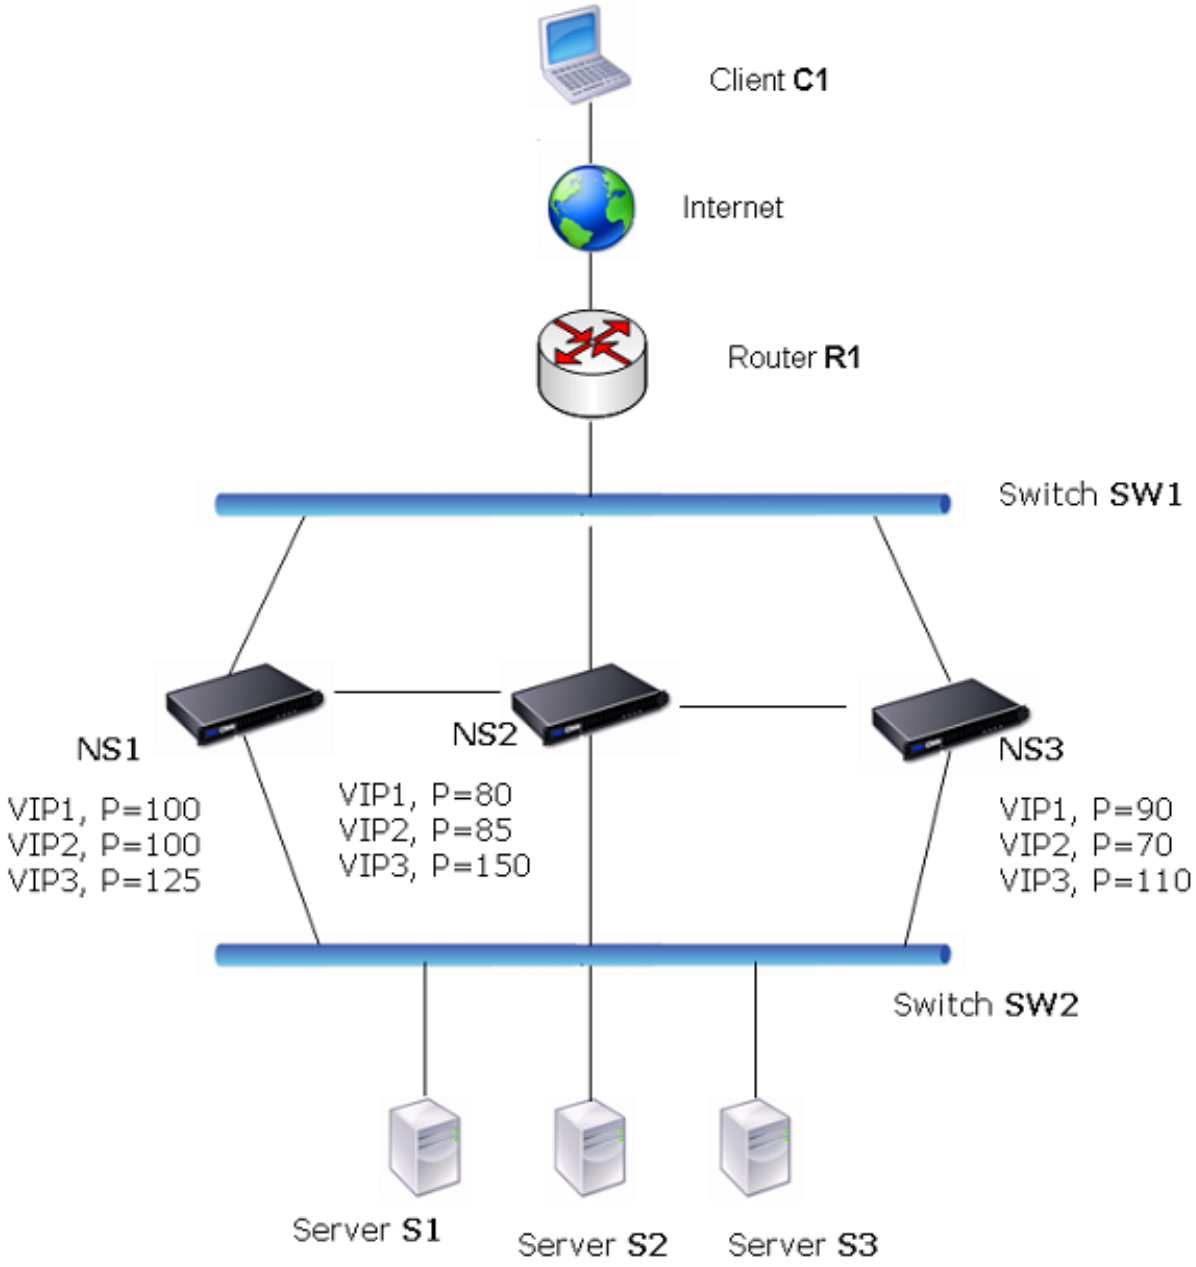
Navigate to **System** > **Network** > **Bridge Table**, select the MAC address, and click **Statistics**.

Citrix ADC Appliances in Active-Active Mode Using VRRP

September 14, 2021

An active-active deployment, in addition to preventing downtime, makes efficient use of all the Citrix ADC appliances in the deployment. In active-active deployment mode, the same VIPs are configured on all Citrix ADC appliances in the configuration, but with different priorities, so that a given VIP can be active on only one appliance at a time.

The active VIP is called the master VIP, and the corresponding VIPs on the other Citrix ADC appliances are called the backup VIPs. If a master VIP fails, the backup VIP with the highest priority takes over and becomes the master VIP. All the Citrix ADC appliances in an active-active deployment use the Virtual



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Router Redundancy Protocol (VRRP) protocol to advertise their VIPs and the corresponding priorities at regular intervals.

Citrix ADC appliances in active-active mode can be configured so that no Citrix ADC is idle. In this configuration, different sets of VIPs are active on each Citrix ADC. For example, in the following diagram, VIP1, VIP2, VIP3, and VIP4 are configured on appliances NS1, NS2, and NS3. Because of their priorities, VIP1 and VIP 2 are active on NS1, VIP3 is active on NS2 and VIP 4 is active on NS3. If, for example, NS1 fails, VIP1 on NS3 and VIP2 on NS2 become active.

Figure 1. An Active-Active Configuration

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The Citrix ADC appliances in the above diagram process traffic as follows:

1. Client C1 sends a request to VIP1. The request reaches R1.
2. R1 does not have an ARP entry for VIP1, so it broadcasts an ARP request for VIP1.
3. VIP1 is active in NS1, so NS1 replies with a source MAC address as the virtual MAC (for example virtual MAC1) associated with VIP1, and VIP1 as the source IP address.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table.
5. R1 updates the ARP entry with virtual MAC1 and VIP1.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

6. R1 forwards the packet to the VIP1 on NS1.
7. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP addresses and S2.
8. S2 replies to the SNIP on the Citrix ADC.
9. NS1 sends S2's reply to the client. In the reply, NS1 inserts MAC address of the physical interface as the source MAC address and VIP1 as the source IP address.
10. Should NS1 fail, the Citrix ADC appliances use the VRRP protocol to select the VIP1 with the highest priority. In this case, VIP1 on NS3 becomes active, and the following two steps update the active-active configuration.
11. NS3 broadcasts a GARP message for VIP1. In the message, virtual MAC1 is the source MAC address and VIP1 is the source IP address.
12. SW1 learns the new port for virtual MAC1 from the GARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS3. R1 updates its ARP table.

The priority of a VIP can be modified by health tracking. If you enable health tracking, you should make sure that preemption is also enabled, so that a VIP whose priority is lowered can be preempted by another VIP.

In some situations, traffic might reach a backup VIP. To avoid dropping such traffic, you can enable sharing, on a per-node basis, as you create an active-active configuration. Or you can enable the global send to master option. On a node on which sharing is enabled, it takes precedence over send to master.

Health Tracking

Base priority (BP-range 1-255) ordinarily determines which VIP is the master VIP, but effective priority (EP) can also affect the determination.

For example, if a VIP on NS1 has a priority of 101 and same VIP on NS2 has a priority of 99, the VIP on NS1 is active. However, if two vservers are using the VIP on NS1 and one of them goes DOWN, health tracking can reduce the EP of VIP on NS1. VRRP then makes the VIP on NS2 the active VIP.

Following are the health tracking options for modifying EP:

- **NONE.** No tracking. EP = BP
- **ALL.** If all virtual servers are UP, then EP = BP. Otherwise, EP = 0.
- **ONE.** If at least one virtual server is UP, then EP = BP. Otherwise, EP = 0.
- **PROGRESSIVE.** If ALL virtual servers are UP, then EP = BP. If ALL virtual servers are DOWN then EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP and k is the number of virtual servers that are down.

Note: If you specify a value other than NONE, preemption should be enabled, so that the backup VIP with the highest priority becomes active if the priority of the master VIP is downgraded.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Preemption

Preemption of an active VIP by another VIP that attains a higher priority is enabled by default, and normally should be enabled. In some cases, however, you may want to disable it. Preemption is a per-node setting for each VIP.

Preemption can occur in the following situations:

- An active VIP goes down and a VIP with a lower priority takes its place. If the VIP with the higher priority comes back online, it preempts the currently active VIP.
- Health tracking causes the priority of a backup VIP to become higher than that of the active VIP. The backup VIP then preempts the active VIP.

Sharing

In the event that traffic reaches a backup VIP, the traffic is dropped unless the sharing option is enabled on the backup VIP. This behavior is a per node setting for each VIP and is disabled by default.

In the figure **An Active-Active Configuration** VIP1 on NS1 is active and VIP1 VIPs on NS2 and NS3 are backups. Under certain circumstances, traffic may reach VIP1 on NS2. If Sharing is enabled on NS2, this traffic is processed instead of dropped.

Configuring Active-Active Mode

September 14, 2021

On each Citrix ADC appliance that you want to deploy in active-active mode, you must add a virtual MAC and bind the virtual MAC to a VIP. The virtual MAC for a given VIP must be same on each appliance. For example, if VIP 10.102.29.5, is created on the appliances, a virtual router ID (VRID) must be created on each Citrix ADC and bound to VIP 10.102.29.5 on each Citrix ADC. When you bind a virtual MAC to a VIP, the appliance sends VRRP advertisements to each VLAN that is bound to that VIP. The virtual MAC can be shared by different VIPs configured on the same Citrix ADC.

Configuring IPv4 Active-Active Mode

Perform the following tasks on each of the Citrix ADC appliances to be included in the active-active configuration:

- **Add a virtual MAC address**. Add a virtual MAC address by adding a VRID. You can also specify a priority and enable or disable preemption and sharing on this VRID address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Add a VIP address and associate the virtual MAC's VRID**. Add a VIP address and set the VRID parameter to the newly created VRID. The attributes of the VRID (for example, priority and preemption) are bound to this VIP address.
  Note: The same VIP address must be added to all the other Citrix ADC appliances.

To add a virtual MAC address by using the CLI

At the command prompt, type:

- **add vrID** <id> [-**priority** <positive_integer>] [-**preemption** (**ENABLED**|**DISABLED**)][-**sharing** (**ENABLED**|**DISABLED**)] [-**tracking** <tracking>]
- **show vrid**

To add a VIP address by using the CLI:

At the command prompt, type:

- **add ns ip** <IPv4Address> -type VIP -vrid <value>
- **show ns ip**

To configure a virtual MAC by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**, on the **VMAC** tab, add a new virtual MAC, or edit an existing virtual MAC.
2. Set the following parameters:
   - Virtual Router ID
   - Priority
   - Tracking
   - Preemption
   - Sharing

To configure a VIP address and associate the VRID to it by using the GUI:

1. Navigate to **System** > **Network** > **IPs**, on the **IPV4s** tab, add an IP address of type VIP.
2. While adding the IP address, select the virtual router ID from the **Virtual Router Id** drop down box.

Sample Configuration:

The following sample configuration is for deploying Citrix ADC appliances NS1 and NS2 in IPv4 active-active mode. VIP address 203.0.113.10 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP address is bound to a virtual MAC address. 203.0.113.10 is master on NS2, because its priority (200) on NS2 is higher than on NS1 (100).

```
1     Settings on NS1
2
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> add vrid 10 –Priority 100 –Preemption Enabled –sharing Enabled

Done

> add ns ip 203.0.113.10 –type VIP –vrid 10

Done

Settings on NS2

> add vrid 10 –Priority 200 –Preemption Enabled –sharing Enabled

Done

> add ns ip 203.0.113.10 –type VIP –vrid 10

Done
```

Configuring IPv6 Active-Active Mode

Perform the following tasks on each of the Citrix ADC appliances to be included in the active-active configuration:

- **Add a virtual MAC6 address**. Add a virtual MAC6 address by adding a VRID6. You can also specify a priority and enable or disable preemption and sharing on this VRID6 address.
- **Add a VIP6 address**. Add a VIP6 address. Set the VRID6 parameter to the VRID6 of the newly created virtual MAC6.The attributes of the virtual MAC6 (for example, priority and preemption) are bound to this VIP6 address.
  Note: The same VIP6 address must be added to all the other Citrix ADC appliances.

To add a virtual MAC6 address by using the CLI:

At the command prompt, type:

- **add vrID6** <id> [-**priority** <positive_integer>] [-**preemption** (**ENABLED** | **DISABLED**)] [-**sharing** (**ENABLED** | **DISABLED**)]
- **show vrID6**

To add a VIP6 address by using the CLI:

At the command prompt, type:

- **add ns ip6** <IPv6Address> -**type** VIP -**vrid** <value>
- **show ns ip6**

To configure a virtual MAC6 by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Navigate to **System** > **Network** > **VMAC**, on the **VMAC6** tab, add a new virtual MAC6, or edit an existing **VMAC6**.
2. Set the following parameters:

    - Virtual Router ID
    - Priority
    - Preemption
    - Sharing

To configure a VIP6 address and associate the VRID to it by using the GUI:

1. Navigate to **System** > **Network** > **IPs**, on the **IPV6s** tab, add an IPv6 address of type VIP.
2. While adding the VIP6 address, select the VRID6 from the **Virtual Router Id** drop down box.

Sample Configuration:

The following sample configuration is for deploying Citrix ADC appliances NS1 and NS2 in IPv6 active-active mode. VIP6 address 2001:db8::5001 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP6 address is bound to a virtual MAC6 address. 2001:db8::5001 is master on NS2, because it's priority (200) on NS2 is higher than on NS1 (100).

```
Settings on NS1
> add vrid6 10 -Priority 100 -Preemption Enable -sharing Enable

Done
> add ns ip6 2001:db8::5001 -type VIP -vrid6 10

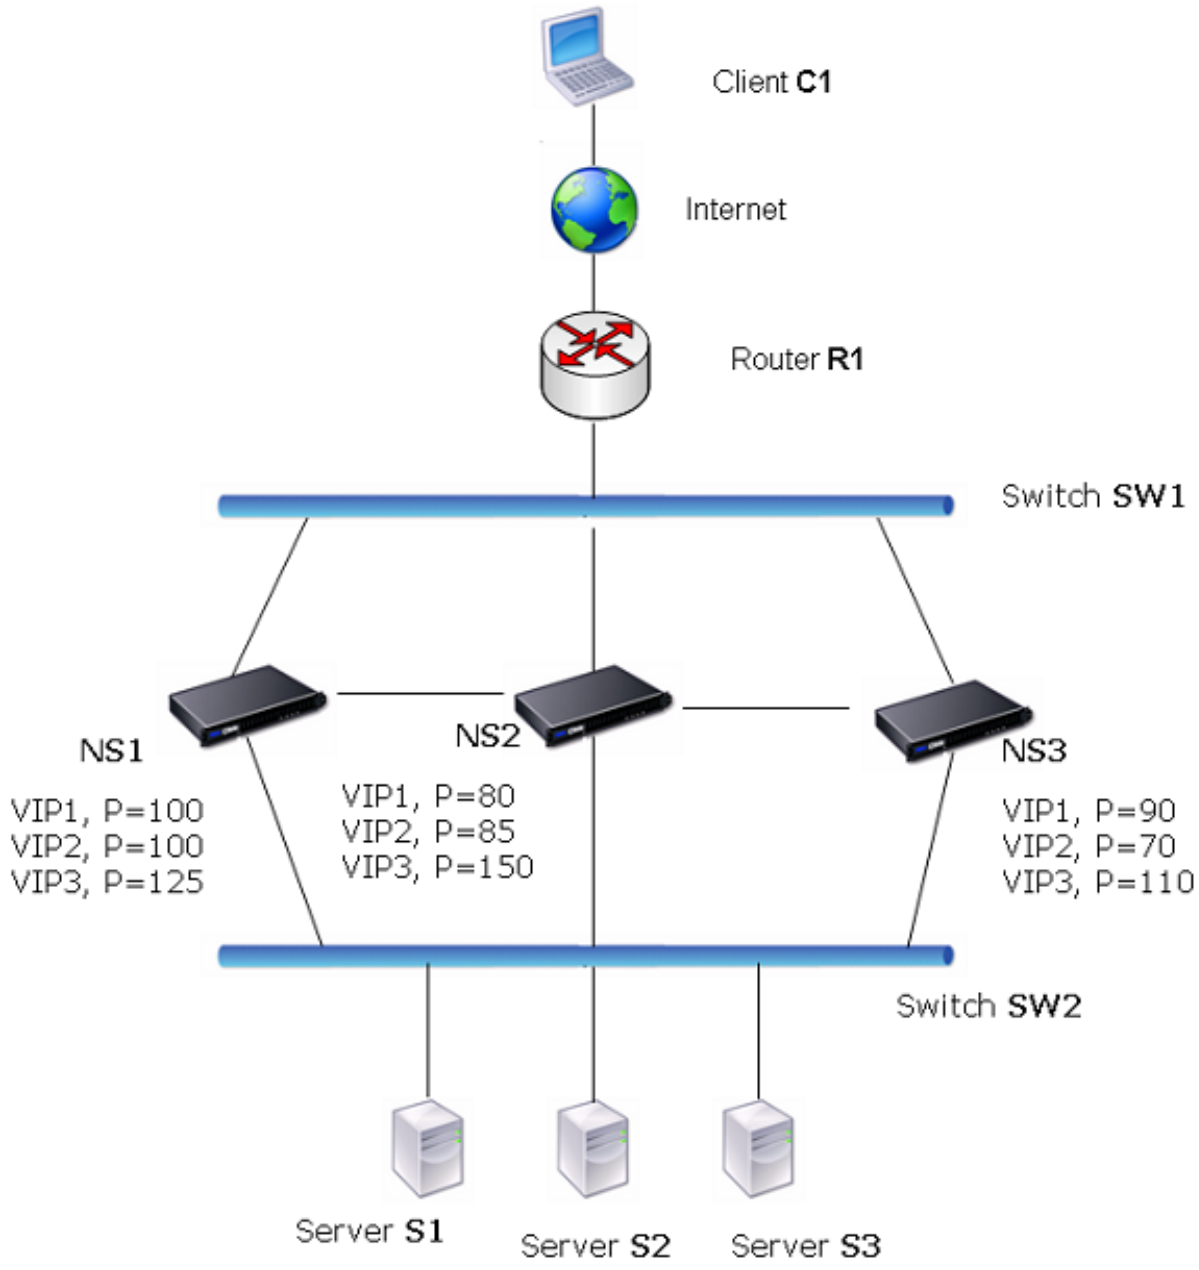
Done
Settings on NS2
> add vrid6 10 -Priority 200 -Preemption Enable -sharing Enable

Done
> add ns ip6 2001:db8::5001 -type VIP -vrid6 10

Done
```

Configuring Send to Master

September 14, 2021



Usually, the traffic destined to a VIP reaches the Citrix ADC appliance on which the VIP is active, because an ARP request with the VIP and a virtual MAC on that appliance has reached the upstream router. But in some cases, such as static routes configured on the upstream router for the VIP subnet, or a topology that blocks this route, the traffic can reach a Citrix ADC appliance on which the VIP is in backup state. If you want this appliance to forward the data packets to the appliance on which the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

VIP is active, you need to enable the send to master option. This behavior is a per node setting and is disabled by default.

For example, in the following diagram, VIP1 is configured on NS1, NS2, and NS3 and is active on NS1. Under certain circumstances, traffic for VIP1 (active on NS1) may reach VIP1 on NS3. When the send to master option is enabled on NS3, NS3 forwards the traffic to NS1 through NS2 by using route entries for NS1.

Figure 1. An Active-Active Configuration with Send to Master Option Enabled

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable send to master by using the CLI:

At the command prompt, type:

set vrIDParam -**sendToMaster** (**ENABLED** **DISABLED**)

Example:

```
> set vrIDParam -sendToMaster ENABLED
 Done
```

To enable send to master by using the GUI:

1. Navigate to **System** > **Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. Select the **Send to Master** option.

Configuring VRRP Communication Intervals

September 14, 2021

In an active-active deployment, all Citrix ADC nodes use the Virtual Router Redundancy Protocol (VRRP) to advertise their master VIP addresses and the corresponding priorities in VRRP advertisement packets (hello messages) at regular intervals.

VRRP uses the following communication intervals:

- **Hello Interval**. Interval between the VRRP hello messages that a node of a master VIP address sends to its peer nodes.
- **Dead Interval**. Time after which a node of a backup VIP address considers the state of the master VIP address as DOWN if VRRP hello messages are not received from the node of the master VIP address. After the dead interval, the backup VIP address takes over and becomes the master VIP address.

You can change these intervals to a desired value. Both of these communication intervals are per node setting for all VIP addresses in that node.

To configure VRRP communication intervals by using the CLI:

At the command prompt, type:

- **set vrIDParam** [-**helloInterval** <msecs>] [-**deadInterval** <secs>]
- **sh vrIDParam**

Example:

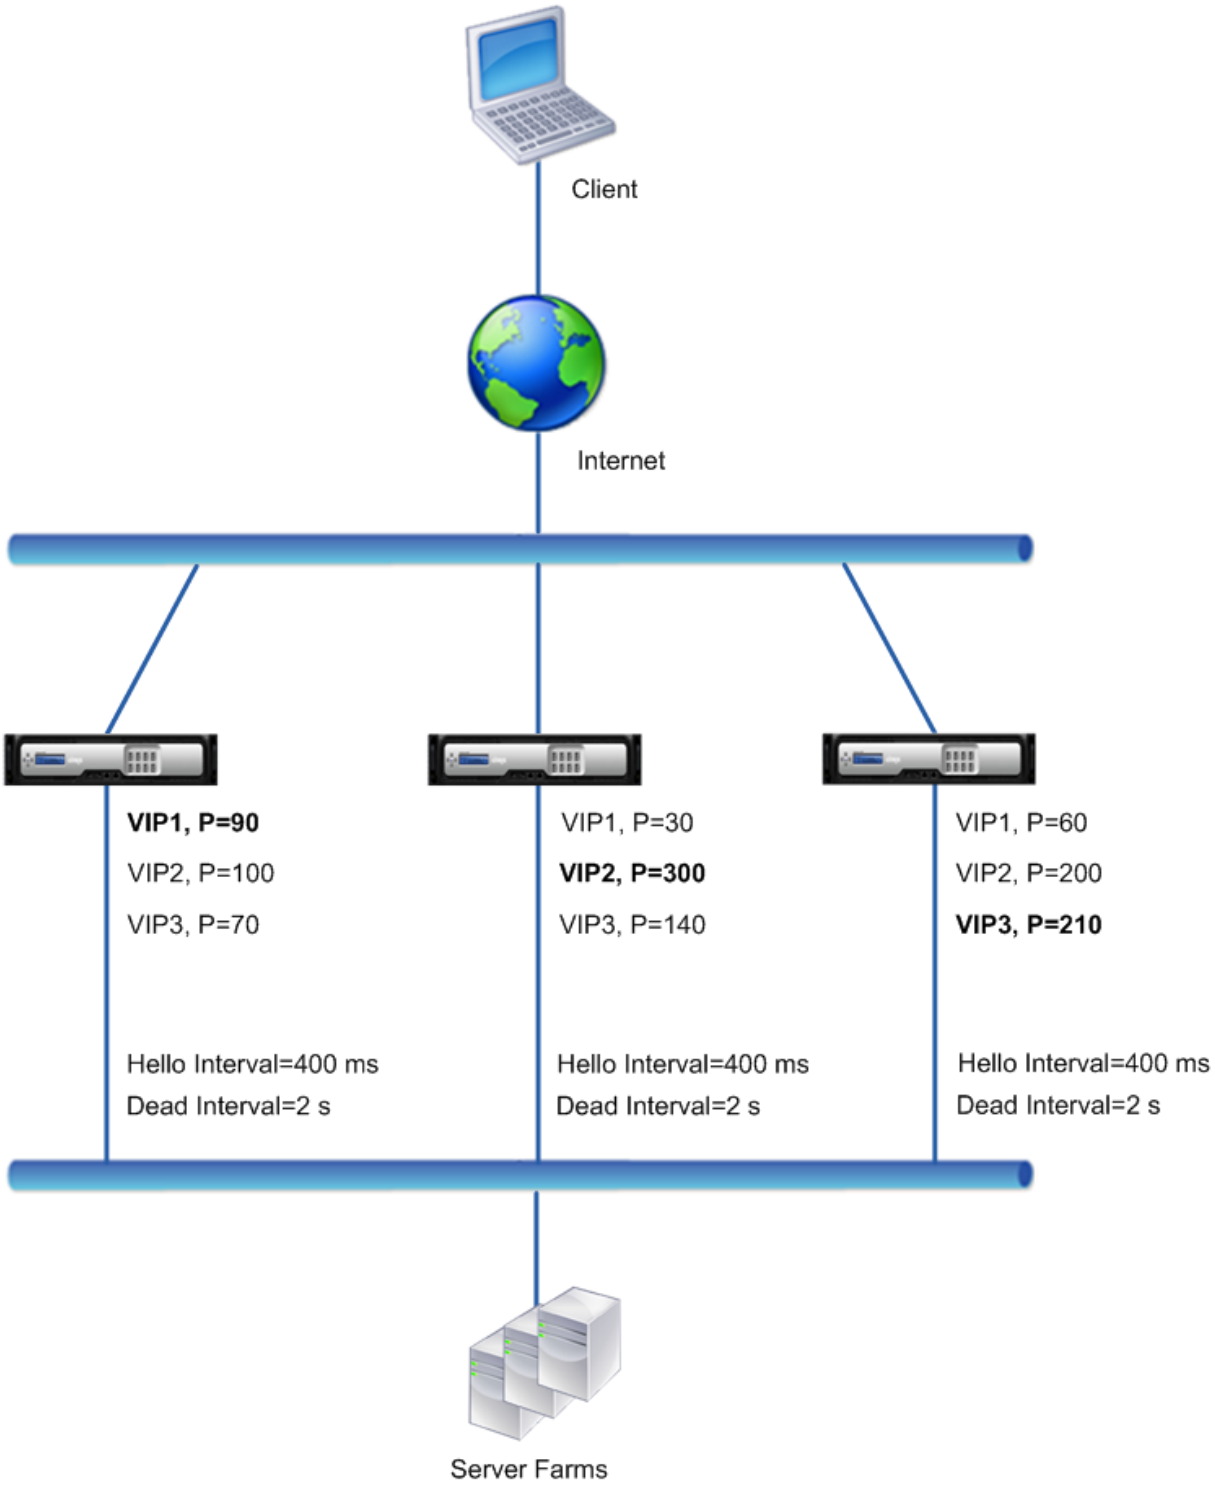
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> set vrIDParam -helloInterval 500 -deadInterval 2
 Done
```

To configure VRRP communication intervals by using the GUI:

1. Navigate to **System** > **Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. In **Configure Virtual Router Parameter**, set the **Hello Interval** and **Dead Interval** parameters.
3. Click **OK**.

Example 1: Nodes with the Same VRRP Dead Intervals



Consider an active-active deployment consisting of Citrix ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3 are configured on each of these ADCs. Because of their priorities, VIP1 is active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

As shown in the table below, the dead interval is set to the same value (2 seconds) on all the three nodes. The VRRP communication intervals (hello interval and dead interval) of a node apply to all the VRIDs configured on the node, and in turn, apply to all VIP addresses associated with the VRIDs on the node.

On each node, the VIP addresses that are active (master) on that node use the hello interval, and the dead interval is used by the VIP addresses that are inactive (backup) on that node. Preemption is disabled for the VIP addresses in all the three nodes.

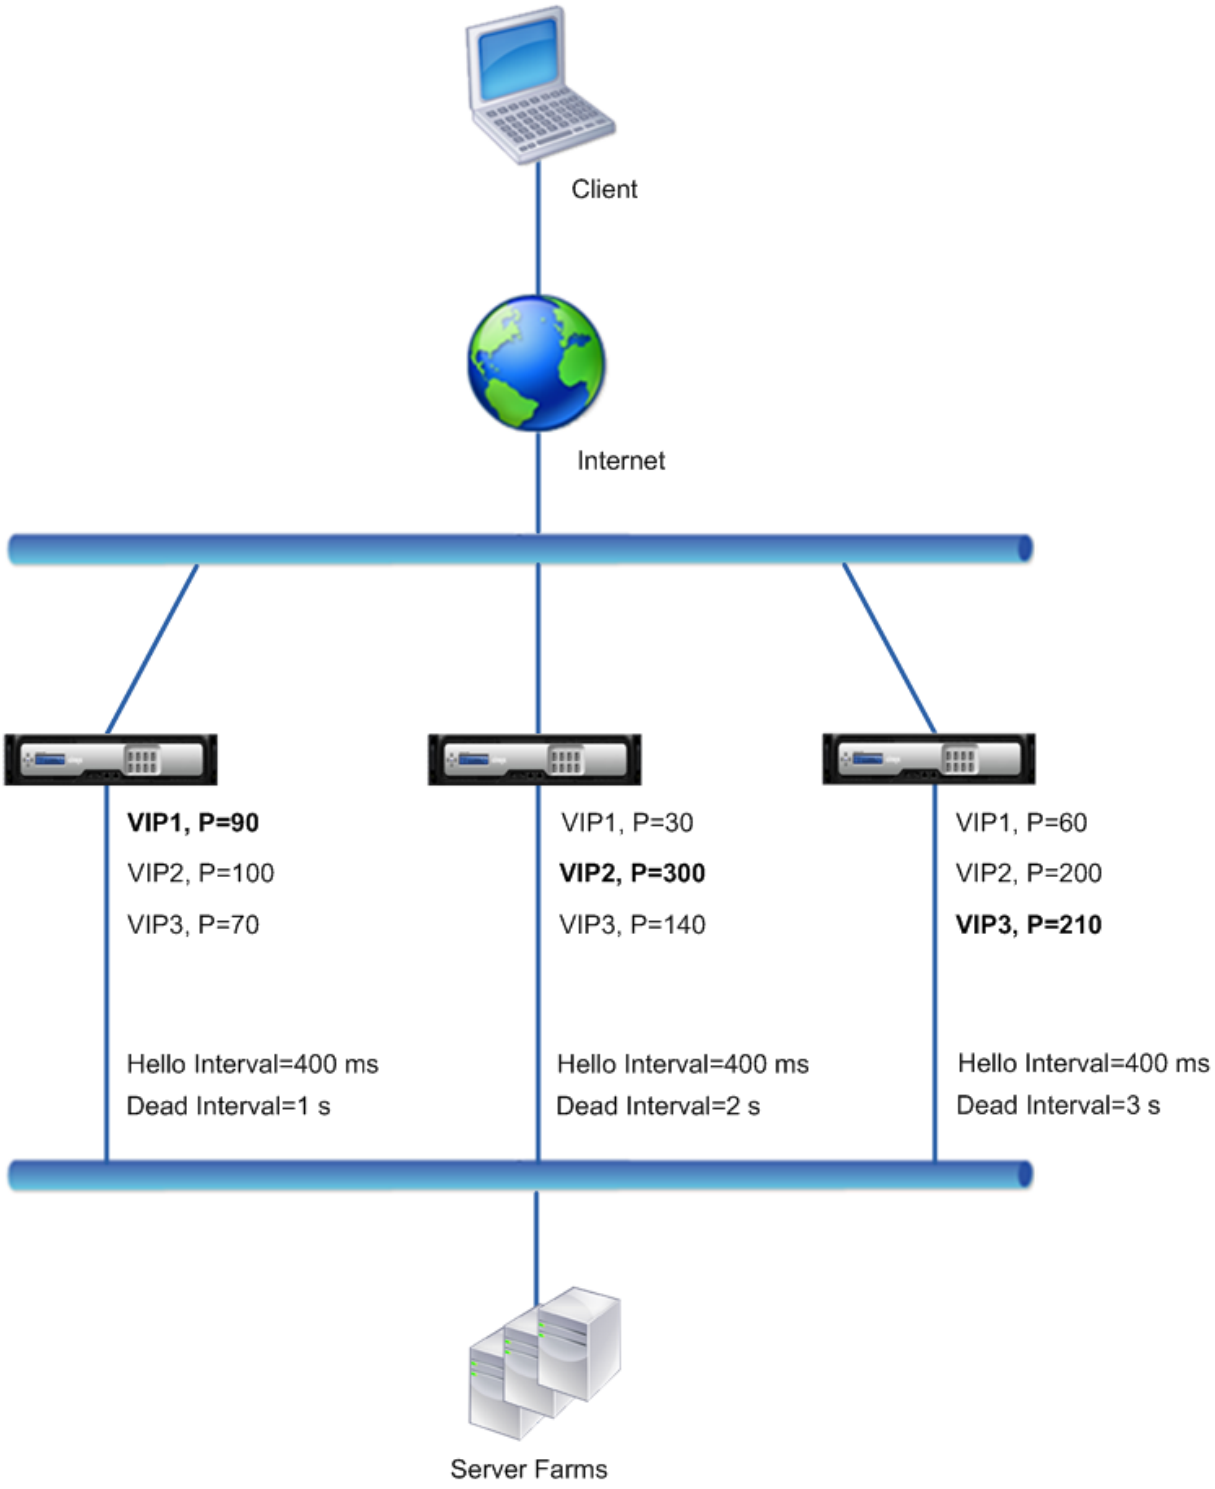
The following table lists the settings used in this example: VRRP interval example 1 settings.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The execution flow is as follows:

1. NS1 sends hello messages at a set hello interval of 400 ms to NS2 and NS3 for the VIP1 address, because VIP1 is active (the master) on NS1. Similarly, NS2 sends hello messages for VIP2, and NS3 sends hello messages for VIP3.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



2. On NS1, the set dead interval applies to VIP2 and VIP3, because they are inactive (backups) on NS1. Similarly, on NS2, the set dead interval applies to VIP1 and VIP3, and on NS3, the set dead interval applies to VIP1 and VIP2.
3. If NS1 goes down, NS2 and NS3 consider NS1 to be down if they receive no hello messages from NS1 for 2 seconds (the dead interval). VIP1 on NS3 takes over and becomes active (master) because its VRID priority (60) is higher than that of VIP1 of NS2 (30).

Example 2: Nodes with Different VRRP Dead Intervals

Consider a VRRP deployment similar to the deployment described in Example1 but with a different dead interval on each node (NS1, NS2, and NS3). Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: VRRP interval example 2 settings.

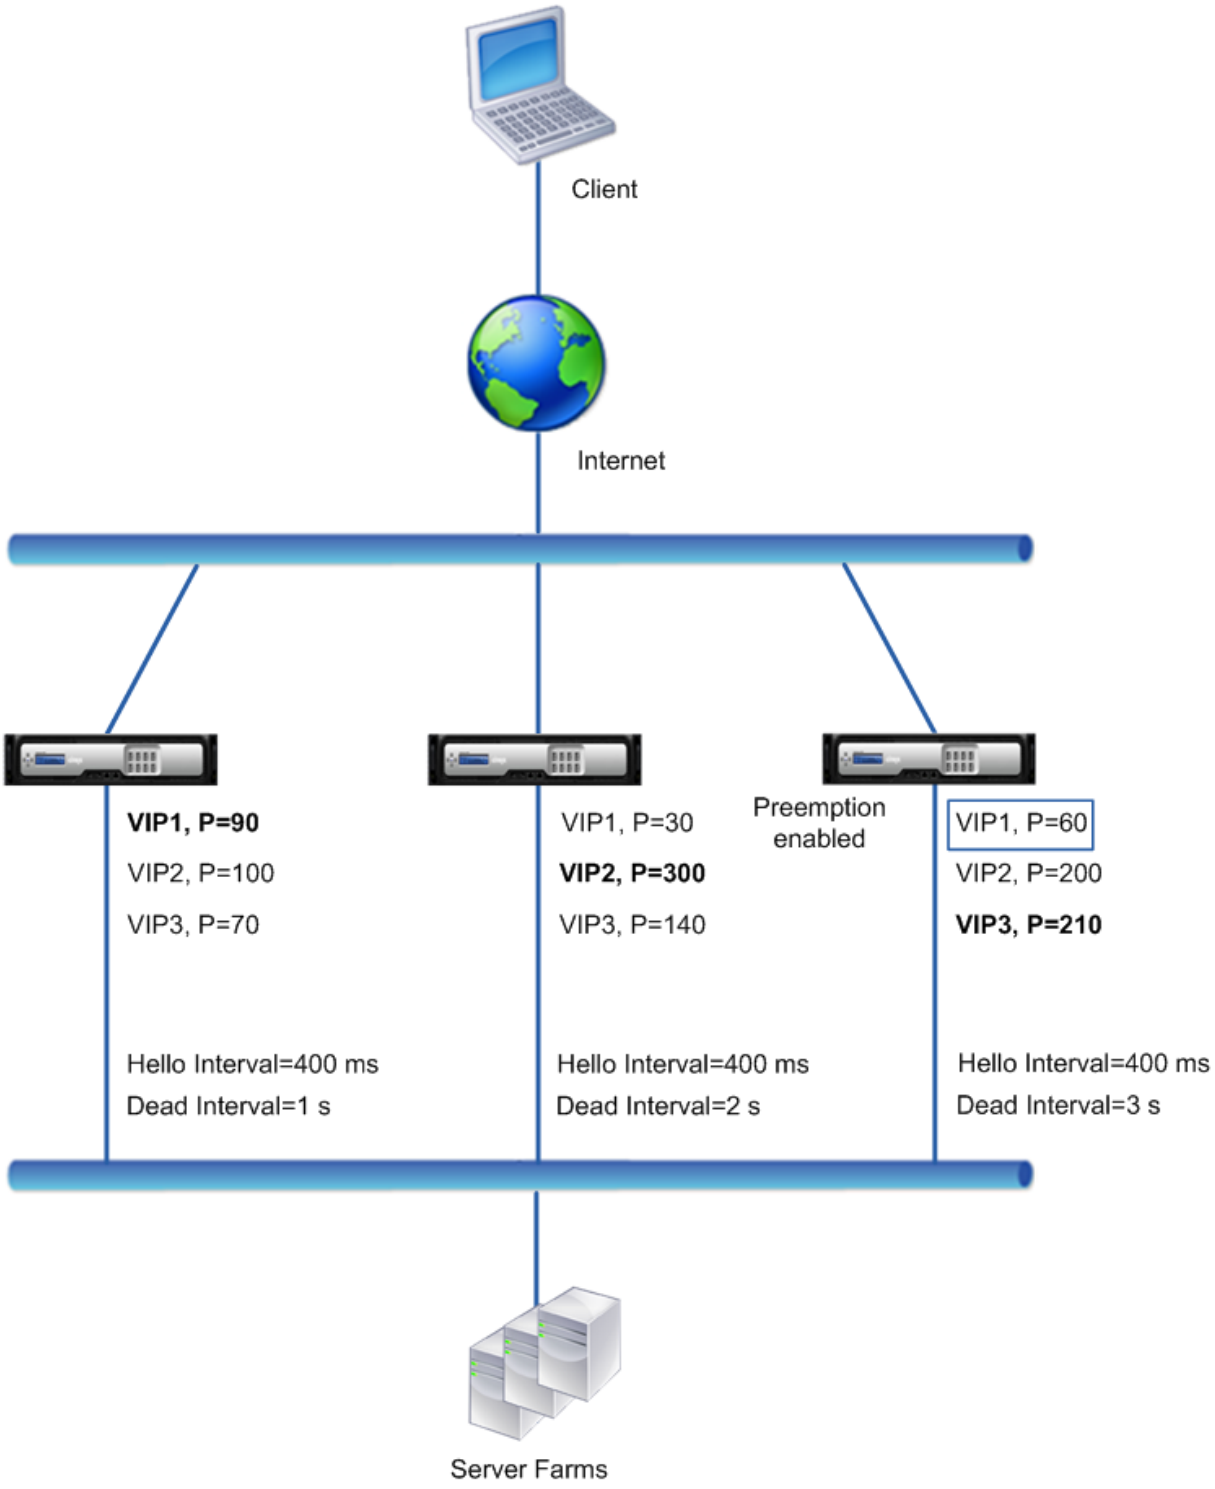
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's dead interval).
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

for VIP1.



Even though VIP1 on NS3 has a higher VRIP priority (60) than does VIP1 on NS2 (30), NS3's larger dead interval (3 seconds, vs. 2 seconds for NS2), prevents VIP1 on NS3 from taking over before VIP 1 on NS2 has already done so.

Example 3: Nodes with Different Dead Intervals and Preemption Enabled

Consider a VRRP deployment similar to the deployment described in Example1 but with different dead intervals on the three nodes, NS1, NS2, and NS3, and with preemption enabled for the VIP1 address on NS3.

The following table lists the settings used in this example: VRRP interval example 3 settings.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to down after not receiving any hello messages from NS1 for 2 seconds (NS2's set dead interval). At this time, NS3, with a dead interval of 3 seconds, does not consider NS1 to be down.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

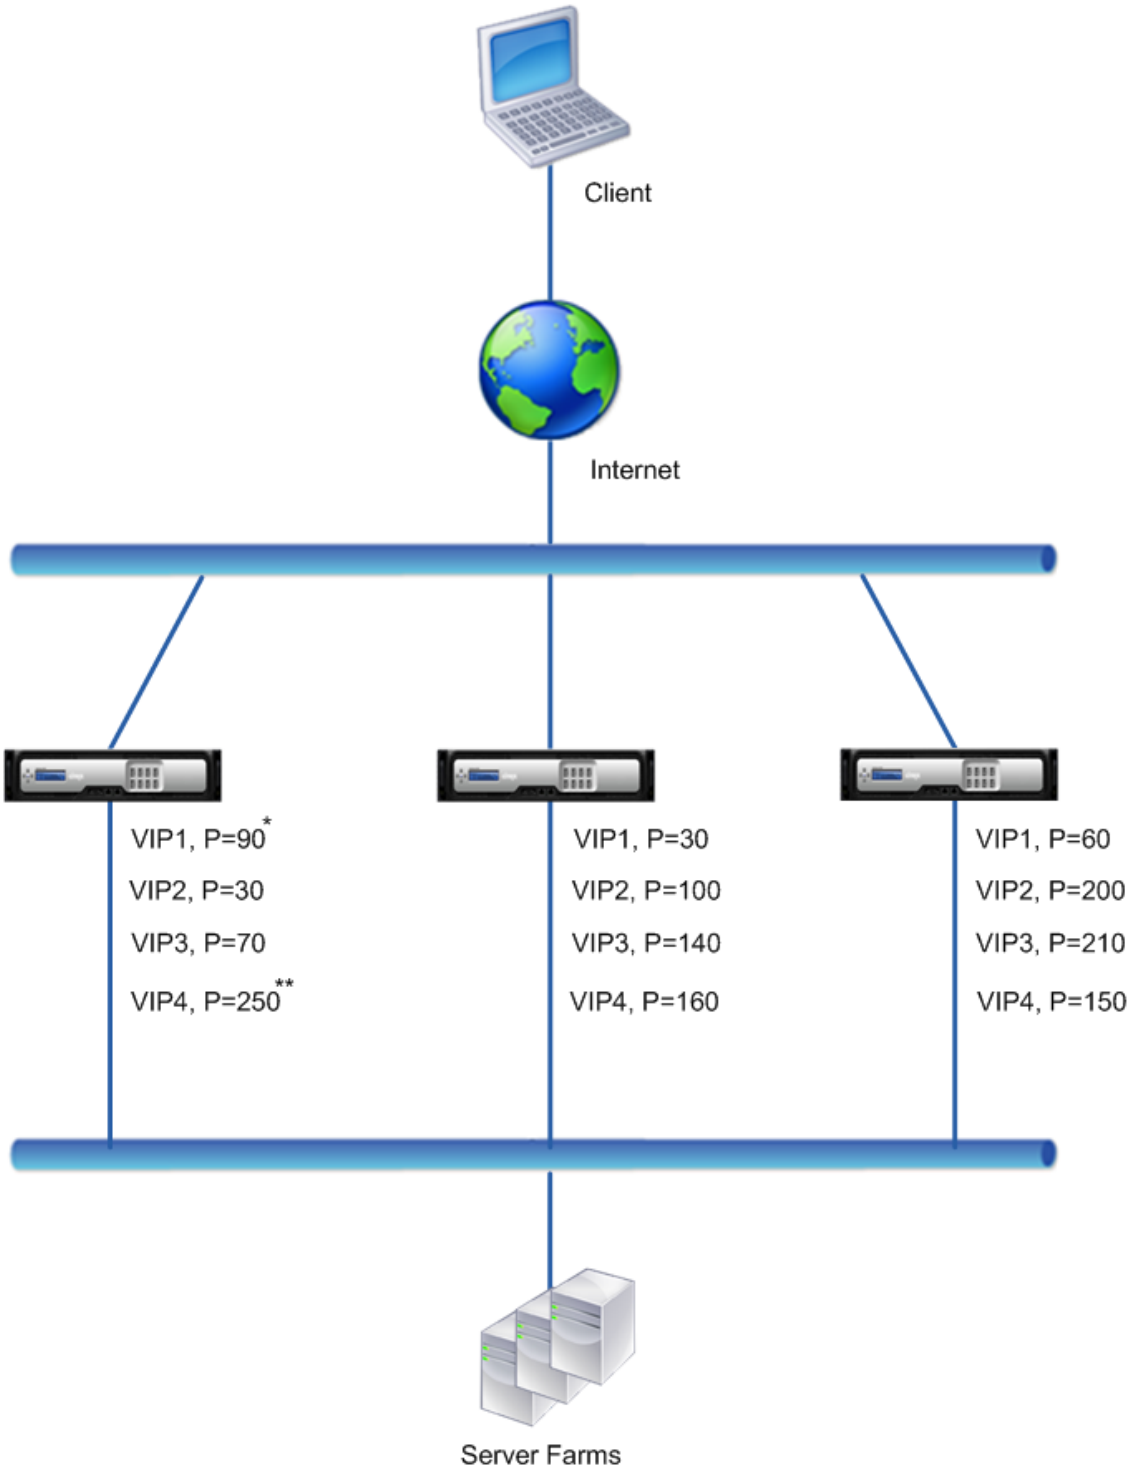
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.
3. Upon receiving hello messages from NS2 for VIP1, NS3 preempts NS2 for VIP1 because preemption is enabled for VIP1 of NS3 and the VRID priority (60) of VIP1 of NS3 is higher than that (30) of VIP1 of NS2.
4. VIP1 on NS3 takes over and becomes active (master). NS3 now starts sending hello messages for VIP1.

Configuring Health Tracking based on Interface State

September 14, 2021

To ensure that a backup VIP address takes over as the master VIP before the node of the current master VIP address goes down completely, you can configure a node to change the priority of a VIP address when the state of an interface on the node changes. For example, the node reduces the priority of a VIP address when the state of an interface changes to DOWN, and increases the priority when the state of the interface changes to UP. This feature is a per node configuration for each VIP address.

Example



Consider an active-active deployment consisting of Citrix ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3, and VIP4 are configured on each of these ADCs. Because of their priorities, VIP1 and VIP4 are active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

To ensure that the active VIP addresses on NS1 are taken over by either NS2 or NS3 before NS1 goes down completely, interface-based health tracking is configured for the VIP1 and VIP4 addresses on NS1. Configuring interface-based health tracking for a VIP address includes associating the desired interfaces and setting the reduced priority (trackifNumPriority) parameter for the associated VRID of the VIP address. For example, on NS1, interfaces 1/2, 1/3, and 1/5 are associated to the VRID of VIP1, and reduced priority is set to 20.

Preemption is enabled for these VIP addresses in all three nodes.

The following table lists the settings used in this example: Health tracking example settings.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

* Packet Interfaces = 1/2, 1/3, 1/5
Reduced Priority = 20

** Packet Interfaces = 1/5, 1/7
Reduced Priority = 55

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The execution flow is as follows on NS1 when multiple interface on NS1 goes down:

1. If interface 1/3 goes down, the priority of address VIP1 is reduced by 20 (VIP1's reduced priority value), because interface 1/3 is associated with VIP1:
    - Effective priority of VIP1 = (Current priority - reduced priority) = (90-20) = 70
2. Similarly, if interface 1/5 goes down, the priority of address VIP1 is further reduced:
    - Effective priority of VIP1 = (Current priority - reduced priority) = (70-20) = 50
3. At this point, the effective priority of VIP1 on NS1 is less than the priority of VIP1 on NS3. NS3 preempts NS1 for VIP1. VIP1 on NS3 takes over and becomes active (master).
4. Also, because interface 1/5 is also associated with VIP4, the priority of VIP4 is reduced by the VIP4's reduced priority value (55).
    - Effective priority of VIP4 = (250 - 55) = 195
5. If interface 1/7 goes down, the priority of VIP4 is further reduced:
    - Effective priority of VIP4 = (Current priority - reduced priority) = (195-55) = 145
6. At this point, the effective priority of VIP4 on NS1 is less than the priority of VIP4 on NS2. NS2 preempts NS1 for VIP4. VIP4 on NS3 takes over and becomes active (master). This configuration ensures that none of the four VIP addresses are active on NS1 before it completely goes down.

Configuration Steps for IPv4 Active-Active Mode

To configure this feature on a node for a VIP address, you set the Reduced Priority (trackifNumPriority) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP address by the configured Reduced Priority (trackifNumPriority) value.

To set reduced priority and bind interfaces to the virtual router ID by using the CLI:

At the command prompt, type:

- **set vrID** <id> [-**trackifNumPriority** <positive_integer>]
- **bind vrID** <id> -**trackifNum** <interface_name>
- **show vrID** <id>

Example:

```
> set vrID 125 -trackifNumPriority 10
Done

> bind vrID 125 -trackifNum 1/4 1/5
Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To set reduced priority and bind interfaces to the virtual router ID by using the GUI:

1. Navigate to **System** > **Network** > **VMAC.**
2. On the **VMACs** tab, select a virtual router ID, and click **Edit**.
3. Under **Configure virtual MAC**, set the **Reduced Priority** parameter.
4. Select the **Interfaces tracked for the VRID** option and, under **Associate Interfaces**, add interfaces to the virtual router ID.

Configuration Steps for IPv6 Active-Active Mode

To configure this feature on a node for a VIP6 address, you set the Reduced Priority (trackifNumPriority) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP6 address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP6 address by the configured Reduced Priority (trackifNumPriority) value.

To change the priority of a VIP address automatically by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new virtual MAC6:
  - **add vrID6** <id> [-**trackifNumPriority** <positive_integer>]
  - **bind vrID6** <id> -**trackifNum** <interface_name>
  - **show vrID6** <id>
- If reconfiguring an existing virtual MAC6:
  - **set vrID6** <id> [-**trackifNumPriority** <positive_integer>]
  - **bind vrID6** <id> -**trackifNum** <interface_name>
  - **show vrID6** <id>

Example:

```
> set vrID6 130 -trackifNumPriority 10
Done

> bind vrID6 130 -trackifNum 1/4 1/5
Done
```

Delaying Preemption

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

By default, a backup VIP address preempts the master VIP address immediately after its priority becomes higher than that of the master VIP. When configuring a backup VIP address, you can specify an amount of time by which to delay the preemption. Preemption delay time is a per-node setting for each backup VIP address.

The preemption delay setting for a backup VIP does not apply in the following conditions:

- The node of the master VIP goes down. In this case, the backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.
- The priority of the master VIP is set to zero. The backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.

Example: Delaying Preemption

Consider an active-active deployment consisting of Citrix ADC appliances NS1 and NS2. Virtual IP address VIP1 is configured on each of these appliances. Because of their priorities, VIP1 is master on NS2. Preemption is enabled and preemption delay time is set for VIP1 on these two nodes.

The following table lists the settings used in this example.

Entity and Parameters	Settings on NS1	Settings on NS2
VIP1 (for reference purposes only)	**IP address:** 192.0.1.10, **VRID:** 10, **Priority:** 100, **Preemption:** Enabled, **Preemption delay time:** 1000 seconds	**IP address:** 192.0.1.10, **VRID: 10**, **Priority:** 200, **Preemption:** Enabled, **Preemption delay time:** 2000 seconds
Dead Interval	1 Seconds	2 Seconds

Following are some examples of possible preemption behavior in this setup:

- If the priority of VIP1 on NS1 is set to a value (for example, 210) higher than that of VIP1 on NS2, VIP1 on NS1 takes over as master after its set preemption delay time (1000 secs).
- If a third node NS3 with the following VRRP settings is added to this deployment, VIP1 on NS3 becomes master after its set preemption delay time (3000 secs).
  - VIP1
    - VRID: 30
    - IP address:
    - Priority = 300
    - Preemption delay time = 3000 seconds

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- If NS2 goes down, VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.
- If NS2 goes down and NS1 restarts, VIP1 on NS1 becomes master 1 second (set dead interval on NS1) after NS1 comes up. Preemption delay time for VIP1 on NS1 does not apply in this case.
- If the priority of VIP1 on NS2 is set to zero, VIP1 goes to standby mode. VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.

Configuring Delay Preemption for IPv4 Active-Active Mode

To configure preemption delay time for a VIP address, you set the preemption delay timer parameter of the associated virtual MAC address. You can the set this parameter when you add the address, or you can modify an existing virtual MAC address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a virtual MAC, at the command prompt, type:
  - **add vrID** <id> -**preemptiondelaytimer** <secs>
  - **show vrID**
- To set the preemption delay time while modifying a virtual MAC, at the command prompt, type:
  - **set vrID** <id> -**preemptiondelaytimer** <secs>
  - **show vrID**

To configure preemption delay time by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**.
2. On the **VMAC** tab. While adding a new virtual MAC, or editing an existing virtual MAC, set the **Preemption Delay Timer** parameter.

Sample configuration:

The following configuration uses the settings listed in table in section Example: Delaying Preemption.

```
1     Settings on NS1
2
3     > set vrid param  – deadInterval 1
4
5     Done
6
7     > add ns ip 192.0.1.10 255.255.255.255  – type VIP
8
9     Done
10
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
11      > add vrid 10 -Priority 100 -Preemption Enable -
           preemptiondelaytimer 1000
12
13      Done
14
15      > bind ns ip 192.0.1.10 255.255.255.255 -vrid 10
16
17      Done
18
19      Settings on NS2
20
21      > set vrid param -deadInterval 2
22
23      Done
24
25      > add ns ip 192.0.1.10 255.255.255.255 -type VIP
26
27      Done
28
29      > add vrid 20 -Priority 200 -Preemption Enable -
           preemptiondelaytimer 2000
30
31      Done
32
33      > set ns ip 192.0.1.10 255.255.255.255 -vrid 10
34
35      Done
```

Configuring Delay Preemption for IPv6 Active-Active Mode

To configure preemption delay time for a VIP6 address, you set the preemption delay timer parameter of the associated virtual MAC6 address. You can the set this parameter when you add the virtual MAC6 address, or you can modify an existing virtual MAC6 address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a virtual MAC6, at the command prompt, type:
  - **add vrID6** <id> -**preemptiondelaytimer** <secs>
  - **show vrID6**
- To set the preemption delay time while modifying a virtual MAC6, at the command prompt, type:
  - **set vrID6** <id> -**preemptiondelaytimer** <secs>
  - **show vrID6**

To configure preemption delay time by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. On the **VMAC6** tab. While adding a virtual MAC6 address, or editing an existing virtual MAC6 address, set the **Preemption Delay Timer** parameter.

Keeping a VIP Address in the Backup State

September 14, 2021

You can force a VIP address to always stay in backup state. This operation is helpful in maintenance or testing of a VRRP deployment.

When a VIP address is forced to stay in backup state, it does not participate in VRRP state transitions. Also, it cannot become master even if all other nodes go down.

To force a VIP address to stay in backup state, you set the priority of the associated virtual MAC address to zero. To ensure that none of the VIP addresses of a node handle traffic during a maintenance process on the node, set all the priorities to zero.

You can the set the priority of a virtual MAC address while adding or modifying the address.

To force a VIP address to stay in the backup state by using the CLI:

- To set the priority while adding a virtual MAC, at the command prompt, type:
  - **add vrID** <id> -**priority** 0
  - **show vrID**
- To set the priority while modifying a virtual MAC, at the command prompt, type:
  - **set vrID** <id> -**priority** 0
  - **show vrID**

To force a VIP address to stay in backup state by using the GUI:

1. Navigate to **System** > **Network** > **VMAC**.
2. On the **VMAC** tab, while adding a new virtual MAC or editing an existing virtual MAC, set the **Priority** parameter to zero.

Network Visualizer

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The network visualizer shows a graphical view of all the interfaces, channels, VLANs, IP addresses, and bindings to VLANs on a Citrix ADC appliance. An enabled interface or channel has a black label. A disabled interface or channel has a red label.

This complete picture of the appliance's network connections can be useful for detecting flaws in the network design and for optimizing the network. It can also help a new administrator easily understand the appliance's network configuration.

To open the Network Visualizer:

Navigate to **System** > **Network**. In **Monitor Connections**, click **Network Visualizer**.

Configuring Link Layer Discovery Protocol

September 14, 2021

The Citrix ADC supports the industry standard (IEEE 802.1AB) Link Layer Discovery Protocol (LLDP). LLDP is a layer 2 protocol that enables the Citrix ADC to advertise its identity and capabilities to the directly connected devices, and also learn the identity and capabilities of these neighbour devices.

> **Note:**
> Link Layer Discovery Protocol (LLDP) is supported only in Citrix ADC MPX platforms.

Using LLDP, the Citrix ADC transmits and receives information in the form of LLDP messages known as LLDP packet data units (LLDPUs). An LLDPU is a sequence of type, length, value (TLV) information elements. Each TLV holds a specific type of information about the device that transmits the LLDPDU. The Citrix ADC sends the following TLVs in each LLDPU:

- Chassis ID
- Port ID
- Time-to-live value
- System name
- System description
- Port description
- System capabilities
- Management address
- Port VLAN ID
- Link aggregation

Note: You cannot specify the TLVs to be sent in LLDP messages.

Citrix ADC interfaces support the following LLDP modes:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **NONE**. The interface neither receives from nor transmits LLDP messages to the directly connected device.
- **TRANSMITTER**. The interface transmits LLDP messages to the directly connected device but does not receive LLDP messages from the directly connected device.
- **RECEIVER**. The interface receives LLDP messages from the directly connected device but does not transmit LLDP messages to the directly connected device.
- **TRANSCEIVER**. The interface transmits LLDP messages to and receives LLDP messages from the directly connected device.

The LLDP mode of an interface depends on the LLDP mode configured at the global and the interface levels. The following table shows the modes resulting from the available combinations of global- and interface-level settings: Interface and global level LLDP modes.

Note the following points related to LLDP messages transmitted or received by the Citrix ADC:

- **Transmitting LLDP messages.** The Citrix ADC transmits LLDPUs from interfaces that are operating in either TRANSMITTER or TRANSCEIVER LLDP mode.

  Following are the global LLDP transmitting parameters on the Citrix ADC:

  - **Timer**. Interval, in seconds, between LLDPUs that the Citrix ADC sends to a directly connected device.
  - **Holdtime Multiplier**. A multiplier for calculating the duration for which the receiving device stores the LLDP information in its database before discarding or removing it. The duration is calculated as the **Holdtime Multiplier** parameter value multiplied by the Timer parameter value.

- **Receiving LLDP Messages.** The Citrix ADC stores the LLDPDU information in its Management Information base (MIB). The stored LLDP information is classified or grouped under the ID of the interface that received the LLDPDU. The Citrix ADC retains this LLDP information for the duration specified in the received LLDPU.

  If the ADC receives another LLDPDU on an interface before the stored LLDP information for that interface is discarded, the ADC replaces the stored LLDP information for that interface with information in the new LLDPDU.

Configuration Steps

Configuring LLDP on a Citrix ADC appliance consists of the following tasks:

1. **Set global level LLDP parameters.** In this task, you set the global LLDP parameters such as LLDP Timer, Hold Time Multiplier, and LLDP mode.
2. **Set the interface level LLDP parameters.** In this task, you set the LLDP mode for an interface.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. **(Optional) Display neighbor-device information.** You can display the neighbor-device LLDP information collected on all of the Citrix ADC's interfaces, or just the LLDP information collected on specified interfaces. If you do not specify an interface, the information is shown for all interfaces.

Following are the prerequisites for configuring LLDP on a Citrix ADC:

1. Make sure that you understand the standard LLDP protocol (IEEE 802.1AB).
2. Verify that you have configured LLDP on the desired directly connected devices.

CLI procedures

To set global level LLDP parameters by using the CLI:

At the command prompt, type:

- set lldp param [-[-holdtimeTxMult <positive_integer>][-timer <positive_integer>] [-Mode <Mode>]
- show lldp param

To configure an interface for LLDP by using the CLI:

At the command prompt, type:

- set interface <id> -lldpmode <lldpmode>
- show interface <id>

To display neighbor device information by using the CLI:

At the command prompt, type one of the following commands:

- show lldp neighbors
- show lldp neighbors <ifnum>

GUI procedures

To set the global level LLDP parameters by using the GUI:

1. Navigate to System > Network, and click Configure LLDP Parameters.
2. Set the following parameters:
    - Hold Timer Multiplier
    - Timer
    - Mode

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure an interface for LLDP by using the GUI:

Navigate to System > Network > Interfaces, open the interface, and set the LLDP mode parameter.

To display neighbor device information by using the GUI:

Navigate to System > Network > Interfaces and, in the Action list, select View LLDP Neighbors.

LLDP Support in a Cluster Setup

In a cluster setup, the GUI and CLI display the LLDP neighbour configuration of all or specific cluster nodes when the GUI or CLI is accessed through the Cluster IP address (CLIP). Any change made to the global level LLDP mode is applied to the global level LLDP mode on each of the cluster nodes.

Consider an example of a cluster setup of three nodes, NS1, NS2, and NS3. Each of these nodes are connected to both routers Router-1 and Router-2. The following output is displayed when the **show lldp neighbor -summary** operation is performed on the Cluster CLI that is accessed through the Cluster IP address (CLIP) of the cluster setup. The output shows the LLDP neighbour information of all these nodes.

```
> show lldp neighbor -summary

Node Id: 1
------------------------------------------------------------
    Interface    ChassisId           PortId     System name
------------------------------------------------------------
1     1/1/1      fe:c7:3b:13:bd:11    1/1         Router-1

2     1/1/2      12:68:7b:9e:4c:11    1/1         Router-2

Node Id: 2
------------------------------------------------------------
    Interface    ChassisId           PortId     System name
------------------------------------------------------------
1     2/1/1      fe:c7:3b:13:bd:12    1/2        Router-1

2     2/1/2      12:68:7b:9e:4c:12    1/2        Router-2

Node Id: 3
------------------------------------------------------------
    Interface    ChassisId           PortId     System name
------------------------------------------------------------

1     3/1/1       fe:c7:3b:13:bd:13    1/3        Router-1

2     3/1/2       12:68:7b:9e:4c:13    1/3        Router-2

Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Jumbo Frames

September 14, 2021

Citrix ADC appliances support receiving and transmitting jumbo frames containing up to 9216 bytes of IP data. Jumbo frames can transfer large files more efficiently than it is possible with the standard IP MTU size of 1500 bytes.

A Citrix ADC appliance can use jumbo frames in the following deployment scenarios:

- Jumbo to Jumbo. The appliance receives data as jumbo frames and sends it as jumbo frames.
- Non-Jumbo to Jumbo. The appliance receives data as regular frames and sends it as jumbo frames.
- Jumbo to Non-Jumbo. The appliance receives data as jumbo frames and sends it as regular frames.

The Citrix ADC appliance supports jumbo frames in a load balancing configuration for the following protocols:

- TCP
- Any protocol over TCP (for example, HTTP)
- SIP
- RADIUS

Configuring Jumbo Frames Support on a Citrix ADC Appliance

September 14, 2021

To enable the Citrix ADC appliance to support jumbo frames, you set the MTU to more than 1500 on interfaces or LA channels, and on VLANs on which you want the Citrix ADC appliance to support jumbo frames.

Points to consider before setting the MTU of interfaces, LA channels, or VLANs on a Citrix ADC appliance

1. When you create an LA channel, the channel takes the MTU of the first bound interface if no MTU is specified for the channel.
2. The MTU for a channel is propagated to all the bound interfaces.
3. When an interface is bound to the channel whose MTU is different from the interface's MTU, the interface goes onto the inactive list.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. When you change the MTU of a member interface, the interface goes onto the inactive list.
5. When an interface is unbound from the channel, the interface retains the MTU value of the channel.
6. You can set the MTU for an interface, channel, or VLAN to a value in the range of 1500-9216.
7. You cannot set the MTU on the default VLAN. The Citrix ADC appliance uses the MTU of the interface through which it receives or sends data from or to the default VLAN.
8. For TCP based traffic on a load balancing configuration on a Citrix ADC appliance, MSSs are set accordingly at each end point for supporting jumbo frames:

    - For a connection between a client and a load balancing virtual server on the Citrix ADC appliance, the MSS on the Citrix ADC appliance is set in a TCP profile, which is then bound to the load balancing virtual server.
    - For a connection between the Citrix ADC appliance and a server, the MSS on NS1 is set in a TCP profile, which is then bound to the service representing the server on the Citrix ADC appliance.
    - By default, a TCP profile nstcp_default_profile is bound to all TCP based load balancing servers and services on the Citrix ADC appliance.
    - For supporting jumbo frames, you can either change the MSS value of the TCP profile nstcp_default_profile, or create a custom TCP profile and set its MSS accordingly, and then bind the custom TCP profile to the desired load balancing virtual servers and services.
    - The default MSS value of any TCP profile is 1460.

CLI procedures

To set the MTU of an interface by using the CLI:

At the command prompt, type:

- set interface <id> -mtu <positive_integer>
- show interface <id>

Example:

```
1 > set interface 10/1  – mtu 9000
2 Done
```

To set the MTU of a channel by using the CLI:

At the command prompt, type:

- set channel <id> -mtu <positive_integer>
- show channel <id>

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
> set channel LA/1 –mtu 9000
Done
```

To set the MTU of a VLAN by using the CLI:

At the command prompt, type:

- add vlan <id> -mtu <positive_integer>
- show vlan <id>

Example:

```
> set vlan 20 –mtu 9000
Done
```

GUI procedures

To set the MTU of an interface by using the GUI:

Navigate to System > Network > Interfaces, open the interface, and set the Maximum Transmission Unit parameter.

To set the MTU of a channel by using the GUI:

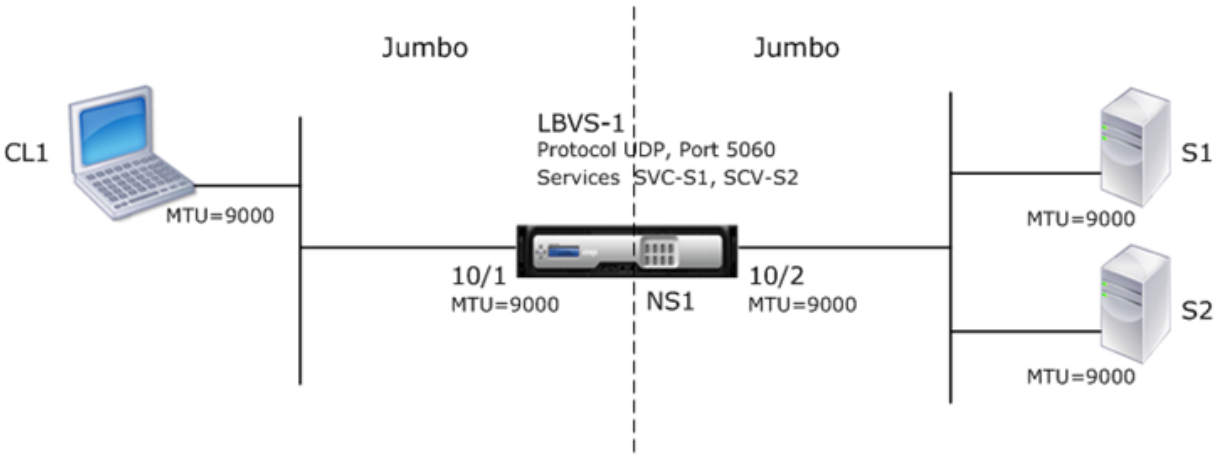
Navigate to System > Network > Channels, open the channel, and set the Maximum Transmission Unit parameter.

To set the MTU of a VLAN by using the GUI:

Navigate to System > Network > VLANs, open the VLAN, and set the Maximum Transmission Unit parameter.

Use Case 1 –Jumbo to Jumbo Setup

September 14, 2021



Consider an example of a jumbo to jumbo setup in which SIP load balancing virtual server LBVS-1, configured on Citrix ADC appliance NS1, is used to load balance SIP traffic across servers S1 and S2. The connection between client CL1 and NS1, and the connection between NS1 and the servers support jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2. Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For supporting jumbo frames, the MTU is set to 9216, on NS1, for interfaces 10/1, 10/2, and VLANs VLAN 10, VLAN 20.

All other network devices, including CL1, S1, S2, in this setup example are also configured for supporting jumbo frames.

The following table lists the settings used in the example.

Entity	Name	Details
IP address of client CL1	-	192.0.2.10
IP address of servers	S1	198.51.100.19
		S2
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	9000
		10/2
		VLAN 10
		VLAN 20
Services on NS1 representing servers	SVC-S1	**IP address:** 198.51.100.19, **Protocol:** SIP, **Port:** 5060
		SVC-S2
Load balancing virtual server on VLAN 10	LBVS-1	**IP address:** 203.0.113.15, **Protocol:** SIP, **Port:** 5060, **Bound services:** SVC-S1, SVC-S2

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Following is the traffic flow of CL1's request to NS1:

1. CL1 creates a 20000-byte SIP request to send to LBVS-1 of NS1.
2. CL1 sends the request data in IP fragments to LBVS-1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which CL1 sends these fragments to NS1.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
    - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
    - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 2048] = 2068
3. NS1 receives the request IP fragments at interface 10/1. NS1 accepts these fragments, because the size of each of these fragments is equal to or less than the MTU (9000) of interface 10/1.
4. NS1 reassembles these IP fragments to form the 20000-byte SIP request. NS1 processes this request.
5. LBVS-1's load balancing algorithm selects server S1.
6. NS1 sends the request data in IP fragments to S1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/2, from which NS1 sends these fragments to S1. The IP packets are sourced with a SNIP address of NS1.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
    - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
    - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 2048] = 2068

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates a 30000-byte SIP response to send to the SNIP address of NS1.
2. S1 sends the response data in IP fragments to the SNIP address of NS1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which S1 sends these fragments to NS1.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
    - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
    - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088
3. NS1 receives the response IP fragments at interface 10/2. NS1 accepts these fragments, because the size of each fragment is equal to or less than the MTU (9000) of interface 10/2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. NS1 reassembles these IP fragments to form the 30000-byte SIP response. NS1 processes this response.
5. NS1 sends the response data in IP fragments to CL1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/1, from which NS1 sends these fragments to CL1. The IP fragments are sourced with LBVS-1's IP address.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
    - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
    - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088

Configuration Tasks

The following table list the tasks, Citrix ADC commands, and examples for creating the required configuration on the Citrix ADC appliance.

Task	Citrix ADC Command Syntax	Example
Set the MTU of the desired interfaces for supporting jumbo frames	set interface -mtu , show interface	set int 10/1 -mtu 9000 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan -mtu , show vlan	add vlan 10 -mtu 9000 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan -ifnum , show vlan	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip -type SNIP, show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP
Create services representing SIP servers	add service SIP_UDP , show service	add service SVC-S1 198.51.100.19 SIP_UDP 5060 add service SVC-S2 198.51.100.20 SIP_UDP 5060
Create SIP load balancing virtual servers and bind the services to it	add lb vserver SIP_UDP bind lb vserver , show lb vserver	add lb vserver LBVS-1 SIP_UDP 203.0.113.15 5060 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2
Save the configuration	save ns config, show ns config	

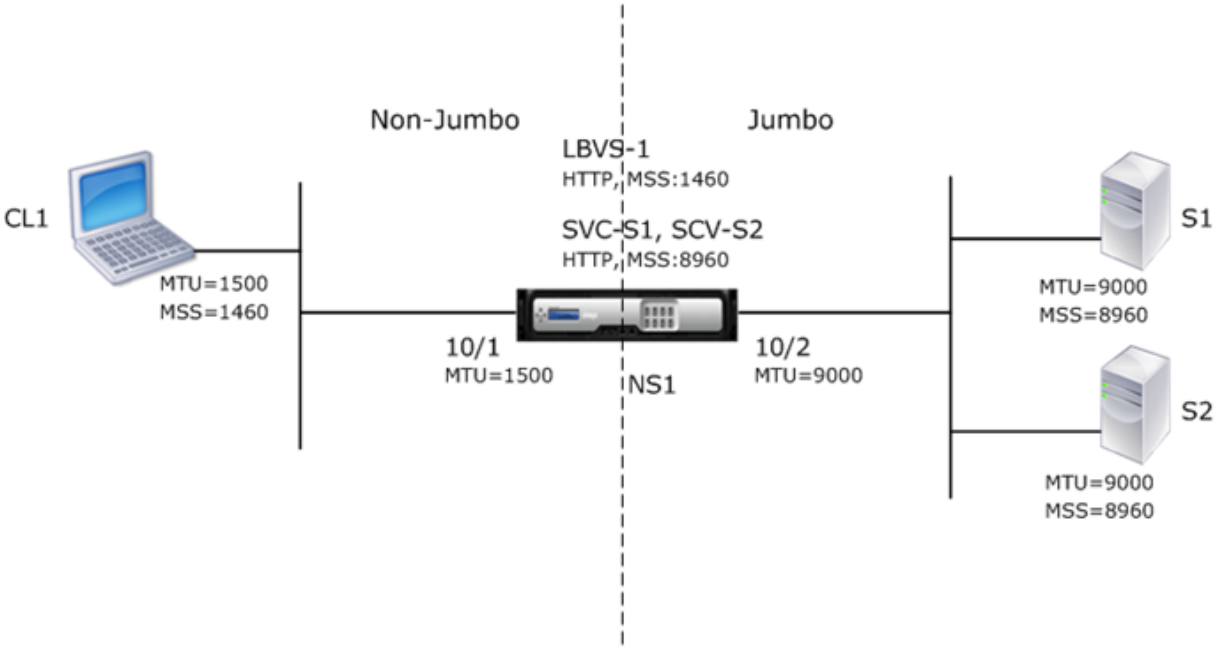
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Use Case 2 –Non-Jumbo to Jumbo Setup

September 14, 2021

Consider an example of a regular to jumbo setup in which load balancing virtual server LBVS-1, configured on a Citrix ADC appliance NS1, is used to load balance traffic across servers S1 and S2. The connection between client CL1 and NS1 supports regular frames, and the connection between NS1 and the servers supports jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2.



Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively. For supporting only regular frames between CL1 and NS1, the MTU is set to the default value of 1500 for both interface 10/1 and VLAN 10

For supporting jumbo frames between NS1 and the servers, the MTU is set to 9000 for interface 10/2 and VLAN 20. Servers and all other network devices between NS1 and the servers are also configured for supporting jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For supporting jumbo frames for the connection between a SNIP address of NS1 and S1 or S2, the MSS on NS1 is set accordingly in a custom TCP profile, which is bound to the services (SVC-S1 and SVC-S1) representing S1 and S2 on NS1.
- For supporting only regular frames for the connection between CL1 and virtual server LBVS-1 of NS1, default TCP profile nstcp_default_profile is used that is by default bound to LBVS-1 and has the MSS set to the default value of 1460.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following table lists the settings used in this example.

Entity	Name	Details
IP address of client CL1		192.0.2.10
IP address of servers	S1	198.51.100.19
		S2
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	1500
		10/2
		VLAN 10
		VLAN 20
Default TCP profile	nstcp_default_profile	MSS:1460
Custom TCP profile	NS1-SERVERS-JUMBO	MSS: 8960
Services on NS1 representing servers	SVC-S1	IP address: 198.51.100.19, Protocol: HTTP, Port: 80, TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)
		SVC-S2

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity	Name	Details
Load balancing virtual server on VLAN 10	LBVS-1	IP address = 203.0.113.15, Protocol: HTTP, Port:80, Bound services: SVC-S1, SVC-S2, TCP Profile: nstcp_default_profile (MSS:1460)

Following is the traffic flow of CL1's request to S1 in this example:

1. Client CL1 creates a 200-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their respective TCP MSS values while establishing the connection.
3. Because NS1's MSS is larger than the HTTP request, CL1 sends the request data in a single IP packet to NS1.

   Size of the request packet = [IP Header + TCP Header + TCP Request] = [20 + 20 + 200] = 240
4. NS1 receives the request packet at interface 10/1 and then processes the HTTP request data in the packet.
5. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
6. Because S1's MSS is larger than the HTTP request, NS1 sends the request data in a single IP packet to S1.

   Size of the request packet = [IP Header + TCP Header + [TCP Request] = [20 + 20 + 200] = 240

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates an 18000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.

   - Size of the first two packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
3. NS1 receives the response packets at interface 10/2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. From these IP packets, NS1 assembles all the TCP segments to form the HTTP response data of 18000 bytes. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets, from interface 10/1, to CL1. These IP packets are sourced from LBVS-1's IP address and destined to CL1's IP address.
    - Size of all packets except the last one = [IP Header + TCP Header + (TCP payload=CL1's MSS size)] = [20 + 20 + 1460] = 1500
    - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 480] = 520

Configuration Tasks

The following table list the tasks, Citrix ADC commands, and examples for creating the required configuration on the Citrix ADC appliance.

Tasks	CLI Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface -mtu , show interface	set int 10/1 -mtu 1500 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan -mtu , show vlan	add vlan 10 -mtu 1500 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan -ifnum , show vlan	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip -type SNIP, show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP
Create services representing HTTP servers	add service HTTP , show service	add service SVC-S1 198.51.100.19 http 80, add service SVC-S2 198.51.100.20 http 80
Create HTTP load balancing virtual servers and bind the services to it	add lb vserver HTTP , bind lb vserver , show lb vserver	add lb vserver LBVS-1 http 203.0.113.15 80, bind lb vserver LBVS-1 SVC-S1, bind lb vserver LBVS-1 SVC-S2
Create a custom TCP profile and set its MSS for supporting jumbo frames	add tcpProfile -mss , show tcpProfile	add tcpprofile NS1-SERVERS-JUMBO -mss 8960

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Tasks	CLI Syntax	Examples
Bind the custom TCP profile to the desired services	set service -tcpProfileName , show service	set service SVC-S1 -tcpProfileName NS1-SERVERS-JUMBO, set service SVC-S2 -tcpProfileName NS1-SERVERS-JUMBO
Save the configuration	save ns config, show ns config	

Use Case 3 –Coexistence of Jumbo and Non-Jumbo flows on the Same Set of Interfaces

September 14, 2021

Consider an example in which load balancing virtual servers LBVS-1 and LBVS-2 are configured on Citrix ADC appliance NS1. LBVS-1 is used to load balance HTTP traffic across servers S1 and S2, and LBVS-2 is used to load balance traffic across servers S3 and S4.

CL1 is on VLAN 10, S1 and S2 are on VLAN20, CL2 is on VLAN 30, and S3 and S4 are on VLAN 40. VLAN 10 and VLAN 20 support jumbo frames, and VLAN 30 and VLAN 40 support only regular frames.

In other words, the connection between CL1 and NS1, and the connection between NS1 and server S1 or S2 support jumbo frames. The connection between CL2 and NS1, and the connection between NS1 and server S3 or S4 support only regular frames.

Interface 10/1 of NS1 receives or sends traffic from or to clients. Interface 10/2 of NS1 receives or sends traffic from or to the servers.

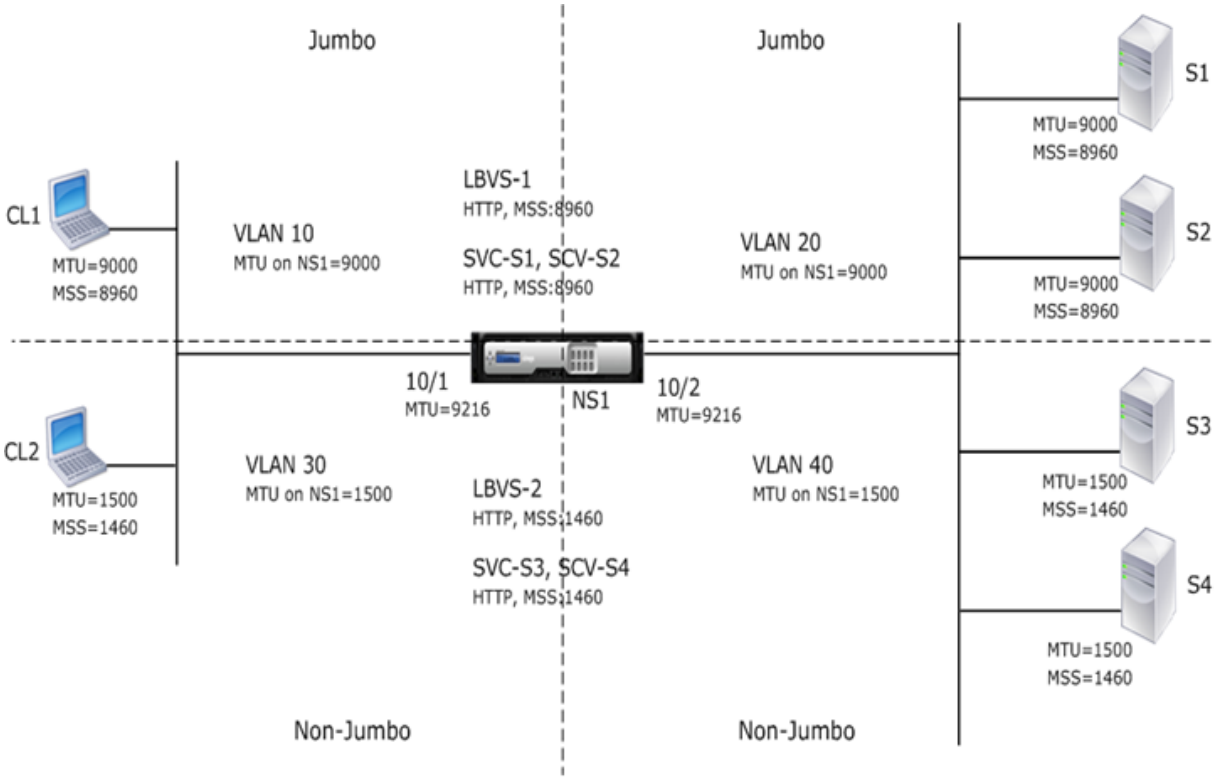
Interface 10/1 is bound to both VLAN 10 and VLAN 30 as a tagged interface, and interface 10/2 is bound to both VLAN 20 and VLAN 40 as a tagged interface.

For supporting jumbo frames, the MTU is set to 9216 for interfaces 10/1 and 10/2.

On NS1, the MTU is set to 9000 for VLAN 10 and VLAN 20 for supporting jumbo frames, and the MTU is set to the default value of 1500 for VLAN 30 and VLAN 40 for supporting only regular frames.

The effective MTU on a Citrix ADC interface for VLAN tagged packets is of the MTU of the interface or the MTU of the VLAN, whichever is lower. For example:

- The MTU of interface 10/1 is 9216. The MTU of VLAN 10 is 9000. On interface 10/1, the MTU of VLAN 10 tagged packets is 9000.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- The MTU of interface 10/2 is 9216. The MTU of VLAN 20 is 9000. On interface 10/2, the MTU of VLAN 20 tagged packets is 9000.
- The MTU of interface 10/1 is 9216. The MTU of VLAN 30 is 1500. On interface 10/1, the MTU of VLAN 30 tagged packets is 1500.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 40 is 1500. On interface 10/2, the MTU of VLAN 40 tagged packets is 9000.

CL1, S1, S2, and all network devices between CL1 and S1 or S2 are configured for jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For the connection between CL1 and virtual server LBVS-1 of NS1, the MSS on NS1 is set in a TCP profile, which is then bound to LBVS-1.
- For the connection between a SNIP address of NS1 and S1, the MSS on NS1 is set in a TCP profile, which is then bound to the service (SVC-S1) representing S1 on NS1.

The following table lists the settings used in this example: Jumbo frames use case 3 example settings.

Following is the traffic flow of CL1's request to S1:

1. Client CL1 creates a 20000-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their TCP MSS values while establishing the connection.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. Because NS1's MSS value is smaller than the HTTP request, CL1 segments the request data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 10 to NS1.
    - Size of the first two packets = [IP Header + TCP Header + (TCP segment=NS1 MSS)] = [20 + 20 + 8960] = 9000
    - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
4. NS1 receives these packets at interface 10/1. NS1 accepts these packets because the size of these packets is equal to or less than the effective MTU (9000) of interface 10/1 for VLAN 10 tagged packets.
5. From the IP packets, NS1 assembles all the TCP segments to form the 20000-byte HTTP request. NS1 processes this request.
6. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
7. NS1 segments the request data into multiples of S1's MSS and sends these segments in IP packets tagged as VLAN 20 to S1.
    - Size of the first two packets = [IP Header + TCP Header + (TCP payload=S1 MSS)] = [20 + 20 + 8960] = 9000
    - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

Following is the traffic flow of S1's response to CL1:

1. Server S1 creates a 30000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 20 to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
    - Size of first three packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
    - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160
3. NS1 receives the response packets at interface 10/2. NS1 accepts these packets, because their size is equal to or less than the effective MTU value (9000) of interface 10/2 for VLAN 20 tagged packets.
4. From these IP packets, NS1 assembles all the TCP segments to form the 30000-byte HTTP response. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets tagged as VLAN 10, from interface 10/1, to CL1. These IP packets are sourced from LBVS's IP address and destined to CL1's IP address.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Size of first three packet = [IP Header + TCP Header + [(TCP payload=CL1's MSS size)] = [20 + 20 + 8960] = 9000
- Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160

Configuration Tasks

Following table lists tasks, commands, and examples for creating the required configuration on the Citrix ADC appliance: Jumbo frames use case 3 configuration tasks.

Citrix ADC Support for Microsoft Direct Access Deployment

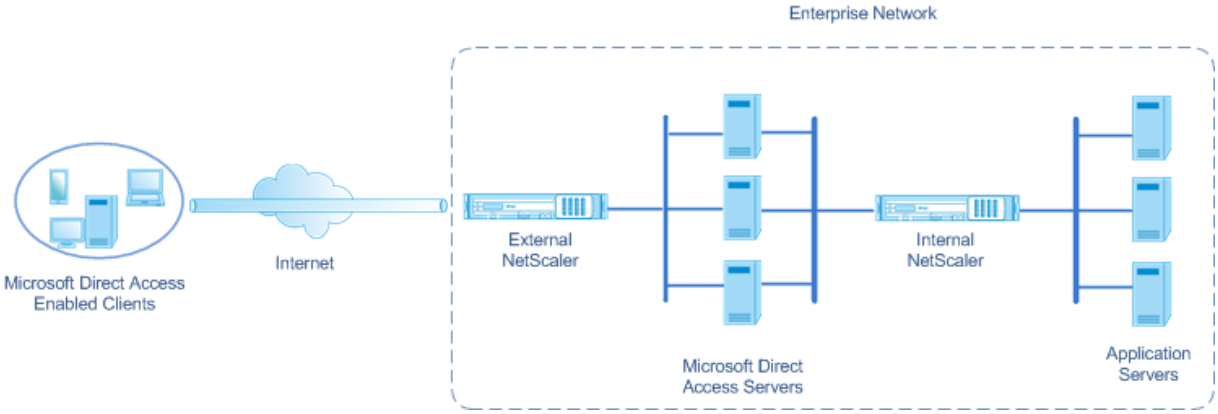
September 14, 2021

Microsoft Direct Access is a technology that enables remote users to seamlessly and securely connect to the enterprise's internal networks, without the need to establish a separate VPN connection. Unlike VPN connections, which require user intervention to open and close connections, a Direct Access-enabled client connects automatically to the enterprise's internal networks whenever the client connects to the Internet.

Manage-Out is a Microsoft Direct Access feature that allows administrators inside the enterprise network to connect to Direct Access clients outside the network and manage them (for example, performing administration tasks, such as scheduling service updates, and providing remote support.

In a Direct Access deployment, Citrix ADC appliances provide high availability, scalability, high performance, and security. Citrix ADC load balancing functionality sends client traffic through the most appropriate server. The appliances can also forward Manage-Out traffic through the right path to reach the client.

Architecture



The architecture of a Microsoft Direct Access deployment consists of Direct Access enabled clients, Direct Access servers, application servers, and internal and external Citrix ADC appliances. Clients connect to an application server through a Direct Access server. An external Citrix ADC appliance load balance the client traffic to a Direct Access server, and an Internal Citrix ADC appliance forwards the client traffic from the Direct Access server to the destination application server. Direct Access is used for tunneling the client's IPv6 traffic over the IPv4 network. An IPv4 load balancing virtual server on the external Citrix ADC appliance load balances the client's tunneled traffic to one of the Direct Access servers. The Direct Access server extracts the IPv6 packets from the received client's IPv4 packets

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

and sends them to the destination application server through the internal Citrix ADC appliance. The Internal Citrix ADC appliance has forwarding session rules with the source route cache option enabled for storing Layer 2 and Layer 3 connection information about the client's traffic from the Direct Access Server. The Citrix ADC appliance stores the following Layer 2 and Layer 3 information in a table called the source route cache table:

- Source IP address of the received packet
- MAC address of the Direct Access server that sent the packet
- VLAN ID of the Citrix ADC appliance that received the packet
- Interface ID of the Citrix ADC appliance that received the packet

The Citrix ADC appliance uses the information in the source route cache table for forwarding a response to the same Direct Access server because it has the tunneling information to reach the client. Also, the Internal appliance uses the source route cache table to forward application server's Manage-out traffic to the appropriate Direct Access server to reach a particular client.

Configuring the Internal Citrix ADC Appliance in a Microsoft Direct Access Deployment

To configure the Internal Citrix ADC appliance for forwarding an application server's response and manage-out traffic to the appropriate Direct Access Gateway, configure forwarding session rules. In each rule, set the sourceroutecache parameter to ENABLED.

To create a forwarding session rule by using the CLI:

At the command prompt, type:

- **add forwardingSession** <name> ((<network> [<netmask>]) | **-acl6name** <string> | **-aclname** <string>) **-sourceroutecache** (**ENABLED** | **DISABLED**]
- **show forwardingsession** <name>

Sample configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

In the following example, forwarding-session rule MS-DA-FW-1 is created on the internal Citrix ADC appliance. The forwarding session stores Layer 2 and Layer 3 information for any incoming IPv6 packets from a Direct Access server that matches source IPv6 prefix 2001:DB8::/96.

```
> add forwardingSession MS-DA-FW-1 2001:DB8::/96 -sourceroutecache -
    ENABLED
 Done
```

Displaying the Source Route Cache Table

You can display the source route cache table for monitoring or detecting any unwanted connections between direct access servers and application servers.

To display the source route cache table by using the CLI:

At the command prompt, type:

- **show sourceroutecachetable**

Example:

```
> show sourceroutecachetable
SOURCEIP            MAC                VLAN    INTERFACE
2001:DB8:5001:10    56:53:24:3d:02:eb    30        1/2
2001:DB8:5003:30    60:54:35:3e:04:bd    60        1/3
Done
```

Clearing the Source Route Cache Table

You can clear all the entries from the source route cache table on a Citrix ADC appliance.

To clear the source route cache table by using the CLI:

At the command prompt, type:

- **flush ns sourceroutecachetable**

Access Control Lists

September 14, 2021

Access Control Lists (ACLs) filter IP traffic and secure your network from unauthorized access. An ACL is a set of conditions that the Citrix ADC evaluates to determine whether to allow access. For example, the Finance department probably does not want to allow its resources to be accessed by other

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

departments, such as HR and Documentation, and those departments want to restrict access to their data.

When the Citrix ADC receives a data packet, it compares the information in the data packet with the conditions specified in the ACL and allows or denies access. The administrator of the organization can configure ACLs to function in the following processing modes:

- ALLOW—Process the packet.
- BRIDGE—Bridge the packet to the destination without processing it. The packet is directly sent by Layer 2 and Layer 3 forwarding.
- DENY—Drop the packet.

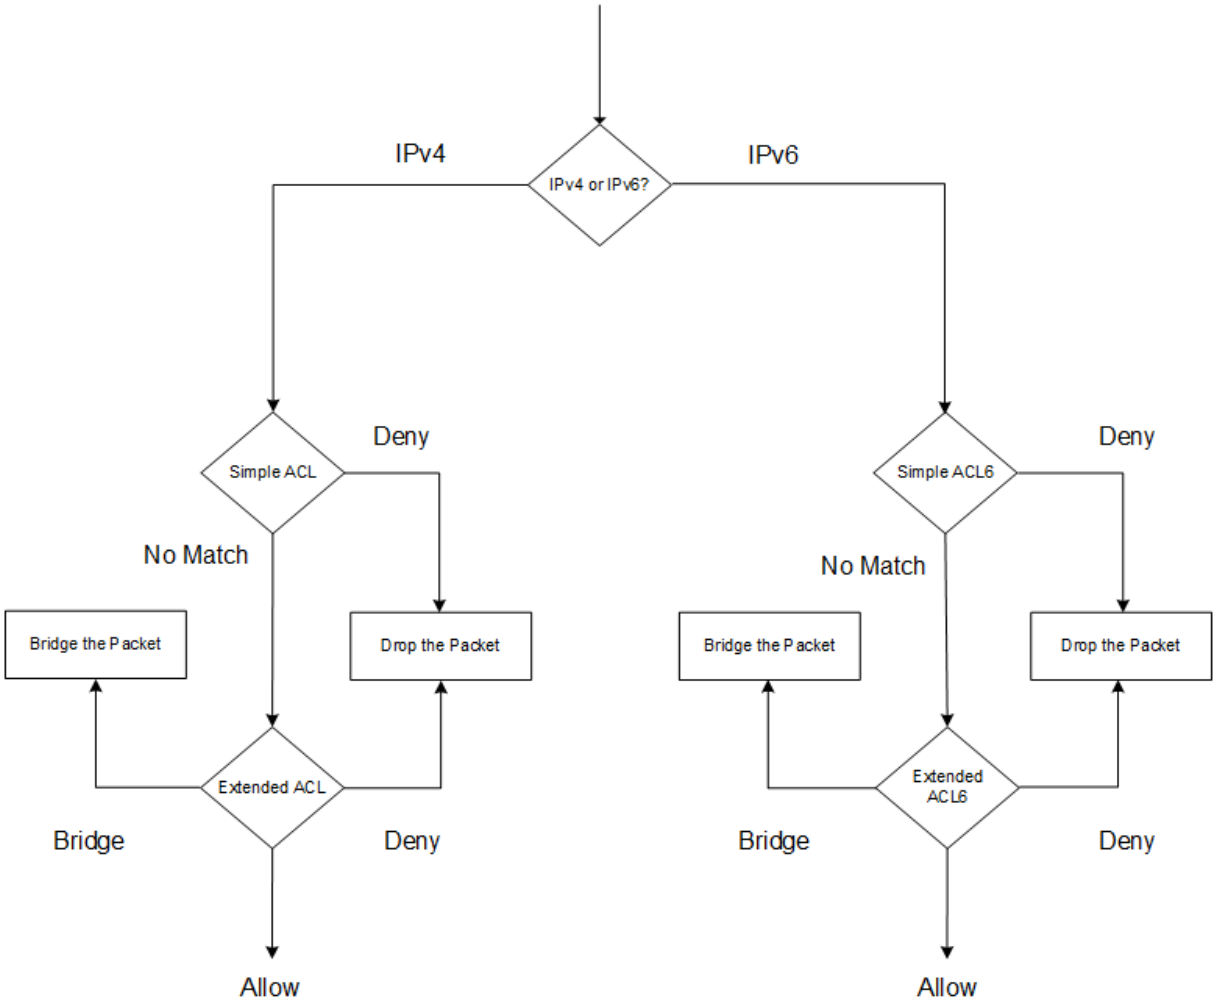
ACL rules are the first level of defense on the Citrix ADC.

Citrix ADC supports the following types of ACLs:

- **Simple ACLs** filter packets based on their source IP address and, optionally, their protocol, destination port, or traffic domain. Any packet that has the characteristics specified in the ACL is dropped.
- **Extended ACLs** filter data packets based on various parameters, such as source IP address, source port, action, and protocol. An extended ACL defines the conditions that a packet must satisfy for the Citrix ADC to process the packet, bridge the packet, or drop the packet.

Nomenclature

In the Citrix ADC user interfaces, the terms simple ACL and extended ACL refer to ACLs that process IPv4 packets. An ACL that processes IPv6 packets is called a simple ACL6 and or extended ACL6. When discussing both types, this documentation sometimes refers to both of them as simple ACLs or extended ACLs.



ACL Precedence

If both simple and extended ACLs are configured, incoming packets are compared to the simple ACLs first.

The Citrix ADC first determines whether the incoming packet is an IPv4 or an IPv6 packet, and then compares the packet's characteristics to either simple ACLs or simple ACL6s. If a match is found, the packet is dropped. If no match is found, the packet is compared to extended ACLs or extended ACL6s. If that comparison results in a match, the packet is handled as specified in the ACL. The packet can be bridged, dropped, or allowed. If no match is found, the packet is allowed.

Figure 1. Simple and Extended ACLs Flow Sequence

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Simple ACLs and Simple ACL6s

September 14, 2021

A simple ACL or simple ACL6 uses few parameters and can be configured only to drop IP packets. Packets can be dropped based on their source IP address and, optionally, their protocol, destination port, or traffic domain.

When creating a simple ACL or simple ACL6, you can specify a time to live (TTL), in seconds, after which the ACL expires. ACLs with TTLs are not saved when you save the configuration. You can display simple ACLs and simple ACL6s to verify their configuration, and you can display their statistics.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring Simple ACLs and Simple ACL6s

Configuring a simple ACL or simple ACL6 on a Citrix ADC can include the following tasks.

- **Create simple ACLs or simple ACL6s**. Creating simple ACLs or simple ACL6s to drop (deny) packets based on their source IP address and, optionally, their protocol, destination port, or traffic domain.
- **Remove simple ACLs or simple ACL6s**. These ACLs cannot be modified once created. If you must modify a simple ACL or simple ACL6, you must remove it and create a one.

CLI procedures

To create a simple ACL by using the CLI:

At the command prompt, type:

```
1 - ns simpleacl <aclname> DENY -srcIP <ip_addr> [-destPort <port> -
    protocol ( TCP | UDP )] [-TTL \<positive_integer>]
2 - show ns simpleacl [\<aclname>]
```

Example:

```
1 > add simpleacl rule1 DENY -srcIP 10.102.29.5 -TTL 600
2 Done
```

To create a simple ACL6 by using the CLI:

At the command prompt, type:

```
1 - add ns simpleacl6 <aclname> DENY - srcIPv6 <ipv6_addr|null> [-
    destPort <port> -protocol ( TCP | UDP )] [-TTL <positive_integer>]
2 - show ns simpleacl6 [<aclname>]
```

Example:

```
1 > add ns simpleacl6 rule1 DENY – srcIPv6 3ffe:192:168:215::82 -
    destPort 80 -Protocol TCP -TTL 9000
2  Done
```

To remove a single simple ACL by using the CLI:

At the command prompt, type:

- **rm ns simpleacl** <aclname>
- **show ns simpleacl**

To remove a single simple ACL6 by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **rm ns simpleacl6**<aclname>
- **show ns simpleacl6**

To remove all simple ACLs by using the CLI:

At the command prompt, type:

- **clear ns simpleacl**
- **show ns simpleacl**

To remove all simple ACL6s by using the CLI:

At the command prompt, type:

- **clear ns simpleacl6**
- **show ns simpleacl6**

GUI procedures

To create a simple ACL by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACLs** tab, add a new simple ACL.

To create a simple ACL6 by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, add a new simple ACL6.

To remove a single simple ACL by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACLs** tab, delete the simple ACL.

To remove a single simple ACL6 by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, delete the simple ACL6.

To remove all simple ACLs by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACLs** tab, in the **Action** list, click **Clear**.

To remove all simple ACL6s by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Clear**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Displaying Simple ACL and Simple ACL6 Statistics

You can display the simple ACL (or simple ACL6) statistics, which include the number of matches, the number of misses, and the number of simple ACLs configured.

The following table describes the statistics you can display for simple ACLs and simple ACL6s.

Statistics	Indicates
ACL match	Packets matching an ACL
ACL misses	Packets not matching any ACL
ACL count	Number of ACLs configured

CLI procedures

To display simple ACL statistics by using the CLI:

At the command prompt, type:

- **stat ns simpleacl**

Example:

```
> stat ns simpleacl

SimpleACL Statistics

                                          Rate (/s)
                                             Total
SimpleACL hits                                    0
                        0
SimpleACL misses                                  0
    51872
SimpleACLs count                                 --
                        2
Done
```

To display simple ACL6 statistics by using the CLI:

At the command prompt, type:

- **stat ns simpleacl6**

GUI procedures

To display simple ACL statistics by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Navigate to **System** > **Network** > **ACLs** and, on the **Simple ACLs** tab, select the ACL and click **Statistics**.

To display simple ACL6 statistics by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, select the simple ACL6 and click **Statistics**.

Terminating Established Connections

For a simple ACL or simple ACL6, the Citrix ADC blocks any new connections that match the conditions specified in the ACL. Packets related to existing connections that were established before the ACL was created are not blocked. To terminate previously established connections that match an existing ACL, you can run a flush operation from the CLI or the GUI.

Flush can be useful in the following cases:

- You receive a list of blacklisted IP addresses and want to completely block those IP addresses from accessing the Citrix ADC. In this case, you create simple ACLs or simple ACL6s to block any new connections from these IP addresses, and then flush any existing connections associated with those addresses.
- You want to terminate many connections from a particular network without taking the time to terminate them one by one.

Before you begin

- When you run flush, the Citrix ADC searches through all of its established connections and terminates the connections that match the conditions specified in any of the simple ACLs configured on the ADC.
- If you plan to create more than one simple ACL and flush existing connections that match any of them, you can minimize the effect on performance by first creating all simple ACLs and then running flush only once.

CLI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the CLI:

At the command prompt, type:

- **flush simpleacl -estSessions**

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the CLI:

At the command prompt, type:

- **flush simpleacl6 -estSessions**

GUI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACLs** tab, in the **Action** list, click **Flush**.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Flush**.

Extended ACLs and Extended ACL6s

September 14, 2021

Extended ACLs and extended ACL6s provide parameters and actions not available with simple ACLs. You can filter data based on parameters such as source IP address, source port, action, and protocol. You can specify tasks to allow a packet, deny a packet, or bridge a packet.

Extended ACLs and ACL6s can be modified after they are created, and you can renumber their priorities to specify the order in which they are evaluated.

Note: If you configure both simple and extended ACLs, simple ACLs take precedence over extended ACLs.

The following actions can be performed on extended ACLs and ACL6s: Modify, Apply, Disable, Enable, Remove, and Renumber (the priority). You can display extended ACLs and ACL6s to verify their configuration, and you can display their statistics.

You can configure the Citrix ADC to log details for packets that match an extended ACL.

Applying Extended ACLs and Extended ACL6s: Unlike simple ACLs and ACL6s, extended ACLs and ACL6s created on the Citrix ADC do not work until they are applied. Also, if you make any changes to an extended ACL or ACL6, such as disabling the ACLs, changing a priority, or deleting the ACLs, you must

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

reapply the extended ACLs or ACL6s. You must reapply them after enabling logging. The procedure to apply extended ACLs or ACL6s reapplies all of them. For example, if you have applied extended ACL rules 1 through 10, and you then create and apply rule 11, the first 10 rules are applied afresh.

If a session has a DENY ACL related to it, that session is terminated when you apply the ACLs.

Extended ACLs and ACL6s are enabled by default. When they are applied, the Citrix ADC starts comparing incoming packets against them. However, if you disable them, they are not used until you reenable them, even if they are reapplied.

Renumbering the priorities of Extended ACLs and Extended ACL6s: Priority numbers determine the order in which extended ACLs or ACL6s are matched against a packet. An ACL with a lower priority number has a higher priority. It is evaluated before ACLs with higher priority numbers (lower priorities), and the first ACL to match the packet determines the action applied to the packet.

When you create an extended ACL or ACL6, the Citrix ADC automatically assigns it a priority number that is a multiple of 10, unless you specify otherwise. For example, if two extended ACLs have priorities of 20 and 30, respectively, and you want a third ACL to have a value between those numbers, you might assign it a value of 25. If you later want to retain the order in which the ACLs are evaluated but restore their numbering to multiples of 10, you can use the renumber procedure.

Configuring Extended ACLs and Extended ACL6s

Configuring an extended ACL or ACL6 on a Citrix ADC consists of the following tasks.

- **Create an extended ACL or ACL6.** Create an extended ACL or ACL6 to either allow, deny, or bridge a packet. You can specify an IP address or range of IP addresses to match against the source or destination IP addresses of the packets. You can specify a protocol to match against the protocol of incoming packets.
- (Optional) **Modify an extended ACL or ACL6**. You can modify extended ACLs or ACL6s that you previously created. Or, if you want to temporarily take one out of use you can disable it, and later reenable it.
- **Apply extended ACLs or ACL6s**. After you create, modify, disable or reenable, or delete an extended ACL or ACL6, you must apply the extended ACLs or ACL6s to activate them.
- (Optional) **Renumber the priorities of extended ACLs or ACL6s**. If you have configured ACLs with priorities that are not multiples of 10 and want to restore the numbering to multiples of 10, use the renumber procedure.

CLI procedures

To create an extended ACL by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **add ns acl** <aclname> <aclaction> [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive_integer>] [-**srcMac** <mac_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer>] [-**interface** <interface_name>] [-**icmpType** <positive_integer> [-**icmpCode** <positive_integer>]] [-**priority** <positive_integer>] [-**state** (ENABLED | DISABLED)] [-**logstate** (ENABLED | DISABLED) [-**ratelimit** <positive_integer>]]
- **show ns acl** [<aclName>]

To create an extended ACL6 by using the CLI:

At the command prompt, type:

- **add ns acl6** <acl6name> <acl6action> [-**srcIPv6** [<operator>] <srcIPv6Val>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIPv6** [<operator>] <destIPv6Val>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive_integer>] [-**srcMac** <mac_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer>] [-**interface** <interface_name>] [-**icmpType** <positive_integer> [-**icmpCode** <positive_integer>]] [-**priority** <positive_integer>] [-**state** (ENABLED | DISABLED)]
- **show ns acl6** [<aclName>]

To modify an extended ACL by using the CLI:

To modify an extended ACL, type the **set ns acl** command, the name of the extended ACL, and the parameters to be changed, with their new values.

To modify an extended ACL6 by using the CLI:

To modify an extended ACL6, type the **set ns acl6** command, the name of the extended ACL6, and the parameters to be changed, with their new values.

To disable or enable an extended ACL by using the CLI:

At the command prompt, type one of the following commands:

- **disable ns acl** <aclname>
- **enable ns acl** <aclname>

To disable or enable an extended ACL6 by using the CLI:

At the command prompt, type one of the following commands:

- **disable ns acl6** <aclname>
- **enable ns acl6** <aclname>

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To apply extended ACLs by using the CLI:

At the command prompt, type:

- **apply ns acls**

To apply extended ACL6s by using the CLI:

At the command prompt, type:

- **apply ns acls6**

To renumber the priorities of extended ACLs by using the CLI:

At the command prompt, type:

- **renumber ns acls**

To renumber the priorities of extended ACL6s by using the CLI:

At the command prompt, type:

- **renumber ns acls6**

GUI procedures

To configure an extended ACL by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, add a new extended ACL or edit an existing extended ACL. To enable or disable an existing extended ACL, select it, and then select **Enable** or **Disable** from the **Action** list.

To configure an extended ACL6s by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, add a new extended ACL6 or edit an existing extended ACL6. To enable or disable an existing extended ACL6, select it, and then select **Enable** or **Disable** from the **Action** list.

To apply extended ACLs by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Apply**.

To apply extended ACL6s by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Apply**.

To renumber the priorities of extended ACLs by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Renumber Priority (s)**.

To renumber the priorities of extended ACL6s by using the GUI:

- Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Renumber Priority (s)**.

Sample Configurations

The following table shows examples of configuring extended ACL rules through the command line interface: ACLs sample configurations.

Logging extended ACLs

You can configure the Citrix ADC to log details for packets that match extended ACLs.

In addition to the ACL name, the logged details include packet-specific information such as the source and destination IP addresses. The information is stored either in the syslog file or in the `nslog` file, depending on the type of global logging (`syslog or nslog`) enabled.

Logging must be enabled at both the global level and the ACL level. The global setting takes precedence.

To optimize logging, when multiple packets from the same flow match an ACL, only the first packet's details are logged, and the counter is incremented for every packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the source IP address, destination IP address, source port, destination port, and protocol parameters. To avoid flooding of log messages, the Citrix ADC performs internal rate limiting so that packets belonging to the same flow are not repeatedly logged. The total number of different flows that can be logged at any given time is limited to 10,000.

Note: You must apply ACLs after you enable logging.

CLI procedures

To configure extended ACL Logging by using the CLI:

At the command prompt, type the following commands to configure logging and verify the configuration:

- **set ns acl** <aclName> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive_integer>]

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **apply acls**
- **show ns acl** [<aclName>]

GUI procedures

To configure extended ACL Logging by using the GUI:

1. Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, open the extended ACL.
2. Set the following parameters:
    - **Log State**—Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured `syslog or auditlog` server.
    - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

Sample configuration

```
> set ns acl restrict -logstate ENABLED -ratelimit 120
Warning: ACL modified, apply ACLs to activate change

> apply ns acls
Done
```

Logging extended ACL6s

You can configure the Citrix ADC appliance to log details for packets that match an extended ACL6 rule. In addition to the ACL6 name, the logged details include packet-specific information, such as the source and destination IP addresses. The information is stored either in a syslog or `nslog` file, depending on the type of logging (`syslog or nslog`) that you have configured in the Citrix ADC appliance.

To optimize logging, when multiple packets from the same flow match an ACL6, only the first packet's details are logged. The counter is incremented for every other packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the following parameters:

- Source IP
- Destination IP
- Source port
- Destination port
- Protocol (TCP or UDP)

If an incoming packet is not from the same flow, a new flow is created. The total number of different flows that can be logged at any given time is limited to 10,000.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

CLI procedures

To configure logging for an extended ACl6 rule by using the CLI:

- To configure logging while adding the extended ACL6 rule, at the command prompt, type:
  - **add acl6** <acl6Name> <acl6action> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive_integer>]
  - **apply acls6**
  - **show acl6** [<acl6Name>]
- To configure logging for an existing extended ACL6 rule, at the command prompt, type:
  - **set acl6** <acl6Name> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive_integer>]
  - **show acl6** [<acl6Name>]
  - **apply acls6**

GUI procedures

To configure extended ACL6 Logging by using the GUI:

1. Navigate to **System** > **Network** > **ACLs** and, then click the **Extended ACL6s** tab.
2. Set the following parameters while adding, or modifying an existing extended ACL6 rule.
   - **Log State** —Enable or disable logging of events related to the extended ACL6s rule. The log messages are stored in the configured syslog or `auditlog` server.
   - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the **Log State** parameter.

Sample configuration

```
> set acl6 ACL6-1 -logstate ENABLED -ratelimit 120
Done

> apply acls6
Done
```

Displaying extended ACLs and extended ACL6s statistics

You can display statistics of extended ACLs and ACL6s.

The following table lists the statistics associated with extended ACLs and ACL6s, and their descriptions.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Statistic	Specifies
Allow ACL matches	Packets matching ACLs with processing mode set to ALLOW. The Citrix ADC processes these packets.
NAT ACL matches	Packets matching a NAT ACL, resulting in a NAT session.
Deny ACL matches	Packets dropped because they match ACLs with processing mode set to DENY.
Bridge ACL matches	Packets matching a bridge ACL, which in transparent mode bypasses service processing.
ACL matches	Packets matching an ACL.
ACL misses	Packets not matching any ACL.
ACL Count	Total number of ACL rules configured by users.
Effective ACL Count	Total number of effective ACL configured internally. For an extended ACL with a range of IP addresses, the Citrix ADC appliance internally creates an extended ACL for each IP address. For example, for an extended ACL with 1000 IPv4 addresses (range or dataset), the Citrix ADC internally created 1000 extended ACLs.

CLI procedures

To display the statistics of all extended ACLs by using the CLI:

At the command prompt, type:

- **stat ns acl**

To display the statistics of all extended ACL6s by using the CLI:

At the command prompt, type:

- **stat ns acl6**

GUI procedures

To display the statistics of an extended ACL by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Navigate to **System > Network > ACLs**, on the **Extended ACLs** tab, select the extended ACL, and click **Statistics**.

To display the statistics of an extended ACL6 by using the GUI:

- Navigate to **System > Network > ACLs**, on the **Extended ACL6s** tab, select the extended ACL, and click **Statistics**.

Stateful ACLs

A stateful ACL rule creates a session when a request matches the rule and allows the resulting responses even if these responses match a deny ACL rule in the Citrix ADC appliance. A stateful ACL offloads the work of creating more ACL rules/forwarding session rules for allowing these specific responses.

Stateful ACLs can be best used in an edge firewall deployment of a Citrix ADC appliance having the following requirements:

- The Citrix ADC appliance must allow requests initiated from internal clients and the related responses from the Internet.
- The appliance must drop the packets from the Internet that are not related to any client connections.

Before you begin

Before you configure stateful ACL rules, note the following points:

- The Citrix ADC appliance supports stateful ACL rules and stateful ACL6 rules.
- In a high availability setup, the sessions for a stateful ACL rule are not synchronized to the secondary node.
- You cannot configure an ACL rule as stateful if the rule is bound to any Citrix ADC NAT configuration. Some examples of Citrix ADC NAT configurations are:
  - RNAT
  - Large Scale NAT (large scale NAT44, DS-Lite, large scale NAT64)
  - NAT64
  - Forwarding session
- You cannot configure an ACL rule as stateful if TTL and Established parameters are set for this ACL rule.
- The sessions created for a stateful ACL rule continue to exist until time out irrespective of the following ACL operations:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

  - Remove ACL
  - Disable ACL
  - Clear ACL

- Stateful ACLs are not supported for the following protocols:
  - Active FTP
  - TFTP

Configure stateful IPv4 ACL rules

Configuring a stateful ACL rule consists of enabling the stateful parameter of an ACL rule.

To enable the stateful parameter of an ACL rule by using the CLI:

- To enable the stateful parameter while adding an ACL rule, at the command prompt, type:
  - **add acl** <lname> ALLOW -**stateful** (ENABLED | DISABLED)
  - **apply acls**
  - **show acl** <name>
- To enable the stateful parameter of an existing ACL rule, at the command prompt, type:
  - **set acl** <name> -**stateful** (ENABLED | DISABLED)
  - **apply acls**
  - **show acl** <name>

To enable the stateful parameter of an ACL rule by using the GUI:

1. Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab.
2. Enable the **Stateful** parameter while adding, or modifying an existing ACL rule.

Sample configuration

```
> add acl ACL-1 allow -srciP 1.1.1.1 -stateful Yes

Done

> apply acls

Done

> show acl

1)          Name: ACL-1

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
13      Action: ALLOW                              Hits: 0
14
15      srcIP = 1.1.1.1
16
17      destIP
18
19      srcMac:
20
21      Protocol:
22
23      Vlan:                                    Interface:
24
25      Active Status: ENABLED                    Applied Status: NOTAPPLIED
26
27      Priority: 10                              NAT: NO
28
29      TTL:
30
31      Log Status: DISABLED
32
33      Forward Session: NO
34
35      Stateful: YES
```

Configure stateful ACL6 rules

Configuring a stateful ACL6 rule consists of enabling the stateful parameter of an ACL6 rule.

To enable the stateful parameter of an ACL6 rule by using the CLI:

- To enable the stateful parameter while adding an ACL6 rule, at the command prompt, type:
  - **add acl6** <name> ALLOW -stateful (ENABLED | DISABLD)
  - **apply acls6**
  - **show acl6** <name>
- To enable the stateful parameter of an existing ACL6 rule, at the command prompt, type:
  - **set acl6** <name> -**stateful** (ENABLED | DISABLED)
  - **apply acls6**
  - **show acl6** <name>

To enable the stateful parameter of an ACL6 rule by using the GUI:

1. Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab.
2. Enable the **Stateful** parameter while adding, or modifying an existing ACL6 rule.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Sample configuration

```
>  add acl6 ACL6-1 allow -srcipv6 1000::1  – stateful Yes

Done

>  apply acls6

Done

> show acl6

1)    Name: ACL6-1

    Action: ALLOW                          Hits: 0

    srcIPv6 = 1000::1

    destIPv6

    srcMac:

    Protocol:

    Vlan:                                 Interface:

    Active Status: ENABLED                 Applied Status: NOTAPPLIED

    Priority: 10                           NAT: NO

    TTL:

    Forward Session: NO

    Stateful: YES
```

Dataset based extended ACLs

Many ACLs are required in an enterprise. Configuring and managing many ACLs is difficult and cumbersome when they require frequent changes.

A Citrix ADC appliance supports datasets in extended ACLs. Dataset is an existing feature of a Citrix ADC appliance. A dataset is an array of indexed patterns of types: number (integer), IPv4 address, or IPv6 address.

Dataset support in extended ACLs is useful for creating multiple ACL rules, which require common ACL parameters.

While creating an ACL rule, instead of specifying the common parameters, you can specify a dataset, which includes these common parameters.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Any changes made in the dataset are automatically reflected in the ACL rules that are using this dataset. ACLs with datasets are easier to configure and manage. They are also smaller and easier to read than the conventional ACLs.

Currently, the Citrix ADC appliance supports only the IPv4 address type dataset for extended ACLs.

Before you begin

Before configuring dataset based extended ACL rules, note the following points:

- Make sure that you are familiar with the dataset feature of a Citrix ADC appliance. For more information about datasets, see Pattern sets and data sets.
- The Citrix ADC appliance supports datasets only for IPv4 extended ACLs.
- The Citrix ADC appliance supports only the IPv4 type datasets for extended ACLs.
- The Citrix ADC appliance supports Dataset based extended ACLs for all set ups: standalone, high availability, and cluster.
- For an extended ACL with a range of IP addresses, the Citrix ADC appliance internally creates an extended ACL for each IP address. For example, for an IPv4 dataset based extended ACL with 1000 IPv4 addresses bound to the dataset, the Citrix ADC appliance internally created 1000 extended ACLs.
  - The Citrix ADC appliance supports a maximum of 10K extended ACLs. For an IPv4 dataset based extended ACL with a range of IP addresses bound to the dataset, the Citrix ADC appliance stops creating internal ACLs once the total number of extended ACLs reaches the maximum limit.
  - The following counters are present as part of the extended ACL statistics:
    - **ACL count**. Total number of ACL rules configured by users.
    - **Effective ACL count**. Total number of effective ACL rules that the Citrix ADC appliance configures internally.

    For more information, see Displaying extended ACL and extended ACL6s Statistics.
- The Citrix ADC appliance does not support `set` and `unset` operations for associating/dissociating datasets with the parameters of an extended ACL. You can set the ACL parameters to a dataset only during the `add` operation.

Configure dataset based extended ACLs

Configuring a dataset based extended ACL rule consists of the following tasks:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Add a dataset**. A dataset is an array of indexed patterns of types: number (integer), IPv4 address, or IPv6 address. In this task, you create a type of dataset, for example, a dataset of type IPv4.
- **Bind values to the dataset**. Specify a value or a range of values to the dataset. The specified values must be of the same type as the dataset type. For example, you can specify an IPv4 address or a range of IPv4 addresses to the dataset of type IPv4.
- **Add an extended ACL and set ACL paramters to the dataset**. Add an extended ACL and set the required ACL parameters to the dataset. This setting results in the parameters set to the values specified in the dataset.
- **Apply extended ACLs**. Apply the ACLs to activate any new or modified extended ACLs.

To add a policy dataset by using the CLI:

At the command prompt, type:

- **add policy dataset** <name> <type>
- **show policy dataset**

To bind a pattern to the data set by using the CLI:

At the command prompt, type:

- **bind policy dataset** <name> <value> [-endRange <string>]
- **show policy dataset**

To add an extended ACL and set the ACL paramters to the dataset by using the CLI:

At the command prompt, type:

- **add ns acl** <aclname> <aclaction> [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>] …
- **show acls**

To apply extended ACLs by using the CLI:

At the command prompt, type:

- **apply acls**

Sample configuration

In the following sample configuration of a dataset based extended ACL, an IPv4 dataset DATASET-ACL-1 is created. Two IPv4 addresses: 192.0.2.30 and 192.0.2.60, and two IPv4 address ranges: (198.51.100.15 - 45) and (203.0.113.60-90) are bound to DATASET-ACL-1. DATASET-ACL-1 is then specified to the srcIP and destIP parameters of the extended ACL ACL-1.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add policy dataset DATASET-ACL-1 IPV4

bind dataset DATASET-ACL-1 192.0.2.30

bind dataset DATASET-ACL-1 192.0.2.60

bind dataset DATASET-ACL-1 198.51.100.15 -endrange 198.51.100.45

bind dataset DATASET-ACL-1 203.0.113.60 -endrange 203.0.113.90

add ns acl ACL-1 ALLOW -srcIP DATASET-ACL-1 -destIP DATASET-ACL-1

apply acls
```

MAC Address Wildcard Mask for ACLs

September 14, 2021

A wildcard mask parameter has been introduced for extended ACLs and ACL6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of incoming packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask must meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- 010101010101

For an ACL, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the incoming packets.

To specify a range of source MAC addresses in an ACL rule by using the CLI:

At the command prompt, type:

```
1 -  add ns acl <name> <action> -srcMac <mac_addr> -srcMacMask <string>
2 -  show ns acl <aclname>
```

Example:

```
1 add ns acl ACL-1 ALLOW –protocol TCP –srcport 2000-3000 -srcMac 96:fa
     :95:1d:67:4a
2  –srcMacMask 000000111111
3 Done
```

To specify a range of source MAC addresses in an ACL6 rule by using the CLI:

At the command prompt, type:

```
1 -  add ns acl6 <name> <action> -srcMac <mac_addr> -srcMacMask <string>
2 -  show ns acl6 <acl6name>
```

Example:

```
1 > add ns acl6 ACL6-1 ALLOW -destIPv6 2001::45 -srcMac 96:fa:90:1d:67:4a
2  –srcMacMask 000000001111
3 Done
```

Blocking Traffic on Internal Ports

September 14, 2022

By default, a Citrix ADC appliance does not block some type of internal traffic even using ACL rules.

The following table lists the internal traffic types that a Citrix ADC appliance does not block even using ACL rules:

Citrix ADC Setup	Protocol	Destination Port	Destination IP address
All	TCP	3008–3011	NSIP or SNIP
All	TCP	179	NSIP or SNIP

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Citrix ADC Setup	Protocol	Destination Port	Destination IP address
All	UDP	520	NSIP or SNIP
High availability	UDP	3003	NSIP
High availability	TCP	22	NSIP
Cluster	UDP	7000	NSIP

This feature of not blocking the earlier mentioned types of traffic is specified by the default setting of the global Layer-3 `Implicit ACL Allow` (`implicitACLAllow`) parameter.

You can disable this parameter if you want to block the earlier mentioned traffic types using the ACL rules. An appliance in a high availability setup makes an exception for its partner (primary or secondary) node. It does not block traffic from that node.

To disable or enable this parameter by using the CLI:

At the command prompt, type:

set l3param -**implicitACLAllow** [ENABLED	DISABLED]

-
- **sh l3param**

Note: The parameter implicitACLAllow is enabled by default.

Example:

```
1 > set l3param –implicitACLAllow DISABLED
2 Done
```

IP Routing

September 14, 2021

Citrix ADC appliances support both dynamic and static routing. Because simple routing is not the primary role of a Citrix ADC, the main objective of running dynamic routing protocols is to enable route health injection (RHI), so that an upstream router can choose the best among multiple routes to a topographically distributed virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Most Citrix ADC implementations use some static routes to reduce routing overhead. You can create backup static routes and monitor routes to enable automatic switchover in the event that a static route goes down. You can also assign weights to facilitate load balancing among static routes, create null routes to prevent routing loops, and configure IPv6 static routes. You can configure policy based routes (PBRs), for which routing decisions are based on criteria that you specify.

Configuring Dynamic Routes

September 14, 2021

When a dynamic routing protocol is enabled, the corresponding routing process monitors route updates and advertises routes. Routing protocols enable an upstream router to use the equal cost multipath (ECMP) technique to load balance traffic to identical virtual servers hosted on two standalone Citrix ADC appliances. Dynamic routing on a Citrix ADC appliance uses three routing tables. In a high-availability setup, the routing tables on the secondary appliance mirror those on the primary.

For command reference guides and unsupported commands on dynamic routing protocol, see Dynamic Routing Protocol Command Reference Guides and Unsupported Commands.

The Citrix ADC supports the following protocols:

- Routing Information Protocol (RIP) version 2
- Open Shortest Path First (OSPF) version 2
- Border Gateway Protocol (BGP)
- Routing Information Protocol next generation (RIPng) for IPv6
- Open Shortest Path First (OSPF) version 3 for IPv6
- ISIS Protocol

You can enable more than one protocol simultaneously.

Routing Tables in Citrix ADC

In a Citrix ADC appliance, the Citrix ADC kernel routing table, the FreeBSD kernel routing table, and the NSM FIB routing table each hold a different set of routes and serve a different purpose. They communicate with each other by using UNIX routing sockets. Route updates are not automatically propagated from one routing table to another. You must configure propagation of route updates for each routing table.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

NS Kernel Routing Table

The NS kernel routing table holds subnet routes corresponding to the NSIP and to each SNIP and MIP. Usually, no routes corresponding to VIPs are present in the NS kernel routing table. The exception is a VIP added by using the add ns ip command and configured with a subnet mask other than 255.255.255.255. If there are multiple IP addresses belonging to the same subnet, they are abstracted as a single subnet route. In addition, this table holds a route to the loopback network (127.0.0.0) and any static routes added through the CLI (CLI). The entries in this table are used by the Citrix ADC in packet forwarding. From the CLI, they can be inspected with the show route command.

FreeBSD Routing Table

The sole purpose of the FreeBSD routing table is to facilitate initiation and termination of management traffic (telnet, ssh, etc.). In a Citrix ADC appliance, these applications are tightly coupled to FreeBSD, and it is imperative for FreeBSD to have the necessary information to handle traffic to and from these applications. This routing table contains a route to the NSIP subnet and a default route. In addition, FreeBSD adds routes of type WasCloned(W) when the Citrix ADC establishes connections to hosts on local networks. Because of the highly specialized utility of the entries in this routing table, all other route updates from the NS kernel and NSM FIB routing tables bypass the FreeBSD routing table. Do not modify it with the route command. The FreeBSD routing table can be inspected by using the netstat command from any UNIX shell.

Network Services Module (NSM) FIB

The NSM FIB routing table contains the advertisable routes that are distributed by the dynamic routing protocols to their peers in the network. It may contain:

- **Connected routes**. IP subnets that are directly reachable from the Citrix ADC. Typically, routes corresponding to the NSIP subnet and subnets over which routing protocols are enabled are present in NSM FIB as connected routes.
- **Kernel routes**. All the VIP addresses on which the -hostRoute option is enabled are present in NSM FIB as kernel routes if they satisfy the required RHI Levels. In addition, NSM FIB contains any static routes configured on the CLI that have the - advertise option enabled. Alternatively, if the Citrix ADC is operating in Static Route Advertisement (SRADV) mode, all static routes configured on the CLI are present in NSM FIB. These static routes are marked as kernel routes in NSM FIB, because they actually belong to the NS kernel routing table.
- **Static routes**. Normally, any static route configured in VTYSH is present in NSM FIB. If administrative distances of protocols are modified, this may not always be the case. An important point to note is that these routes can never get into the NS kernel routing table.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Learned routes**. If the Citrix ADC is configured to learn routes dynamically, the NSM FIB contains routes learned by the various dynamic routing protocols. Routes learned by OSPF, however, need special processing. They are downloaded to FIB only if the fib-install option is enabled for the OSPF process. This can be done from the router-config view in VTYSH.

Dynamic Routing in a High Availability Setup

In a high availability setup, the primary node runs the routing process and propagates routing table updates to the secondary node. The routing table of the secondary node mirrors the routing table on the primary node.

Non-Stop Forwarding

After failover, the secondary node takes some time to start the protocol, learn the routes, and update its routing table. But this does not affect routing, because the routing table on the secondary node is identical to the routing table on the primary node. This mode of operation is known as non-stop forwarding.

Black Hole Avoidance Mechanism

After failover, the new primary node injects all its VIP routes into the upstream router. However, that router retains the old primary node's routes for 180 seconds. Because the router is not aware of the failover, it attempts to load balance traffic between the two nodes. During the 180 seconds before the old routes expire, the router sends half the traffic to the old, inactive primary node, which is, in effect, a black hole.

To prevent this, the new primary node, when injecting a route, assigns it a metric that is slightly lower than the one specified by the old primary node.

Interfaces for Configuring Dynamic Routing

To configure dynamic routing, you can use either the GUI or a command-line interface. The Citrix ADC supports two independent command-line interfaces: the CLI and the Virtual Teletype Shell (VTYSH). The CLI is the appliance's native shell. VTYSH is exposed by ZebOS. The Citrix ADC routing suite is based on ZebOS, the commercial version of GNU Zebra.

> **Note:**
>
> Citrix recommends that you use VTYSH for all commands except those that can be configured only on the CLI. Use of the CLI should generally be limited to commands for enabling the routing

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> protocols, configuring host route advertisement, and adding static routes for packet forwarding.

Dynamic Routing Protocol Command Reference Guides and Unsupported Commands

The following table lists command reference guide links, for various dynamic routing protocols, and unsupported commands on the Citrix ADC appliance: Dynamic routing protocol reference guides and unsupported commands.

Configuring RIP

September 14, 2021

Routing Information Protocol (RIP) is a Distance Vector protocol. The Citrix ADC supports RIP as defined in RFC 1058 and RFC 2453. RIP can run on any subnet.

After enabling RIP, you need to configure advertisement of RIP routes. For troubleshooting, you can limit RIP propagation. You can display RIP settings to verify the configuration.

Enabling and Disabling RIP

Use either of the following procedures to enable or disable RIP. After you enable RIP, the Citrix ADC appliance starts the RIP process. After you disable RIP, the appliance stops the RIP process.

To enable or disable RIP routing by using the CLI:

At the command prompt, enter one of the following commands to enable or disable RIP:

- **enable ns feature RIP**
- **disable ns feature RIP**

To enable or disable RIP routing by using the GUI:

1. Navigate to **System** > **Settings**, in **Modes and Features** group, click **Change advanced features**.
2. Select or clear the **RIP Routing** option.

Advertising Routes

RIP enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertisement enables an upstream router to track network entities located behind the Citrix ADC.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure RIP to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting RIP Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given interface.

To limit RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# passive-interface VLAN0
```

Verifying the RIP Configuration

You can display the routing table and other RIP settings.

To view the RIP settings by using the VTYSH command line:

At the command prompt, type the following commands in the following order:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh rip	Display updated RIP routing table.
sh rip interface	Displays RIP information for the specified VLAN.

Example:

```
NS# VTYSH
NS# sh rip
NS# sh rip interface VLAN0
```

Configuring OSPF

October 28, 2021

The Citrix ADC supports Open Shortest Path First (OSPF) Version 2 (RFC 2328). The features of OSPF on the Citrix ADC are:

- If a vserver is active, the host routes to the vserver can be injected into the routing protocols.
- OSPF can run on any subnet.
- Route learning advertised by neighboring OSPF routers can be disabled on the Citrix ADC.
- The Citrix ADC can advertise Type-1 or Type-2 external metrics for all routes.
- The Citrix ADC can advertise user-specified metric settings for VIP routes. For example, you can configure a metric per VIP without special route maps.
- You can specify the OSPF area ID for the Citrix ADC.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- The Citrix ADC supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
  - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
  - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

Enabling and Disabling OSPF

To enable or disable OSPF, you must use either the CLI or the GUI. When OSPF is enabled, the Citrix ADC starts the OSPF process. When OSPF is disabled, the Citrix ADC stops the OSPF routing process.

To enable or disable OSPF routing by using the CLI:

At the command prompt, type one of the following commands:

1. **enable ns feature OSPF**
2. **disable ns feature OSPF**

To enable or disable OSPF routing by using the GUI:

1. Navigate to **System** > **Settings**, in **Modes and Features** group, click **Change advanced features**.
2. Select or clear the **OSPF Routing** option.

Advertising OSPF Routes

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure OSPF to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enters global configuration mode.
router OSPF	Start OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	Enable routing on an IP network.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# network 10.102.29.0/24 area 0
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting OSPF Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given VLAN.

To limit OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router OSPF	Start OSPF routing process and enters configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example:

```
>VTYSH
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# passive-interface VLAN0
```

Verifying the OSPF Configuration

You can display current OSPF neighbors, and OSPF routes.

To view the OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh OSPF neighbor	Displays current neighbors.
sh OSPF route	Displays OSPF routes.

Example:

```
>VTYSH
NS# sh ip OSPF neighbor
NS# sh ip OSPF route
```

Configuring Graceful Restart for OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

> **Note:**
>
> Graceful restart is not supported for high availability setups in INC mode.

To configure graceful restart for OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id	NS(config)# router-id 1.1.1.1	Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA setup.
ospf restart grace-period <1-1800>	NS(config)# ospf restart grace-period 170	Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.
ospf restart helper max-grace-period <1-1800>	NS(config)# ospf restart helper max-grace-period 180	This is an optional command to limit the maximum grace period for which the Citrix ADC appliance will be in the helper mode. If the Citrix ADC appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the Citrix ADC is not placed in helper mode.
router ospf	NS(config)# router ospf	Starts OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	NS(config-router)# network 192.0.2.0/24 area 0	Enables routing on an IP network.
capability restart graceful	NS(config-router)# capability restart graceful	Enables graceful restart on the OSPF routing process.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Example	Command Description
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring BGP

October 28, 2021

The Citrix ADC appliance supports BGP (RFC 4271). The features of BGP on the Citrix ADC are:

- The Citrix ADC advertises routes to BGP peers.
- The Citrix ADC injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The Citrix ADC generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.
- As-Override Support in Border Gateway Protocol

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

Prerequisites for IPv6 BGP

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Enable the IPv6 feature.

Enabling and Disabling BGP

To enable or disable BGP, you must use either the CLI or the GUI. When BGP is enabled, the Citrix ADC appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the CLI:

At the command prompt, type one of the following commands:

- enable ns feature BGP
- disable ns feature BGP

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To enable or disable BGP routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

Advertising IPv4 Routes

You can configure the Citrix ADC appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system.
Address-family ipv4	Enter address family configuration mode.
Neighbor < IPv4 address> activate	Exchange prefixes for the IPv4 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor 10.102.29.170 remote-as 100
NS(config-router)# Address-family ipv4
NS(config-router-af)# Neighbor 10.102.29.170 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Prerequisites for IPv6 BGP

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Enable the IPv6 feature.

Advertising IPv6 BGP Routes

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure BGP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv6 address> remote-as < as-number>	Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system.
Address-family ipv6	Enter address family configuration mode.
Neighbor < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor a1bc::102 activate
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
```

Verifying the BGP Configuration

You can use VTYSH to display BGP settings.

To view the BGP settings using the VTYSH command line

At the command prompt, type:

```
VTYSH
You are now in the VTYSH command prompt. An output similar to the
   following appears:
NS170#
At the VTYSH command prompt, type:
NS170# sh ip BGP
NS170# sh BGP
NS170# sh ip BGP neighbors
NS170# sh ip BGP summary
NS170# sh ip BGP route-map <map-tag>
```

As-Override Support in Border Gateway Protocol

As a part of BGP loop prevention functionality, if a router receives a BGP packet containing the router's Autonomous System Number (ASN) in the Autonomous Systems (AS) path, the router drops the packet. The assumption is that the packet originated from the router and has reached the place from where it originated.

If an enterprise has several sites with a same ASN, BGP loop prevention causes the sites with an identical ASN to not get linked by another ASN. Routing updates (BGP packets) are dropped when another site receives them.

To solve this issue, BGP AS-Override functionality has been added to the ZebOS BGP routing module of the Citrix ADC.

With AS-Override enabled for a peer device, when the Citrix ADC appliance receives a BGP packet for forwarding to the peer, and the ASN of the packet matches that of the peer, the appliance replaces the ASN of the BGP packet with its own ASN number before forwarding the packet.

You can enable AS-Override for a specific neighbor or a group of neighbors (peer group) by using the VTYSH command line.

To configure BGP AS-Override for a IPv4 neighbor by using the VTYSH command line:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor as-override	Enable BGP as-override for the specified neighbor.

```
1     > VTYSH NS# configure terminal
2     NS(config)# router BGP 200
3     NS(config-router)# Neighbor 192.0.2.100 remote-as 100
4     NS(config-router)# Neighbor 10.102.29.100 as-override
```

To configure BGP AS-Override for a IPv4 BGP peer group by using the VTYSH command line:

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor **peer-group**	Create a BGP peer group.
Neighbot **peer-group**	Associate neighbors to the specified peer group.
Neighbor remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

```
1     > VTYSH NS# configure terminal
2     NS(config)# router BGP 200
3     NS(config-router)# neighbor external-peers-1 peer-group
4     NS(config-router)# neighbor 192.0.2.101 peer-group external-peers-1
5     NS(config-router)# neighbor 192.0.2.102 peer-group external-peers-1
6     NS(config-router)# neighbor 192.0.2.103 peer-group external-peers-1
7     NS(config-router)# Neighbor external-peers-1 remote-as 100
8     NS(config-router)# Neighbor external-peers-1 as-override
```

To configure BGP AS-Override for an IPv6 neighbor by using the VTYSH command line:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor < IPv6 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor as-override	Enable BGP as-override for the specified neighbor.
Address-family ipv6	Enter address family configuration mode.
Neighbor < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the specified neighbor and the Citrix ADC by using the link local address.
Neighbor as-override	Enable BGP as-override for the specified neighbor.

```
> VTYSH NS# configure terminal
NS(config)# router BGP 200
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Neighbor a1bc::102 as-override
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor a1bc::102 activate
NS(config-router)# Neighbor a1bc::102 as-override
```

To configure BGP AS-Override for IPv6 peer group by using the VTYSH command line:

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor **peer-group**	Create a BGP peer group.
Neighbor **peer-group**	Associate a neighbor with the specified peer group.
Neighbor remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Specifies
Address-family ipv6	Enter address family configuration mode.
Neighbor activate	Exchange prefixes for the IPv6 router family between the neighbors of the specified peer group and the Citrix ADC by using the link local address.
Neighbor as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

```
> VTYSH NS# configure terminal
NS(config)# router BGP 200
NS(config-router)# neighbor external-peers-2 peer-group
NS(config-router)# neighbor 2001::1 peer-group external-peers-2
NS(config-router)# neighbor 2001::2 peer-group external-peers-2
NS(config-router)# Neighbor external-peers-2 remote-as 100
NS(config-router)# Neighbor external-peers-2 as-override
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor external-peers-2 activate
NS(config-router)# Neighbor external-peers-2 as-override
```

Graceful Restart

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

> **Note:**
>
> Graceful restart is not supported for high availability setups in INC mode.

Configuring Graceful Restart for BGP

To configure graceful restart for BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id	NS(config)# router-id 1.1.1.1	A router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same identifier must be specified on the other node in a high availability setup for graceful restart to work properly.
router bgp	NS(config)# router bgp 5	Enters BGP configuration mode.
bgp graceful-restart	NS(config)# bgp graceful-restart	Enables graceful restart on the BGP routing process.
bgp graceful-restart restart-time <1-1800>	NS(config-router)# bgp graceful-restart restart-time 170	Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes.
bgp graceful-restart stalepath-time <1-1800>	NS(config-router)# bgp graceful-restart stalepath-time 180	Specifies the time, in seconds, that the Citrix ADC appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.
neighbor remote-as	NS(config-router)# neighbor 192.0.2.30 remote-as 2	Establishes BGP peering with the specified neighbor router device.
neighbor capability graceful-restart	NS(config-router)# neighbor 192.0.2.30 capability graceful-restart	Enables graceful restart with the specified neighbor.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring Graceful Restart for IPv6 BGP

To configure graceful restart for IPv6 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id	NS(config)# router-id 1.1.1.1	Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability setup for graceful restart to work properly.
router bgp	NS(config)# router bgp 5	Enters configuration mode for BGP protocol.
bgp graceful-restart	NS(config)# bgp graceful-restart	Enables graceful restart on the BGP routing process.
bgp graceful-restart restart-time <1-1800>	NS(config-router)# bgp graceful-restart restart-time 170	Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes. The default value is 360 seconds.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Example	Command Description
bgp graceful-restart stalepath-time <1-1800>	NS(config-router)# bgp graceful-restart stalepath-time 180	Specifies the time, in seconds, that the Citrix ADC appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.
neighbor remote-as	NS(config-router)# neighbor 2001:db8::10 remote-as 2	Establishes BGP peering with the specified neighbor router device.
address-family ipv6	NS(config-router)#address-family ipv6	Enters address family configuration mode.
neighbor activate	NS(config-router-af)#neighbor 2001:db8::10 activate	Enables the exchange of address family routes with the specified neighbor router device.
neighbor capability graceful-restart	NS(config-router-af)#neighbor 2001:db8::10 capability graceful-restart	Enables graceful restart with the specified neighbor router device.
redistribute kernel	NS(config-router-af)#redistribute kernel	Redistributes kernel routes.
exit-address-family	NS(config-router-af)#exit-address-family	Exits address family configuration mode.

Configuring MD5 Authentication for IPv4 BGP

The Citrix ADC appliance supports MD5 authentication for Border Gateway Protocol (BGP). When authentication is enabled, any TCP segment belonging to BGP exchanged between the Citrix ADC appliance and its peer device is verified and accepted only if authentication is successful. For authentication to be successful, both the peers must be configured with the same MD5 password. If authentication fails, the BGP neighbor relationship is not being established. MD5 authentication support for BGP in the Citrix ADC appliance is compliant with RFC 2385.

Before you Begin

Before you start configuring BGP MD5 authentication, consider the following points:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Make sure that you understand the different components of BGP MD5 authentication, described in RFC 2385.
- BGP MD5 authentication is not supported for Citrix ADC admin partitions.
- BGP MD5 authentication is not supported for IPv6 BGP configurations.
- BGP MD5 authentication is supported for Citrix ADC cluster configurations as well as for high availability configurations.
- Because of the following issue in FreeBSD, Citrix recommends to set a low keep-live and hold-time values (for example, 5 and 15) and configure graceful restart for a BGP session in a Layer 2 high availability configuration. Otherwise, with MD5 authentication enabled, BGP might take a longer time to re-establish a connection with the neighbour after a failover.
  - Last ACK from FreeBSD does not contain md5 digest:
    * https://forums.freebsd.org/threads/11170/
    * http://support.pfsense.narkive.com/povrH5HI/bgp-md5-weird-behavior-when-connection-closes

Configuring MD5 Authentication for IPv4 BGP

To configure MD5 authentication for IPv4 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Displays VTYSH command prompt.
configure terminal	Enters global configuration mode.
**router bgp **	Enters configuration mode for BGP protocol. is a BGP autonomous system number and is a required parameter.
neighbor remote-as < AS-number >	Updates the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.
neighbor < neighbour IPv4 address > password < password in double quotes>	Configures MD5 authentication for the specified neighbour with the specified MD5 password. For MD5 authentication to be successful, you must configure the same MD5 password on the Citrix ADC appliance and the neighbour appliance.

```
1 > vtysh
2
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
ns# configure terminal

ns(config)#router bgp 5

ns(config-router)#neighbor 20.20.20.138 remote-as 1

ns(config-router)#neighbor 20.20.20.138 password “secret”

ns(config-router)#redistribute kernel

ns(config-router)#exit
```

Configuring IPv6 RIP

September 14, 2021

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6 RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

Prerequisites for IPv6 RIP

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the Citrix ADC appliance.
- Enable the IPv6 feature.

Advertising IPv6 RIP Routes

IPv6 RIP enables an upstream router to load balance traffic between two identical vservers hosted on two standalone Citrix ADC devices. Route advertisement enables an upstream router to track network entities located behind the Citrix ADC.

To configure IPv6 RIP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting IPv6 RIP Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given interface.

To limit IPv6 RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 rip
NS(config-router)# passive-interface VLAN0
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Verifying the IPv6 RIP Configuration

You can use VTYSH to display the IPv6 RIP routing table and IPv6 RIP information for a specified VLAN.

To view the IPv6 RIP settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 rip	Display updated IPv6 RIP routing table.
sh ipv6 rip interface	Display IPv6 RIP information for the specified VLAN.

Example:

```
NS# VTYSH
NS# sh ipv6 rip
NS# sh ipv6 rip interface VLAN0
```

Configuring IPv6 OSPF

October 28, 2021

IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the Citrix ADC appliance.
- Enable the IPv6 feature.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Advertising IPv6 Routes

IPv6 OSPF enables an upstream router to load balance traffic between two identical vservers hosted on two standalone Citrix ADC devices. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure IPv6 OSPF to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 OSPF
4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
```

Limiting IPv6 OSPF Propagations

If you need to troubleshoot your configuration, you use VTYSH to configure listen-only mode on any given VLAN.

To limit IPv6 OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Commands	Specifies
passive-interface < vlan_name >	Suppress routing updates on interfaces bound to the specified VLAN.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# passive-interface VLAN0
```

Verifying the IPv6 OSPF Configuration

You use VTYSH to display IPv6 OSPF current neighbors and IPv6 OSPF routes.

To view the IPv6 OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 OSPF neighbor	Display current neighbors.
sh ipv6 OSPF route	Display IPv6 OSPF routes.

Example:

```
>VTYSH
NS# sh ipv6 OSPF neighbor
NS# sh ipv6 OSPF route
```

OSPFv3 Authentication

To ensure the integrity, data origin authentication, and data confidentiality of OSPFv3 packets, OSPFv3 authentication must be configured on OSPFv3 peers.

The Citrix ADC appliance supports OSPFv3 authentication and is partially compliant with RFC 4552. OSPFv3 authentication is based on the two IPSec protocols: Authentication Header (AH) and Encapsulating Security Payload (ESP). The Citrix ADC appliance supports only the AH protocol for OSPFv3 authentication.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

OSPFv3 authentication uses manually defined IPSec Security Associations (SAs) between the OSPFv3 peers and does not rely on IKE protocol for forming dynamic SAs. Manual SAs define the security parameter Index (SPI) values, algorithms, and keys to be used between the peers. Manual SAs require no negotiation between the peers; therefore, the same SA must be defined on both the peers.

You can configure OSPFv3 authentication on a VLAN or for an OSPFv3 area. When you configure for a VLAN, the settings are applied to all the interfaces that are members of the VLAN. When you configure OSPFv3 authentication for an OSPF area, the settings are applied to all the VLANs in that area. The settings are in turn applied to all the interfaces that are members of these VLANs. These settings do not apply to member VLANs on which you have configured OSPFv3 authentication directly.

Consider the following points and limitations before configuring OSPFv3 authentication on a Citrix ADC appliance:

- Make sure that you understand the different components of OSPFv3 authentication, described in RFC 4552.
- Only Authentication Header protocol is supported for OSPFv3 authentication. Encapsulating Security Payload (ESP) is not supported.
- You must define an SA with the same setting on the peer interface.
- Rekeying of manual keys is not supported.

To configure OSPFv3 authentication on a VLAN by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: OSPFv3 authentication VLAN commands.

Example:

```
1 > VTYSH NS# configure terminal
2 NS(config)# interface vlan2
3 NS(config-if)# ipv6 ospf authentication ipsec spi 256 md5 123456789
     ABCDEF0123456789ABCDEF0
```

To configure OSPFv3 authentication on an OSPF area by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: OSPFv3 authentication OSPF area commands.

Example:

```
1 > VTYSH NS# configure terminal
2 ns(config)#router ipv6 ospf 30
3 ns(config-router)# area 1 authentication ipsec spi 256
     md5123456789ABCDEF0123456789ABCDEF0
```

Configuring Graceful Restart for IPv6 OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

> **Note:**
>
> Graceful restart is not supported for high availability setups in INC mode.

To configure graceful restart for IPv6 OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id id>	NS(config)#router-id 1.1.1.1	Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA set up.
IPv6ospf restart grace-period <1-1800>	NS(config)# IPv6ospf restart grace-period 170	Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Example	Command Description
IPv6 ospf restart helper max-grace-period <1-1800>	NS(config)# IPv6 ospf restart helper max-grace-period 180	This is an optional command to limit the maximum grace period for which the Citrix ADC appliance will be in the helper mode. If the Citrix ADC appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the Citrix ADC is not placed in helper mode.
interface	NS(config)#interface vlan3	Enters VLAN configuration mode.
ipv6 router ospf area tag	NS(config-if)#ipv6 router ospf area 0 tag 1	Starts IPv6 OSPF routing process on a VLAN.
exit	NS(config-if)#exit	Exits VLAN configuration mode.
router ipv6 ospf	NS(config)# router ipv6 ospf 1	Starts IPv6 OSPF routing process and enters configuration mode for the routing process.
capability restart graceful	NS(config-router)#capability restart graceful	Enables graceful restart on the IPv6 OSPF routing process.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring ISIS

September 14, 2021

The Citrix ADC appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS-IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP) networks.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:

- Make sure that you understand the ISIS protocol.
- For IPV6 routes, enable:
  - IPv6 protocol translation feature.
  - IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

Enabling ISIS

Use either of the following procedures to enable the ISIS routing feature on the Citrix ADC appliance.

To enable ISIS routing by using the CLI:

At the command prompt, type:

enable ns feature ISIS

To enable ISIS routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

Creating an ISIS Routing Process and Starting It on a VLAN

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Creates an ISIS routing process and configuration mode for the routing process.
net XX….XXXX.YYYY.YYYY.YYYY.00	Specifies a NET value for the routing process, where: ·**XX. .. .XXXX** is the Area Address (can be 1-13 bytes), ·**YYYY.YYYY.YYYY** is the System ID (6 bytes), ·**00** is the N-selector (1 byte).
is-type (level-1|level-1-2|level-2-only)	Sets the ISIS routing process to the specified level of routing. Default: level-1-2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Description
ns IPv6-routing	Starts the IPv6 dynamic routing daemon.
interface	Enters the VLAN configuration mode.
ip router ISIS	Enables the ISIS routing process on the VLAN for IPv4 route exchanges.
ipv6 router ISIS	Enables the ISIS routing process on the VLAN for IPv6 route exchanges.

Example:

```
> VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# net 15.aabb.ccdd.0097.00
NS(config-router)# is-type level-1
NS(config-router)# exit
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)#  ip router isis 11
NS(config-if)# ipv6 router isis 11
```

Advertising Routes

Route advertisement enables an upstream router to track network entities located behind the Citrix ADC appliance.

To configure ISIS to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Starts the ISIS routing instance and enter configuration mode for the routing process.
redistribute connected (level-1 or level-1-2 or level-2)	Redistributes connected routes, where: **level-1**: Redistribute connected routes into Level-1, **level-1-2**: Redistribute connected routes into Level-1 and Level-2, **level-2**: Redistribute connected routes into Level-2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Description
redistribute kernel (level-1 or level-1-2 or level-2)	Redistributes kernel routes, where: **level-1**: Redistribute kernel routes into Level-1, **level-1-2**: Redistribute kernel routes into Level-1 and Level-2, **level-2**: Redistribute kernel routes into Level-2.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# redistribute connected level-1
NS(config-router)# redistribute kernel level-1
```

Limiting ISIS Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router isis [tag]	Enters the configuration mode for the routing process.
passive-interface	Suppresses routing updates on interfaces bound to the specified VLAN.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# passive-interface VLAN0
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Verifying the ISIS Configuration

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Description
VTYSH	Displays the VTYSH command prompt.
show ip isis route	Displays updated IPv4 ISIS routing table.
show ipv6 isis route	Displays updated IPv6 ISIS routing table.
sh isis interface	Displays IPv6 ISIS information for the specified VLAN.

Example:

```
NS# VTYSH
NS#  show ip isis route
NS#  show ipv6 isis route
NS# sh isis interface VLAN0
```

Install Routes to the Citrix ADC Routing Table

November 29, 2022

The Citrix ADC appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line:

At the CLI, type the following commands as appropriate for the routes that you want to install:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns route-install Default	Install IPv4 default routes to the internal routing table.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Commands	Specifies
ns route-install RIP	Install IPv4 RIP specific routes to the internal routing table.
ns route-install BGP	Install IPv4 BGP specific routes to the internal routing table.
ns route-install OSPF	Install IPv4 OSPF specific routes to the internal routing table.
ns route-install IPv6 Default	Install IPv6 default routes to the internal routing table.
ns route-install IPv6 RIP	Install IPv6 RIP specific routes to the internal routing table.
ns route-install IPv6 BGP	Install IPv6 BGP specific routes to the internal routing table.
ns route-install IPv6 OSPF	Install IPv6 OSPF specific routes to the internal routing table.

Example:

```
>VTYSH
NS# configure terminal
NS# ns route-install Default
NS(config)# ns route-install RIP
NS(config)# ns route-install BGP
NS(config)# ns route-install OSPF
NS# ns route-install IPv6 Default
NS(config)# ns route-install IPv6 RIP
NS(config)# ns route-install IPv6 BGP
NS(config)# ns route-install IPv6 OSPF
```

Maximum number of ECMP routes supported in a Citrix ADC appliance

In a Citrix ADC appliance up to 32 ECMP (Equal Cost Multiple Path) routes are supported. The route selection is based on five tuples. For more information, see Route selection based on five tuples.

Advertisement of SNIP and VIP Routes to Selective Areas

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To advertise some SNIP addresses to selective areas, enabling DRADV mode or redistribute connect ZebOS operations cannot be used. This is because these operations send all the connected routes to ZebOS. Also, adding dummy static routes in ZebOS for the required subnets, or adding ACLs in ZebOS to filter unwanted connected routes, is a cumbersome and tedious task.

The Network Route and the Tag options address this issue. You can enable the Network Route option for only one SNIP address per subnet. The connected route for that SNIP address is sent as a kernel route to ZebOS.

For VIP and SNIP addresses, Tag, can be assigned an integer from 1 to 4294967295. This parameter can be set only when Host Route or Network Route is enabled for VIP or SNIP addresses. The tag value associated with VIP and SNIP addresses are also sent along with their routes to ZebOS. Tags with different values can be set for VIP and SNIP routes. These tag values can then be matched in route maps in ZebOS and advertised to selective areas.

Advertise SNIP Routes to Selective Areas

To configure the network route and tag parameters of a SNIP address by using the CLI:

At the command prompt, type:

- If adding a new SNIP address:
  - **add ns ip** <IPAddress>@ <netmask> -**type SNIP** -**networkroute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
  - **show ns ip** <IPAddress>
- If reconfiguring an existing SNIP address:
  - **set ns ip** <IPAddress>@ <netmask> -**type SNIP** - **networkroute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
  - **show ns ip** <IPAddress>

To configure the network route and tag parameters of a SNIP address by using GUI:

1. Navigate to **System**> **Network** > **IPs** > **IPV4s**.
2. Set the **Network Route** and **Tag** parameters while adding a Subnet IP (SNIP) address or modifying an existing Subnet IP address.

Advertise VIP Routes to Selective Areas

To configure the host route and tag parameters of a VIP address by using the CLI:

At the command prompt, type one of the following sets of commands.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- If adding a new VIP address:
  - **add ns ip** <IPAddress>@ <netmask> -**type VIP** -**hostRoute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
  - **show ns ip** <IPAddress>
- If reconfiguring an existing VIP address:
  - **set ns ip** <IPAddress>@ <netmask> -**type VIP** -**hostRoute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
  - **show ns ip** <IPAddress>

To configure the network route and tag parameters of a VIP address by using the GUI:

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Set the **Host Route** and **Tag** parameters while adding a VIP address or modifying an existing VIP address.

Configuring Bidirectional Forwarding Detection

September 14, 2021

Bidirectional Forwarding Detection (BFD) protocol is a mechanism for fast detection of failures of forwarding paths. BFD detects path failures in the order of milliseconds. BFD is used with dynamic routing protocols.

In BFD operation, routing peers exchange BFD packets at a negotiated interval. If a packet is not received from a peer within the negotiated interval plus grace interval, the peer is considered to be dead and a notification will be sent to the set of registered routing protocols. In turn, the routing protocols recalculate the best path and reprogram the routing table. BFD supports smaller time interval, when compared to the timers provided by the routing protocols, thus resulting in faster detection of failures.

The Citrix ADC appliance supports BFD for the following routing protocols: BGP (IPv4 and IPv6), OSPFv2 (IPv4), and OSPFv3 (IPv6). BFD support in the Citrix ADC appliance is compliant with RFCs 5880, 5881, and 5883.

Points to Consider for Configuring Bidirectional Forwarding Detection

Before you start configuring BFD, consider the following points:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Make sure that you understand the different components of BFD, described in RFCs 5880, 5881, and 5883.
- BFD on a Citrix ADC appliance is supported for the following routing protocols:
  - BGP (IPv4 and IPv6)
  - OSPFv2 (IPv4)
  - OSPFv3 (IPv6)
- BFD on a Citrix ADC appliance is not supported for the following routing protocols:
  - ISIS
  - RIP (IPv4)
  - RIPng (IPv6)
- The following BFD features are not supported on a Citrix ADC appliance:
  - BFD Echo mode
  - BFD Authentication
  - BFD Demand asynchronous mode
- The minimum values for BFD interval and BFD Rx timers are 100 milliseconds.
- When BFD is used in a topology with shared IP addresses (for example, Layer 2 high availability setup with SNIP addresses or a cluster setup with striped IP addresses), BFD brings down the active sessions during a failover because the BFD failure detection time (order of milliseconds) is lesser than the HA failover detection interval (3–4 seconds). Therefore, Citrix recommends usage of Graceful restart in layer-2 HA topologies as the routes are retained during the failover process.

Configuration Steps

Configuring BFD on a Citrix ADC appliance consists of the following tasks:

- Configure BFD Parameters
- Configure BFD Support for Dynamic Routing Protocols

Configure BFD Parameters

The Citrix ADC appliance provides separate BFD session parameters for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. If you do not configure BFD parameters for a type of session, the default values are applied for that session.

The default value of each BFD parameter is same for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. The following table displays the default value of each BFD parameter.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

BFD Parameter Name	Default Value
Interval	750 milliseconds
Minimum Rx	500 milliseconds
Multiplier	3

> **IMPORTANT:**
>
> Mellanox NICs in a Citrix appliance take around 1500 ms to initialize. You must set the BFD timers to more than 1500 ms for a Citrix ADC appliance with Mellanox NICs. Citrix recommends setting the BFD timers to 3000 ms:
>
> - Interval Tx = 600 ms
> - Minimum Rx = 600 ms
> - Multipler = 5

Configuring BFD Parameters for a Single Hop Session

To configure BFD parameters for a single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`interface vlan ID>`	Enter the interface configuration mode.
`bfd singlehop-peer interval <num> minrx <num> multiplier <num>`	Configure the BFD parameters on the specified interface.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)# interface vlan3

ns(config-if)# bfd singlehop-peer interval 200 minrx 200 multiplier 5

ns(config-if)# exit
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring BFD Parameters for IPv4 Multiple Hop Sessions

To configure BFD parameters for IPv4 multiple hop sessions by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`bfd multihop-peer <ipv4addr> interval <num> minrx <num> multiplier <num>`	Configure the BFD parameters for IPv4 multiple hops sessions.

Sample configuration:

```
1      > vtysh
2
3      ns# configure terminal
4
5      ns(config)# bfd multihop-peer 20.20.20.138 interval 300 minrx 300
          multiplier 5
6
7      ns(config)# exit
```

Configuring BFD Parameters for IPv6 Multiple Hop Sessions

To configure BFD parameters for IPv6 multiple hop sessions by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`bfd multihop-peer ipv6 <ipv6addr> interval <num> minrx <num> multiplier <num>`	Configure the BFD parameters for IPv6 multiple hops sessions.

Sample configuration:

```
1      > vtysh
2
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx
    500 multiplier 5

ns(config)# exit
```

Configure BFD Support for Dynamic Routing Protocols

You can enable BFD for a dynamic routing protocol for a type of session with a peer. For example, single hop and multiple hops. The Citrix ADC appliance applies the relevant BFD parameter settings to the session.

Configuring BFD for an IPv4 BGP Single Hop Session

To configure BFD for an IPv4 BGP single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
vtysh	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router bgp <asnumber>	BGP autonomous system. asnumber is a required parameter.
neighbor <ipv4addr> remote-as <num>	Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.
neighbor <ipv4addr> fall-over bfd	Enable BFD for the specified neighbor.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)#router bgp 1

ns(config-router)#neighbor 20.20.20.138 remote-as 1

ns(config-router)#neighbor 20.20.20.138 fall-over bfd

ns(config-router)#redistribute kernel

ns(config-router)#exit
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring BFD for an IPv4 BGP Multiple Hop Session

To configure BFD for an IPv4 BGP multiple hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router bgp <asnumber>`	BGP autonomous system. `asnumber` is a required parameter.
`neighbor <ipv4addr> remote-as <num>`	Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.
`neighbor <ipv4addr> fall-over bfd multihop`	Enable BFD for the specified neighbor.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)#router bgp 1

ns(config-router)#neighbor 20.20.20.138 remote-as 1

ns(config-router)#neighbor 20.20.20.138 fall-over bfd multihop

ns(config-router)#redistribute kernel

ns(config-router)#exit
```

Configuring BFD for an IPv6 BGP Single Hop Session

To configure BFD for an IPv6 BGP single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Specifies
`router bgp <asnumber>`	BGP autonomous system. `asnumber` is a required parameter.
`neighbor <ipv6addr> remote-as <num>`	Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.
`neighbor <ipv6addr> fall-over bfd`	Enable BFD for the specified neighbor.
`address-family ipv6`	Enter address family configuration mode.
`neighbor <ipv6addr> activate`	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.

Sample configuration:

```
> vtysh

ns# configure terminal ns(config)#router bgp 1

ns(config-router)#neighbor 30fe:123::124 remote-as 1

ns(config-router)#neighbor 30fe:123::124 fall-over bfd

ns(config-router)#address-family ipv6

ns(config-router-af)#neighbor 30fe:123::124 activate

ns(config-router-af)#redistribute kernel

ns(config-router-af)#exit
```

Configuring BFD for an IPv6 BGP Multiple Hop Session

To configure BFD for an IPv6 BGP multiple hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router bgp <asnumber>`	BGP autonomous system. `asnumber` is a required parameter.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Specifies
`neighbor <ipv6addr> remote-as <num>`	Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.
`neighbor <ipv6addr> fall-over bfd multihop`	Enable BFD for the specified neighbor.
`address-family ipv6`	Enter address family configuration mode.
`neighbor <ipv6addr> activate`	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link-local address.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx 500
    multiplier 5

ns(config)#router bgp 1

ns(config-router)#neighbor 20fe:125::138 remote-as 1

ns(config-router)#neighbor 20fe:125::138 fall-over bfd multihop

ns(config-router)#address-family ipv6

ns(config-router-af)#neighbor 20fe:125::138 activate

ns(config-router-af)#redistribute kernel

ns(config-router-af)#end
```

Configuring BFD for OSPFv2 (IPv4) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv2 protocol.

To configure BFD for OSPFv2 on all interfaces by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router ospf <process tag>`	Enter OSPFv2 configuration mode.
`bfd all-interfaces`	Enable BFD on all interfaces that use OSPFv2.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)#router ospf 1

ns(config-router)#bfd all-interfaces

ns(config-router)#redistribute kernel

ns(config-router)#exit
```

To configure BFD for OSPFv2 on a specific interface by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`interface` `<vlan ID>`	Enter the interface configuration mode.
`ip ospf bfd`	Enable BFD on the specified interface that uses OSPFv2.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)# interface vlan5

ns(config-if)# ip ospf bfd

ns(config-if)# exit
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring BFD for OSPFv3 (IPv6) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv3 protocol.

To configure BFD for OSPFv3 on all interfaces by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`router ipv6 ospf <process tag>`	Enter OSPFv3 configuration mode.
`bfd all-interfaces`	Enable BFD on all interfaces that use OSPFv3.

Sample configuration:

```
> vtysh

ns# configure terminal

ns(config)#router ipv6 ospf 10

ns(config-router)#bfd all-interfaces

ns(config-router)#redistribute kernel

ns(config-router)#exit
```

To configure BFD for OSPFv3 on a specific interface by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
`vtysh`	Display VTYSH command prompt.
`configure terminal`	Enter global configuration mode.
`interface` `<vlan ID>`	Enter the interface configuration mode.
`ipv6 ospf bfd`	Enable BFD on the specified interface that uses OSPFv3.

Sample configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> vtysh

ns# configure terminal

ns(config)# interface vlan15

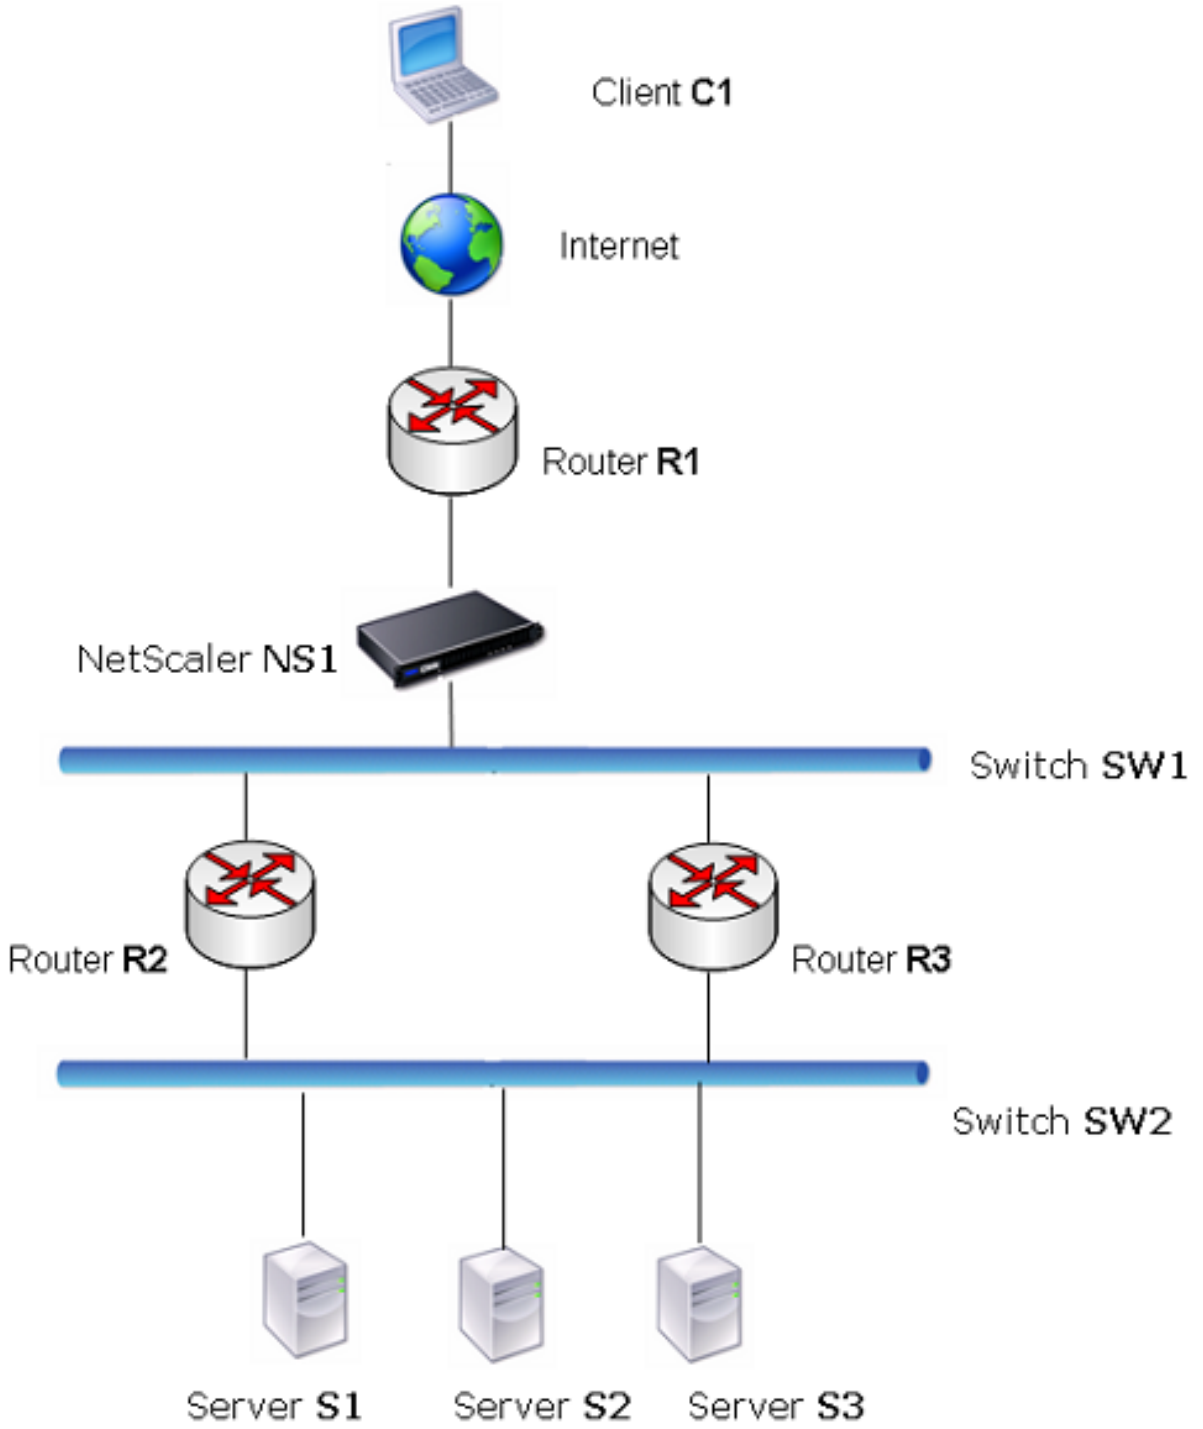
ns(config-if)# ipv6 ospf bfd

ns(config-if)# exit
```

Configuring Static Routes

September 14, 2021

Static routes are manually created to improve the performance of your network. You can monitor static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.



Monitored Static Routes. If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the Citrix ADC appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are transmitted and received by the Citrix ADC. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

Note: In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes.

Consider the following simple topology, in which a Citrix ADC is load balancing traffic to a site across multiple servers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Router R1 moves traffic between the client and the Citrix ADC appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers'

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the Citrix ADC points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the Citrix ADC marks it as DOWN. The Citrix ADC now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The Citrix ADC supports monitoring of IPv4 and IPv6 static routes. You can configure the Citrix ADC to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the Citrix ADC to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

Weighted Static Routes. When the Citrix ADC appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The Citrix ADC then uses both the weight and the hashed value for balancing the load.

Null Routes. If the route chosen in a routing decision is inactive, the Citrix ADC appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

Configuring IPv4 Static Routes

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

CLI procedures

To create a static route by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- add route <network> <netmask> <gateway>[-cost <positive_integer>] [-advertise (DISABLED | ENABLED)]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example:

```
> add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise
   ENABLED
 Done
```

To create a monitored static route by using the CLI:

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- add route <network> <netmask> <gateway> [-distance <positive_integer>] [-weight <positive_integer>][-msr (ENABLED | DISABLED) [-monitor <string>]]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example:

```
> add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6
    -msr ENBLED -monitor PING
 Done
```

To create a null route by using the CLI:

At the command prompt type:

- add route <network> <netmask> null
- show route <network> <netmask>

Example:

```
> add route 10.102.29.0 255.255.255.0 null
 Done
```

To remove a static route by using the CLI:

At the command prompt, type:

rm route <network> <netmask> <gateway>

Example:

```
> rm route 10.102.29.0 255.255.255.0 10.102.29.3
 Done
```

GUI procedures

To configure a static route by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Navigate to System > Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, delete the static route.

Configuring IPv6 Static Routes

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

CLI procedures

To create an IPv6 route by using the CLI:

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

- add route6 <network> <gateway> [-vlan <positive_integer>]
- show route6 [<network> [<gateway>]

Example:

```
1 > add route6 ::/0 FE80::67 -vlan 5
2  Done
```

To create a monitored IPv6 static route by using the CLI:

At the command prompt, type the following commands to create a monitored IPv6 static route and verify the configuration:

- add route6 <network> <gateway> [-msr (ENABLED | DISABLED) [-monitor <string>]
- show route6 [<network> [<gateway>]

Example:

```
1 > add route6 ::/0 2004::1 -msr ENABLED -monitor PING
2  Done
```

To remove an IPv6 route by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

rm route6 <network> <gateway>

Example:

```
> rm route6 ::/0 FE80::67
 Done
```

GUI procedures

To configure an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPV6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPV6 tab, delete the IPv6 route.

Route Health Injection Based on Virtual Server Settings

September 14, 2021

The following option and parameter are introduced for controlling the Route Health Injection (RHI) functionality of the Citrix ADC appliance for advertising the route of a VIP address.

- **VSVR_CNTRLD**. It is an option for the (Vserver RHI Level) parameter of a VIP address. When this option is set to the Vserver RHI Level parameter, the RHI behavior for advertising the route of the VIP address depends on the RHI STATE parameter setting on all the associated virtual servers of the VIP address along with their states.
- **RHI STATE**. It is a parameter of virtual server. You can set the RHI STATE parameter to either PASSIVE or ACTIVE. By default, the RHI STATE parameter is set to PASSIVE.

For a VIP address, when RHI (Vserver RHI Level) parameter is set to VSVR_CNTRLD, the following are different RHI behaviours for the VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address:

- If you set RHI STATE to PASSIVE on all virtual servers, the Citrix ADC always advertises the route for the VIP address.
- If you set RHI STATE to ACTIVE on all virtual servers, the Citrix ADC advertises the route for the VIP address if at least one of the associated virtual servers is in UP state.
- If you set RHI STATE to ACTIVE on some and PASSIVE on others, the Citrix ADC advertises the route for the VIP address if at least one of the associated virtual servers, whose RHI STATE set to ACTIVE, is in UP state.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Following table displays the sample RHI behaviour for a VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address. The Citrix ADC appliance has two virtual servers V1 and V2 associated with the VIP address:

Associated virtual servers for a VIP	State 1	State 2	State 3	State 4
RHI State set to PASSIVE on all virtual servers				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	Yes
RHI State set to ACTIVE on all virtual servers				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	No
RHI State set to ACTIVE on one virtual server and PASSIVE on the other				
V1 (RHI State = ACTIVE)	UP	UP	DOWN	DOWN
V2 (RHI State = PASSIVE)	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	No	No

To configure RHI for a VIP address, to be based on the RHI (RHI State) parameter setting of the associated virtual servers, perform the following steps:

- Set the RHI (Vserver RHI Level) parameter to VSVR_CNTRLD for the VIP address.
- Set the RHI State parameter for each virtual server associated with the VIP address.

To set the vServer RHI Level for a VIP address by using the CLI:

At the command prompt, type:

- **set ns ip** <IPAddress> [-**vserverRHILevel** <vserverRHILevel>]

To set the RHI State parameter of a virtual server by using the CLI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

At the command prompt, type:

- **set lb vserver** <name> [-**RHIstate** (**PASSIVE** | **ACTIVE**)]

To set the vServer RHI Level for a VIP address by using GUI

1. Navigate to **System** > **Network** > **IPs**.
2. Select a VIP address, and then click **Edit**.
3. Set the **Vserver RHI Level** parameter to **VSVR_CNTRLD**, and then click **OK**.

To set the RHI State parameter of a virtual server by using GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Select a load balancing virtual server, and then click **Edit**.
3. Set the **RHI State** parameter, and then click **OK**.

Configuring Policy-Based Routes

September 14, 2021

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the Citrix ADC appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the Citrix ADC applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the Citrix ADC to route the packet. These actions are known as "processing modes."The processing modes are:

- **ALLOW.** The appliance sends the packet to the designated next-hop router.
- **DENY.** The Citrix ADC applies the routing table for normal destination-based routing.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Policy-Based Routes (PBR) for IPv4 Traffic

September 14, 2021

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

Creating or Modifying a PBR

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the Citrix ADC appliance evaluates PBRs. When you create a PBR without specifying a priority, the Citrix ADC automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the Citrix ADC performs an action. If the packet does not match the condition defined by the PBR, the Citrix ADC compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the Citrix ADC and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

CLI procedures

To create a PBR by using the CLI:

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]

- show ns pbr

Example:

```
> add ns pbr pbr1  allow -srcip 10.102.37.252 -destip 10.10.10.2 -
   nexthop 10.102.29.77
 Done
```

To modify the priority of a PBR by using the CLI:

At the command prompt, type the following commands to modify the priority and verify the configuration:

- set ns pbr <name> [-action (ALLOW | DENY)] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]
- show ns pbr [<name>]

Example:

```
> set ns pbr pbr1 -priority 23
 Done
```

To remove one or all PBRs by using the CLI:

At the command prompt, type one of the following commands:

- rm ns pbr <name>
- clear ns pbrs

Example:

```
> rm ns pbr pbr1
 Done

> clear ns PBRs
 Done
```

GUI procedures

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To remove one or all PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, delete the PBR.

Applying a PBR

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1 - p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must follow this procedure after disabling a PBR.

Note: PBRs created on the Citrix ADC appliance do not work until they are applied.

To apply a PBR by using the CLI:

At the command prompt, type:

apply ns PBRs

To apply a PBR by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Apply.

Enabling or Disabling PBRs

By default, the PBRs are enabled. This means that when PBRs are applied, the Citrix ADC appliance automatically compares incoming packets against the configured PBRs. If a PBR is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs are applied. After the PBRs are applied, the Citrix ADC does not compare incoming packets against disabled PBRs.

To enable or disable a PBR by using the CLI:

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

Example:

```
> enable ns PBR pbr1
 Done
> show ns PBR pbr1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
1)      Name: pbr1
        Action: ALLOW                           Hits: 0
        srcIP = 10.102.37.252
        destIP = 10.10.10.2
        srcMac:                                 Protocol:
        Vlan:                                   Interface:
        Active Status: ENABLED                  Applied Status: APPLIED
        Priority: 10
        NextHop: 10.102.29.77

 Done

> disable ns PBR pbr1
Warning: PBR modified, use 'apply pbrs' to commit this operation

> apply pbrs
 Done

> show ns PBR pbr1
1)      Name: pbr1
        Action: ALLOW                           Hits: 0
        srcIP = 10.102.37.252
        destIP = 10.10.10.2
        srcMac:                                 Protocol:
        Vlan:                                   Interface:
        Active Status: DISABLED                 Applied Status:
           NOTAPPLIED
        Priority: 10
        NextHop: 10.102.29.77
Done
```

To enable or disable a PBR by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Enable or Disable.

Renumbering PBRs

You can automatically renumber the PBRs to set their priorities to multiples of 10.

To renumber PBRs by using the CLI:

At the command prompt, type:

- renumber ns pbrs

To renumber PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, in the Action list, select Renumber Priority (s).

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Use Case - PBR with Multiple Hops

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on Citrix ADC appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The Citrix ADC appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.
- Specifying an LLB virtual server for which the LB method is not set to one of the following:
  - ROUNDROBIN
  - DESTINATIONIPHASH
  - SOURCEIPHASH
  - SRCIPDESTIPHASH
  - LEASTPACKETS
  - LEASTBANDWIDTH
  - LTRM
  - CALLIDHASH
  - CUSTOM LOAD
- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
  - DESTIP
  - SOURCEIP
  - SRCDSTIP

The following table lists the names and values of the entities configured on the Citrix ADC appliance:

Entity Type	Name	IP Address
Link load balancing virtual server	LLB1	NA

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity Type	Name	IP Address
Services (next hops)	Router1	1.1.1.254
	Router2	2.2.2.254
	Router3	3.3.3.254
PBRs	PBR1	NA
	PBR2	NA

Table 1. Sample Values for Creating Entities

To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

Example:

```
> add service Router1 1.1.1.254 ANY *
 Done
> add service Router2 2.2.2.254 ANY *
 Done
> add service Router3 3.3.3.254 ANY *
 Done
```

To create a service by using the GUI:

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the CLI:

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
> add lb vserver LLB1 ANY
 Done
> bind lb vserver LLB1 Router1 Router2 Router3
 Done
```

To create a link load balancing virtual server and bind a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
   Note: Make sure that
   Directly Addressable is unchecked.
2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the CLI:

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

Example:

```
> add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
 Done
> add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
 Done
```

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR.

Policy-Based Routes (PBR6) for IPv6 Traffic

September 14, 2021

Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Creating or Modifying a PBR6

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the Citrix ADC appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the Citrix ADC automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the Citrix ADC performs an action. If the packet does not match the condition defined by the PBR6, the Citrix ADC compares the packet against the PBR6 with the next highest priority.

CLI procedures

To create a PBR6 by using the CLI:

At the command prompt, type:

- **add ns pbr6** <name> <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]
- show ns pbr

To modify or remove a PBR6 by using the CLI:

To modify a PBR6, type the **set pbr6** <name> command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the CLI:

At the command prompt, type one of the following commands:

- **rm ns pbr6** <name>
- **clear ns pbr6**

GUI procedures

To create or modify a PBR6 by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To remove one or all PBR6s by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, delete the PBR6.

Applying PBR6s

You must apply a PBR6 to activate it. The following procedure reapplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6_1 - p6_10), and then you create another PBR6 (p6_11) and apply it, all of the PBR6s (p6_1 - p6_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

Note: PBR6s created on the Citrix ADC appliance do not work until they are applied.

To apply PBR6s by using the CLI:

At the command prompt, type:

- **apply ns PBR6**

To apply PBR6s by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Apply.

Enabling or Disabling a PBR6

By default, the PBR6s are enabled. This means that when PBR6s are applied, the Citrix ADC appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the Citrix ADC does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the CLI:

At the command prompt, type one of the following commands:

- **enable ns pbr** <name>
- **disable ns pbr** <name>

To enable or disable a PBR6 by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Enable or Disable.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Renumbering PBR6s

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the CLI:

At the command prompt, type:

- **renumber ns pbr6**

To renumber PBR6s by using the GUI:

Navigate to System > Network > PBRs, on the PBR6s tab, in the Action list, select Renumber Priority (s).

MAC Address Wildcard Mask for PBRs

September 14, 2021

A wildcard mask parameter has been introduced for extended PBRs and PBR6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of outgoing packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- 010101010101

For an PBR rule, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the outgoing packets.

To specify a range of source MAC addresses in a PBR rule by using the CLI:

At the command prompt, type:

- **add ns pbr** <name> <action> -**srcMac** <mac_addr> -**srcMacMask** <string>
- **show ns pbr** <pbrname>

Example:

```
1 > add ns pbr PBR-1 ALLOW -srcip 192.0.2.34 -srcMac 96:fa:95:1d:67:4a
      – srcMacMask 000000111111 -nexthop 198.51.100.1
2
3  Done
```

To specify a range of source MAC addresses in an PBR6 rule by using the CLI:

At the command prompt, type:

- **add ns pbr6** <name> <action> -**srcMac** <mac_addr> -**srcMacMask** <string>
- **show pbr6** <pbr6name>

Example:

```
1 > add ns pbr6 PBR6-1 ALLOW  – srcipv6 2001:db8:0::7 -srcMac 96:fa:95:1d
     :67:4a   – srcMacMask 000000001111 -nexthop 2001:db8:0::1
2  Done
```

Using NULL Policy Based Routes to Drop Outgoing Packets

September 14, 2021

Some situations might demand that the Citrix ADC appliance drops specific outgoing packets instead of routing them, for example, in testing cases and during deployment migration.

NULL policy based routes can be used to drop specific outgoing packets. A NULL PBR is a type of PBR that has the nexthop parameter set to NULL. The Citrix ADC appliance drops outgoing packets that match a NULL PBR.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configuring NULL PBRs for IPv4 Packets

To create a NULL PBR by using the CLI:

At the command prompt, type:

- **add ns pbr** <name> ALLOW [**-td** <positive_integer>] [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>] (-**nextHop NULL**) [**srcMac** <mac_addr> [-**srcMacMask** <string>]] [-**protocol** <protocol> | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer> | -**vxlan** <positive_integer>] [-**interface** <interface_name>] [-**priority** <positive_integer>] [-**msr** (**ENABLED** | **DISABLED**) [**-monitor** <string>]] [-**state** (**ENABLED** | **DISABLED**)[-**ownerGroup** <string>]
- **apply ns pbrs**
- **show ns pbr**<id>

To configure a NULL PBR by using the GUI:

Navigate to **System** > **Network**> **PBRs**, on the **PBRs** tab, add a **new NULL PBR**, or edit an existing NULL PBR.

Sample configuration

In the following sample configuration, NULL PBR6 PBR6-NULL-EXAMPLE-1 is configured for dropping any outgoing IPv6 packets from interface 1/5.

```
1 > add ns pbr PBR6-NULL-EXAMPLE-1 ALLOW  – nextHop NULL -interface 1/5
2  Done
3
4 > apply ns pbr6
5  Done
```

Traffic distribution in multiple routes based on five tuples information

September 14, 2021

In a load balancing setup, a Citrix ADC appliance can have multiple routes to send a packet to its destination. For example: to a server, and to a client.

A Citrix ADC appliance uses a hashing algorithm to select a route for sending the packet to its destination.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The hashing algorithm uses the following two tuples of a packet to calculate a hash, based on which the Citrix ADC appliance selects a route for the packet.

- Source IP address
- Destination IP address

The selection of routes based on two tuples information can cause an uneven distribution of traffic on the available routes. This uneven distribution of traffic leads to overloading of traffic in some routes.

To resolve this issue, from build 13.0 71.x, the Citrix ADC appliance uses the following five tuples information of a packet in the hashing algorithm to select a route for the packet:

- Source IP address (Client IP)
- Source Port (Client Port)
- Destination IP address(Service IP)
- Destination Port (Service Port)
- Protocol number

The selection of routes based on five tuples information ensures even distribution of traffic on the available routes. This even distribution of traffic prevents overloading of traffic in a route.

Consider an example of a load balancing setup where a client sends a request to the VIP address. The Citrix ADC appliance uses the following five tuples information to select a route to send the request packet to the load balanced server:

- Source IP address (Client IP address)
- Source Port (Client port)
- Destination IP address (Service IP address)
- Destination Port (Service port number)
- Protocol Number

Precedence regarding other route selection based Citrix ADC features

This section talks about the precedence of the route selection based on five tuples feature and other route selection related features in a Citrix ADC appliance.

- **Policy Based Routes (PBR)**. PBR rules always take precedence over route selection based on five tuples.
- **Mac Based Forwarding (MBF)**. In a load balancing configuration, MBF or route selection based on five tuples takes precedence in the following cases:
  - For a client initiated traffic to the VIP address of the load balancing configuration in the Citrix ADC appliance:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

    * Request traffic destined to a load balanced server. Route selection based on five tuples takes preference over MBF.
    * Response Traffic destined to the client. MBF takes preference over route selection based on five tuples.
  - For a server initiated traffic to the SNIP address in the Citrix ADC appliance:
    * Response Traffic destined to the client. Route selection based on five tuples takes preference over MBF.
    * Request traffic destined to a load balanced server. MBF takes preference over route selection based on five tuples.

Troubleshooting Routing Issues

September 14, 2021

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the Citrix ADC appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the show running command to get the running configuration for ns.conf and ZebOS.conf.
- Output of the History command, to determine whether any configuration changes were made when the issue arose.
- Output of the Top and ps -ax commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.
- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr_error.log and dr_info.log files from /var/log.
- Output of the date command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newnslog files.
- Configuration files, log files and command history details from upstream and downstream routers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Generic Routing FAQs

September 14, 2021

Users typically have the following questions about how to troubleshoot generic routing issues:

- How do I save the config files?

  The write command from VTYSH saves only ZebOS.conf. Run the save ns config command from CLI to save both ns.conf and ZebOS.conf files.

- If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

  The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.

- How do I block the advertisement of default routes?

  The default route is not injected into ZebOS.

- How do I view the debug output of networking daemons?

  You can write debugging output from networking daemons to a file by entering the following log file command from the global configuration view in VTYSH:

  ```
  ns(config)# log file /var/ZebOS.log
  ```

  You can direct debug output to the console by entering the terminal monitor command from VTYSH user view:

  ```
  ns# terminal monitor
  ```

- How do I collect cores of running daemons?

  You can use the gcore utility to collect cores of running daemons for processing by gdb. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

  ```
  gcore [-s] [-c core] [executable] pid
  ```

  The -s option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

  ```
  root@ns#gcore -s -c nsm.core /netscaler/nsm 342
  ```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- How do I run a batch of ZebOS commands?

  You can run a batch of ZebOS commands from a file by entering the VTYSH -f <file-name> command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

```
!
router bgp 234
network 1.1.1.1 255.255.255.0
!
route-map bgp-out2 permit 10
 set metric 9900
 set community 8602:300
!
```

Troubleshooting OSPF-Specific Issues

September 14, 2021

Before you start debugging any OSPF specific issue, you must collect information from the Citrix ADC appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. show ip ospf interface
3. show ip ospf neighbor detail
4. show ip route
5. show ip ospf route
6. show ip ospf database summary
   - If there are only few LSAs in the database, then enter show ip ospf database router, show ip ospf database A. network, show ip ospf database external, and other commands to get the full details of LSAs.
   - If there are a large number of LSAs in the database, enter the show ip ospf database self-originated command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
gcore -s -c xyz.core /netscaler/ospfd <pid>
```

Note: The gcore command is non-disruptive.

Collect additional information from the Citrix ADC as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:

   ```
   ns(config)# log file /var/ospf.log
   ```

2. Enable debugging ospf events and log them by using the following command:

   ```
   ns(config) #log file /var/ospf.log
   ```

   Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).

Internet Protocol version 6 (IPv6)

September 14, 2021

A Citrix ADC appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services.

The following table lists some of the IPv6 features that the Citrix ADC appliance supports.

Table 1. Some Supported IPv6 Features

IPv6 features
IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)
Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)
Management Applications (ping6, telnet6, ssh6)
Static Routing and Dynamic routing (OSPF, BGP, RIPng, and ISIS)
Port Based VLANs
Access Control Lists for IPv6 addresses (ACL6)
IPv6 Protocols (TCP6, UDP6, ICMP6)

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

IPv6 features
Server Side Support (IPv6 addresses for vservers, services)
USIP (Use source IP) and DSR (Direct Server Return) for IPv6
SNMP and CVPN for IPv6
HA with native IPv6 node address
IPv6 addresses for MIPs
Path-MTU discovery for IPv6

Implementing IPv6 Support

You must enable IPv6 feature on a Citrix ADC appliance before you can use or configure it. If IPv6 is disabled, the Citrix ADC does not process IPv6 packets. It displays the following warning when you run an unsupported command:

```
1 "Warning: Feature(s) not enabled [IPv6PT]"
```

Use either of the following procedures to enable or disable IPv6.

CLI procedures

To enable or disable IPv6 by using the CLI:

At the command prompt, type one of the following commands:

- enable ns feature ipv6pt
- disable ns feature ipv6pt

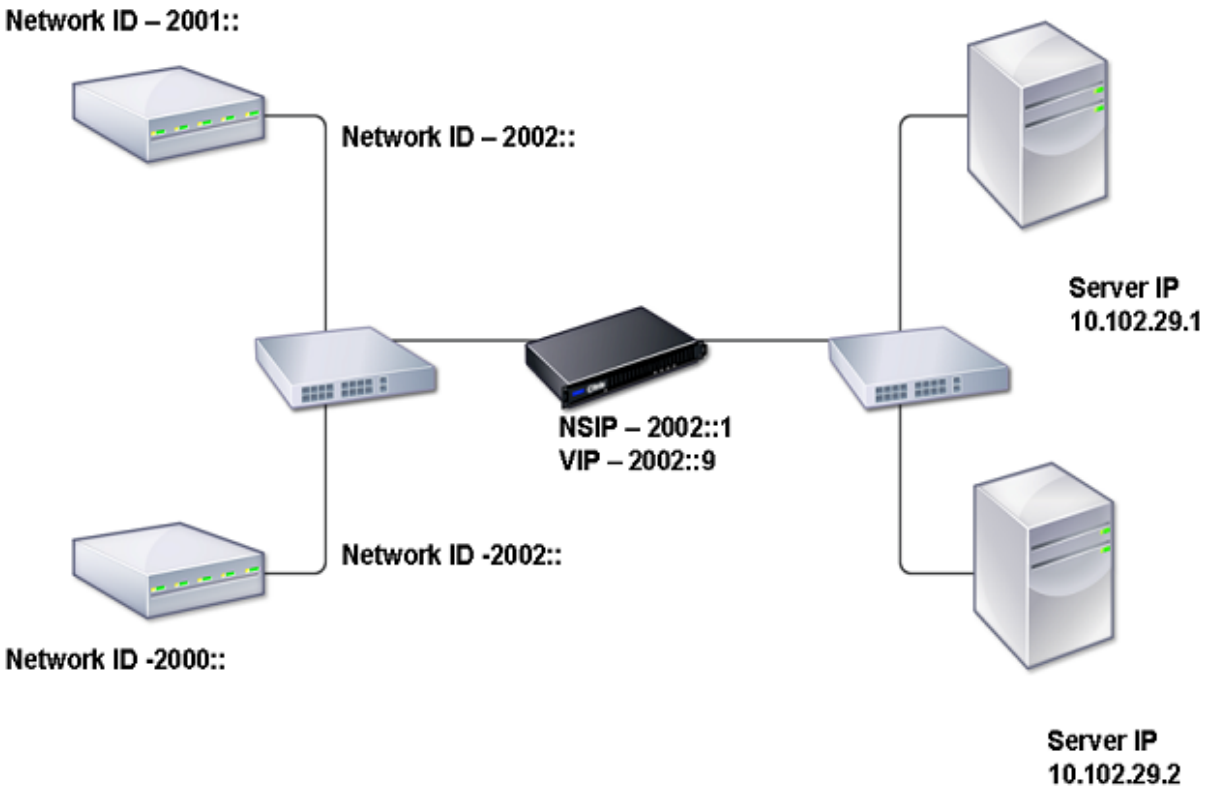
GUI procedures

To enable or disable IPv6 by using the GUI:

1. Navigate to **System** > **Settings**, in the **Modes and Features** group, click **Configure Advanced Features**.
2. Select or clear the **IPv6 Protocol Translation** option.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

VLAN Support



If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the Citrix ADC appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN. For more information about ND6 and VLANs, see Configuring Neighbor Discovery.

Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

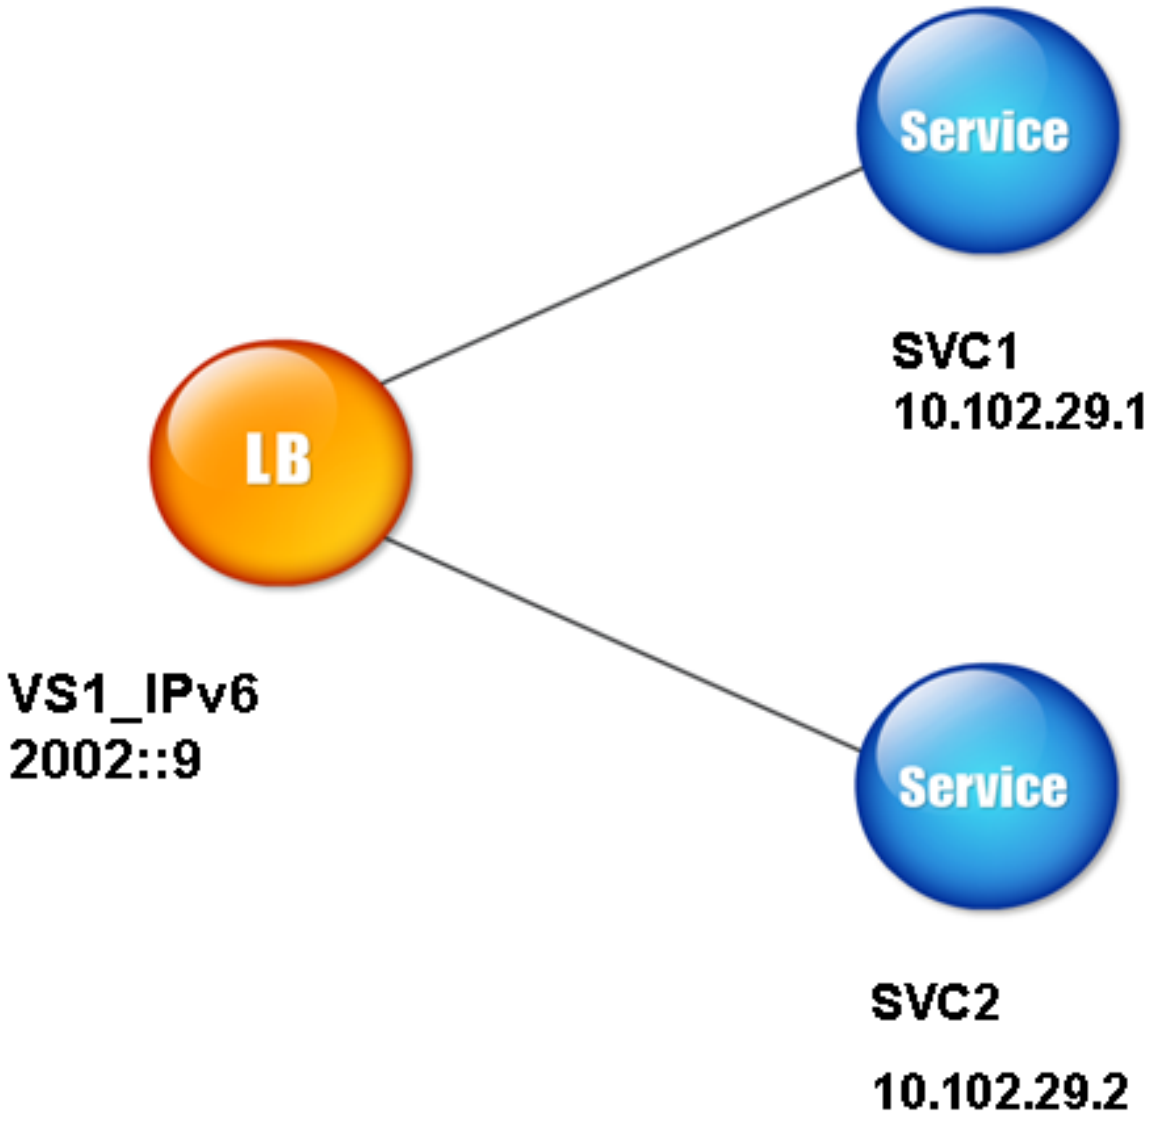
Simple Deployment Scenario

Following is an example of a simple load balancing set-up consisting of an IPv6 vserver and IPv4 services, as illustrated in the following topology diagram.

Figure 1. IPv6 Sample Topology

The following table summarizes the names and values of the entities that must be configured on the Citrix ADC.

Table 2. Sample Values for Creating Entities



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity type	Name	Value
LB Vserver	VS1_IPv6	2002::9
Services	SVC1	10.102.29.1
	SVC2	10.102.29.2

The following figure shows the entities and values of the parameters to be configured on the Citrix ADC.

Figure 2. IPv6 Entity Diagram

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB vserver.
3. Bind the services to the vserver.

CLI procedures

To create IPv4 services by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **add service** <Name> <IPAddress> <Protocol> <Port>
- **sh service** <Name>

Example:

```
> add service SVC1 10.102.29.1 HTTP 80
Done

>add service SVC2 10.102.29.2 HTTP 80
Done
```

To create IPv6 vserver by using the CLI:

At the command prompt, type:

- **add lb vserver** <Name> <IPAddress> <Protocol> <Port>
- **sh lb vserver** <Name>

Example:

```
> add lb vserver VS1_IPv6 2002::9 HTTP 80
Done
```

To bind a service to an LB vserver by using the CLI:

At the command prompt, type:

- **bind lb vserver** <name> <service>
- **sh lb vserver** <name>

Example:

```
> bind lb vserver VS1_IPv6 SVC1
Done
```

GUI procedures

To create IPv4 services by using the GUI:

Navigate to **Traffic Management** > **Load Balancing** > **Services**, click **Add**, and then set the following parameters:

- Service Name
- IP Address
- Protocol
- Port

To create IPv6 vserver by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, click **Add**, and select the **IPv6** check box.
2. Set the following parameters:
    - Name
    - Protocol
    - IP Address Type
    - IP Address
    - Port

To bind a service to an LB vserver by using the GUI:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. In the **Load Balancing Virtual Servers** page, select the vserver for which you want to bind the service (for example, VS1_IPv6).
3. Click **Open**.
4. In the **Configure Virtual Server (Load Balancing)** dialog box, on the **Services** tab, select the **Active** check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click **OK**.
6. Repeat steps 1-4 to bind the service (for example, SVC2 to the vserver).

Host Header Modification

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the vserver.

CLI procedures

To change the IPv6 address in the host header to an IPv4 address by using the CLI:

At the command prompt, type:

- **set ns ip6** <IPv6Address> -**map** <IPAddress>
- **sh ns ip6** <IPv6Address>

Example:

```
1 > set ns ip6 2002::9 -map 200.200.200.200
2 Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

GUI procedures

To change the IPv6 address in the host header to an IPv4 address by using the GUI:

1. Navigate to **System** > **Network** > **IPs** and, on the **IPV6s** tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Edit.
2. In the **Mapped IP** text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

VIP Insertion

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP. Then, you can enable VIP insertion to enable insertion of the IPv4 VIP address and port number in the HTTP requests sent to the servers.

CLI procedures

To configure a map IPv6 address by using the CLI:

At the command prompt, type:

set ns ip6 <IPv6Address> -**map** <IPAddress>

Example:

```
1 > set ns ip6 2002::9 -map 200.200.200.200
2  Done
```

To enable VIP insertion by using the CLI:

At the command prompt, type:

- **set lb vserver** <name> -**insertVserverIPPort** <Value>
- **sh lb vserver** <name>

Example:

```
1 > set lb vserver VS1_IPv6 -insertVserverIPPort ON
2  Done
```

GUI procedures

To configure a map IPv6 address by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Navigate to **System** > **Network** > **IPs**, on the **IPV6s** tab, select the IP address for which you want to configure a map IP address, for example, 2002:0:0:0:0:0:0:9, and click **Edit**.
2. In the **Mapped IP** text box, type the map IP address that you want to configure, for example, 200.200.200.200.

To enable VIP insertion by using the GUI:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select the virtual server that you want to enable port insertion, and click **Edit**.
2. In the **Advanced** tab, under **Traffic Settings**, in the **Vserver IP Port Insertion** drop-down list box, select **VIPADDR**.
3. In the **Vserver IP Port Insertion** text box, type the vip header.

Traffic Domains

September 14, 2021

> **Warning**
>
> Citrix recommends you to use Admin Partitions instead of using Traffic Domains. For more information, see Admin Partitioning page.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a Citrix ADC appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Benefits of using Traffic Domains

The main benefits of using traffic domains on a Citrix ADC appliance are the following:

- **Use of duplicate IP addresses in a Network**. Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a Citrix ADC appliance, as long as each of the duplicate address belongs to a different traffic domain.
- **Use of Duplicate entities on the Citrix ADC appliance**. Traffic domains also allow you to use duplicate Citrix ADC feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.
  Note: Duplicate entities with same name are not supported.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Multitenancy**. Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANS configured on the appliance.

Default Traffic Domain

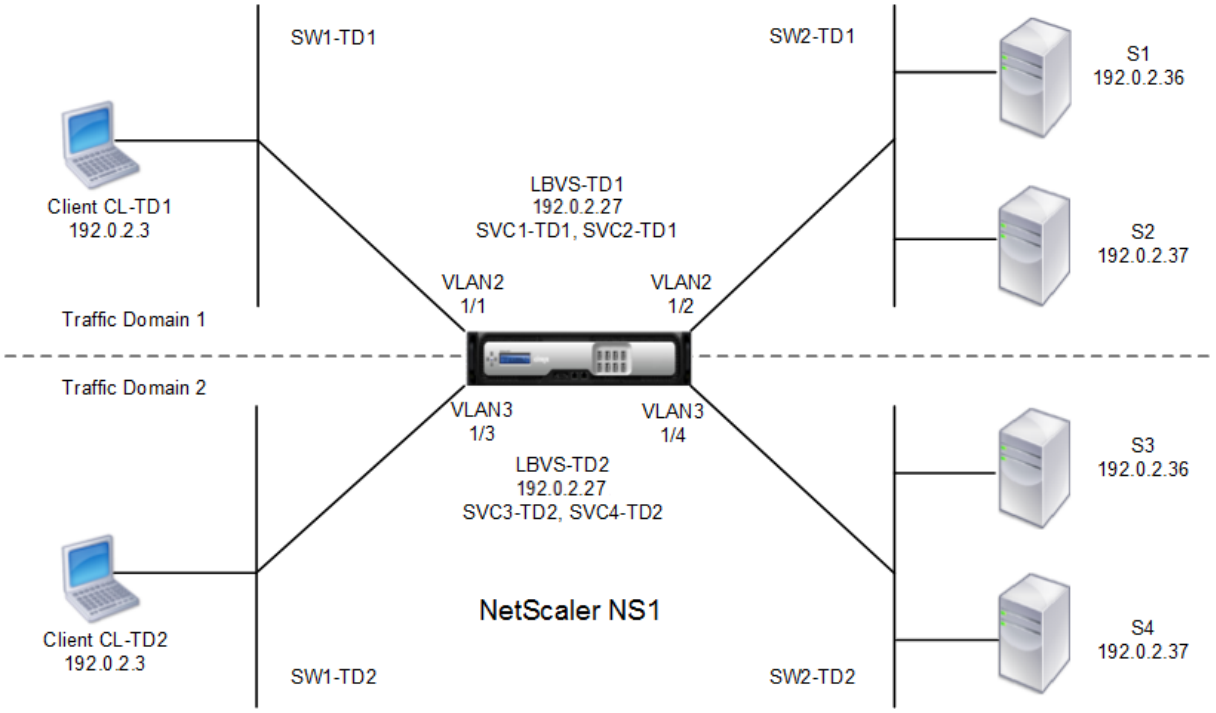
A Citrix ADC appliance has a preconfigured traffic domain, called the *default traffic domain*, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the Citrix ADC appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.

Note: Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see Supported Citrix ADC Features in Traffic Domains.

How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on Citrix ADC appliance NS1.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the Citrix ADC appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.



Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the Citrix ADC appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

On the Citrix ADC appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work

The following table lists the settings used in the example.

Entity	Name	Details
Settings in traffic domain 1		
VLANs bound to traffic domain 1	VLAN 2	VLAN Id: 2 Interfaces bound: 1/1, 1/2
Client connected to TD1	CL-TD1 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD1	LBVS-TD1	IP address: 192.0.2.27
Service bound to virtual server LBVS-TD1	SVC1-TD1	IP address: 192.0.2.36
Service bound to virtual server LBVS-TD1	SVC2-TD1	IP address: 192.0.2.37

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Entity	Name	Details
SNIP	SNIP-TD1 (for reference purposes only)	IP address: 192.0.2.27
Settings in traffic domain 2		
VLAN bound to traffic domain 2	VLAN 3	VLAN Id: 3 Interfaces bound: 1/3, 1/4
Client connected to TD2	CL-TD2 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD2	LBVS-TD2	IP address: 192.0.2.27
Service bound to virtual server LBVS-TD2	SVC3-TD2	IP address: 192.0.2.36
Service bound to virtual server LBVS-TD2	SVC4-TD2	IP address: 192.0.2.37
SNIP in TD2	SNIP-TD2 (for reference purposes only)	IP address: 192.0.2.29

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.27 through L2 switch SW1-TD1.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.27. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.27.
4. NS1 sends an ARP response with the MAC address of interface 1/1.
5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 192.0.2.27. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.
8. S2 replies to SNIP 192.0.2.27 on NS1.
9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.27 through L2 switch SW1-TD2.
2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.
3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.27. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.27. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.
4. NS1 sends an ARP response with the MAC address of interface 1/3.
5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.
6. Client CL-TD2 sends a request to 192.0.2.27. The request is received by LBVS-TD2 on interface 1/3 of NS1.
7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.
8. S2 replies to SNIP 192.0.2.29 on NS1.
9. NS1 sends S2's reply to client CL-TD2.

Supported Citrix ADC Features in Traffic Domains

The Citrix ADC features in the following list are supported in all traffic domains.

> **Important**
>
> Any Citrix ADC feature not listed below is supported only in the default traffic domain.

- ARP table
- ND6 table
- Bridge table
- All types of IPv4 and IPv6 addresses
- IPv4 and IPv6 routes
- ACL and ACL6
- PBR & PBR6
- INAT
- RNAT
- RNAT6
- MSR
- MSR6
- Net profiles

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- SNMP MIBs
- Fragmentation
- Monitors (Scriptable monitors are not supported)
- Content Switching
- Cache Redirection
- Persistency (Persistency groups are not supported)
- Service (Domain based services are not supported)
- Service group (Domain based service groups are not supported)
- Policies (*)
- PING
- TRACEROUTE
- PMTU
- High Availability (connection mirroring is not supported)
- Cluster (Supported on L2 clusters. Not supported on L3 clusters)
- Cookie Persistency
- MSS
- Logging (Syslog is not supported)
- Priority Queuing
- Surge Protection
- HTTP DOSP (**)
- Load balancing (The following types are not supported:)
  - TFTP
  - RTSP
  - Diameter
  - SIP
  - SMPP
- NAT46
- NAT64
- DNS64
- Forwarding Session Rules
- SNMP

> **Note**
>
> - * Policies do not have global binding points for traffic domains. However, policies can be bound to a specific load balancing virtual server of a traffic domain.
> - ** HTTP DOSP policies do not have global binding points for traffic domains. However, HTTP DOSP policies can be bound to a specific load balancing service of a traffic domain.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> - Global Server Loading Balancing (GSLB) and ADNS features in Citrix ADC are not aware of Traffic Domains. If the GSLB configuration needs to be shared across all traffic domains then GSLB methods Static Proximity and Round Trip Time (RTT) do not work. As a workaround in this scenario you can use GSLB methods other than RTT and Static Proximity. For more information, see http://support.citrix.com/article/CTX202277.

Configuring Traffic Domains

Configuring a traffic domain on the Citrix ADC appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
- **Create feature entities on the traffic domain**. Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a *traffic domain identifier* (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the figure titled How Traffic Domains Work.

The CLI has two commands for these two tasks, but the GUI combines them in a single dialog box.

CLI procedures

To create a VLAN and bind interfaces to it by using the CLI:

At the command prompt, type:

- **add vlan** <id>
- **bind vlan** <id> -**ifnum** <slot/port>
- **show vlan** <id>

To create a traffic domain entity and bind VLANs to it by using the CLI:

At the command prompt, type:

- **add ns trafficdomain** <td>

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **bind ns trafficdomain** <td> -**vlan** <id>
- **show ns trafficdomain** <td>

To create a service by using the CLI:

At the command prompt, type:

- **add service** <name> <IP> <serviceType> <port> -**td** <id>
- **show service** <name>

To create a load balancing virtual server and bind services to it by using the CLI:

At the command prompt, type:

- **add lb vserver** <name> <serviceType> <IPAddress> <port> -**td** <id>
- **bind lb vserver** <name> <serviceName>
- **show lb vserver** <name>

GUI procedures

To create a VLAN by using the GUI:

Navigate to **System** > **Network** > **VLANs**, click **Add**, and set the parameters.

To create a traffic domain entity by using the GUI:

Navigate to **System** > **Network** > **Traffic Domains**, click **Add**, and in the **Create Traffic Domain** dialog box, set the parameters.

To create a service by using the GUI:

Navigate to **Traffic Management** > **Load Balancing** > **Services**, click **Add**, and set the parameters.

To create a load balancing virtual server by using the GUI:

Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, click **Add**, and set the parameters.

Inter Traffic Domain Entity Bindings

September 14, 2021

You can bind services in one traffic domain to a virtual server in another traffic domain. All the services to be bound to a virtual server in a different traffic domain must reside in the same traffic domain.

You configure this support by using the existing bind lb vserver command or the related GUI procedure.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

This capability can facilitate interaction between different traffic domains. In an enterprise, servers can be grouped in different traffic domains. Virtual servers are created in a traffic domain that faces the internet. A virtual server from this traffic domain can be configured to load balance servers in another traffic domain. This virtual server receives connection requests from the Internet to be forwarded to the bound servers.

When a Citrix ADC is used in a cloud infrastructure, each tenant can be assigned a separate traffic domain, and all the resources (including servers) for a tenant can be grouped together in the tenant's traffic domain. For each tenant, a virtual server is created for load balancing servers in its traffic domain. All of these virtual servers are grouped together in a single traffic domain that faces the Internet.

Consider an example of in which cloud service provider Example-Cloud-A has three traffic domains, with IDs 10, 20, and 30, configured on Citrix ADC appliance NS1.

Example-Org-A and Example-Org-B are tenants of Example-Cloud-A. Tenant A is assigned traffic domain 20, and tenant B is assigned domain 30. Servers S1 and S2 reside in traffic domain 20 and servers S3 and S4 reside in traffic domain 30.

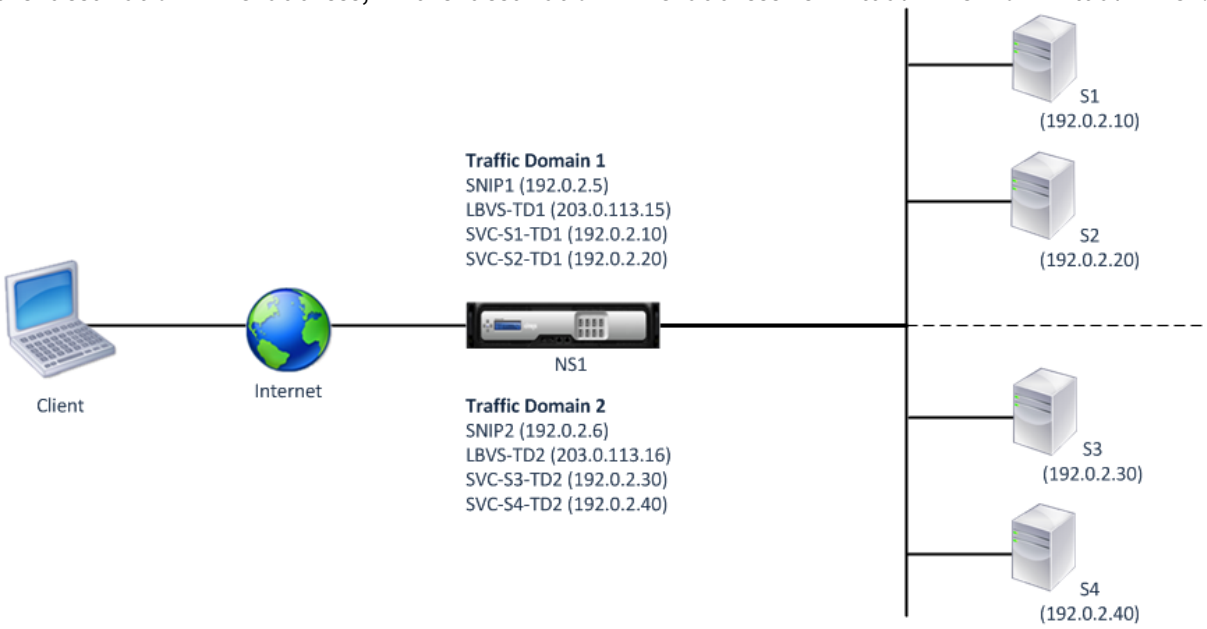
Traffic domain 10 faces the internet. Virtual servers LBVS-1 and LBVS-2 are created in traffic domain 10. LBVS-1, in traffic domain 10, is configured to load balance servers S1 and S2, which are in traffic domain 20. LBVS-2, in traffic domain 10, is configured to load balance servers S3 and S4, which are in traffic domain 30.

Therefore, these virtual servers accept Internet connection requests for servers that are in a different traffic domain than that of the virtual servers.

virtual MAC Based Traffic Domains

September 14, 2021

You can associate a traffic domain with a virtual MAC address instead of with VLANs. The Citrix ADC then sends the traffic domain's virtual MAC address in all responses to ARP queries for network entities in that domain. As a result, the ADC can segregate subsequent incoming traffic for different traffic domains on the basis of the destination MAC address, because the destination MAC address is the virtual MAC address of a traffic domain. After creating entities on a traffic domain, you can easily manage and monitor them by performing traffic domain level operations.



Consider an example in which two traffic domains, with IDs 1 and 2, are configured on Citrix ADC appliance NS1. The Citrix ADC creates a virtual MAC address virtual MAC1 and associates it with traffic domain 1. Similarly, the Citrix ADC created another virtual MAC address virtual MAC2 and associates with traffic domain 2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the Citrix ADC appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. A subnet IP address (SNIP) SNIP1 is configured for enabling the Citrix ADC to communicate with S1 and S2. Because virtual MAC1 is associated with traffic domain 1, the appliance sends virtual MAC1 as the MAC address in all ARP announcements and ARP responses for LBVS-TD1 and SNIP1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the Citrix ADC appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. A SNIP address SNIP2 is configured for enabling the Citrix ADC to communicate with S3 and S4. Because virtual MAC2 is associated with traffic domain 2, the appliance sends virtual MAC2 as the MAC address in all ARP announcements and ARP responses for LBVS-TD2 and SNIP2.

The Citrix ADC segregate subsequent incoming traffic for traffic domains 1 or 2 on the basis of the destination MAC address, if the destination MAC address is virtual MAC1 or virtual MAC2.

The following table lists the settings used in the example: Virtual MAC based traffic domain example settings.

Before you Begin

Following are points to consider before you configure virtual MAC based traffic domain:

1. virtual MAC based traffic domains are easiest way to achieve network traffic segregation.
2. Because virtual MAC based traffic domains segregate network traffic based on virtual MAC addresses and not VLANS, you cannot create duplicate IP addresses on different virtual MAC based traffic domains on a Citrix ADC.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. virtual MAC based traffic domains do not work when the Citrix ADC is deployed only in L2 Mode.
4. Both VLAN and virtual MAC based traffic domains can coexist on a Citrix ADC. virtual MAC based traffic domains actually runs on all VLANs that are not bound to any VLAN based traffic domain.

Configuration Steps

Configuring a virtual MAC based traffic domain on a Citrix ADC appliance consists of the following tasks:

- Create a traffic domain entity and enable the virtual MAC option. Create a traffic domain entity uniquely identified by an ID, which is an integer value, and then enable the virtual MAC option. After creating the traffic domain entity, the Citrix ADC creates a virtual MAC address and then associates it to the traffic domain entity.
- Create feature entities on the traffic domain. Create the required feature entities in the traffic domain by specifying the traffic domain identifier (td) when configuring these feature entities. Citrix ADC owned network entities created in a virtual MAC based traffic domain are associated with the virtual MAC address, which is associated with the traffic domain. The Citrix ADC then sends the traffic domain's virtual MAC address in ARP announcements and ARP responses for these network entities.

CLI procedures

To create a virtual MAC based traffic domain by using the CLI:

At the command prompt, type:

```
add ns trafficDomain <td> [-vmac ( ENABLED          DISABLED )]
```

-

- show ns trafficdomain <td>

To configure a SNIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP –td <id>
- show ns ip <IPAddress> -td <id>

To create a service by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name> -td <id>

To create a load balancing virtual server and bind services to it by using the CLI:

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>
- bind lb vserver <name> <serviceName>
- show lb vserver <name> -td <id>

Example:

```
> add ns trafficDomain 1 -vmac ENABLED
 Done
> add ns trafficDomain 2 -vmac ENABLED
 Done

> add ns ip 192.0.2.5 255.255.255.0 -type -SNIP -td 1
 Done
> add service  SVC-S1-TD1  192.0.2.10 HTTP 80 -td 1
 Done
> add service  SVC-S2-TD1  192.0.2.20 HTTP 80 -td 1
 Done
> add lb vserver  LBVS-TD1 HTTP   203.0.113.15 80 -td 1
 Done
> bind lb vserver  LBVS-TD1 SVC-S1-TD1
 Done
> bind lb vserver  LBVS-TD1 SVC-S2-TD1
 Done

> add ns ip 192.0.2.6 255.255.255.0 -type -SNIP -td 2
 Done
> add service  SVC-S3-TD2  192.0.2.30 HTTP 80 -td 2
 Done
> add service  SVC-S4-TD2  192.0.2.40 HTTP 80 -td 2
 Done
> add lb vserver  LBVS-TD1 HTTP   203.0.113.16 80 -td 1
 Done
> bind lb vserver  LBVS-TD2 SVC-S3-TD2
 Done
> bind lb vserver  LBVS-TD2 SVC-S3-TD2
 Done
```

GUI procedures

To create a virtual MAC based traffic domain by using the GUI:

1. Navigate to System > Network > Interfaces.
2. In the details pane, click Add.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. On the Create Traffic Domain page, set the following parameters:
    - Traffic Domain ID*
    - Enable Mac
4. Click Create.

To configure a SNIP address by using the GUI:

1. Navigate to System > Network > IPs > IPv4
2. Navigate to Network > IPs > IPv4
3. In the details pane, click Add
4. In the Create IP page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
    - IP Address
    - Netmask
    - IP Type
    - Traffic Domain ID
5. Click Create.

To create a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Basic Settings Page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
    - Service Name
    - Server
    - Protocol
    - Port
    - Traffic Domain ID
4. Click Continue, and click Done.
5. Repeat steps 2-4 to create another service.
6. Click Close.

To create a load balancing virtual server and bind services to it by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, click Add.
3. In the Create Virtual Servers (Load Balancing) dialog box, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
    - Name

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- IP Address
- Protocol
- Port
- Traffic Domain ID

4. Click Continue, on the Service Pane, click >.
5. On the Service page, click Insert, and then select the check box for the services that you want to bind to the virtual server.
6. Click Continue, and click Done.
7. Repeat steps 2-5 to create another virtual server

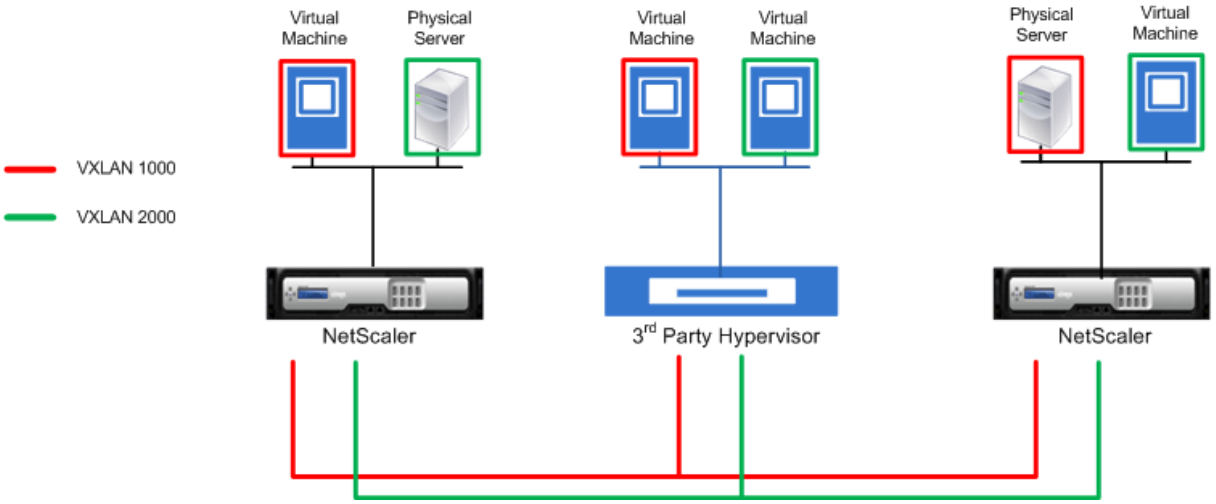
VXLAN

September 14, 2021

Citrix ADC appliances support Virtual eXtensible Local Area Networks (VXLANs). A VXLAN overlays Layer 2 networks onto a layer 3 infrastructure by encapsulating Layer-2 frames in UDP packets. Each overlay network is known as a VXLAN Segment and is identified by a unique 24-bit identifier called the VXLAN Network Identifier (VNI). Only network devices within the same VXLAN can communicate with each other.

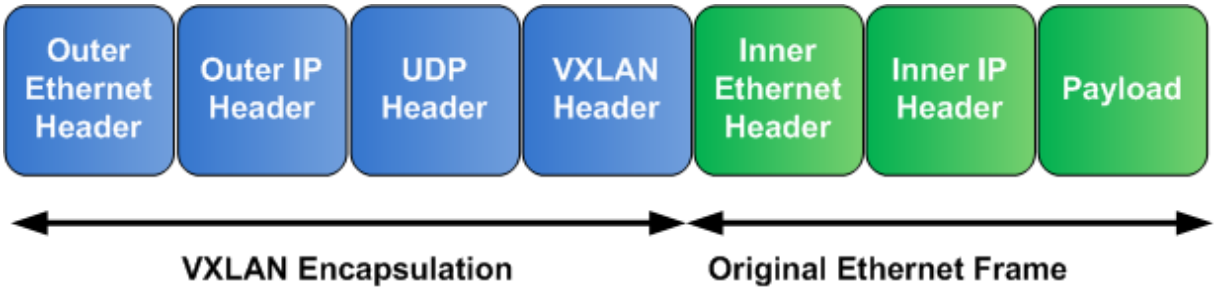
VXLANs provide the same Ethernet Layer 2 network services that VLANs do, but with greater extensibility and flexibility. The two main benefits of using VXLANs are the following:

- **Higher scalability.** Server virtualization and cloud computing architectures have dramatically increased the demand for isolated Layer 2 networks in a datacenter. The VLAN specification uses a 12-bit VLAN ID to identify a Layer 2 network, so you cannot scale beyond 4094 VLANs. That number can be inadequate when the requirement is for thousands of isolated Layer 2 networks. The 24-bit VNI accommodates up to 16 million VXLAN segments in the same administrative domain.
- **Higher flexibility.** Because VXLAN carries Layer 2 data frames over Layer 3 packets, VXLANs extend L2 networks across different parts of a datacenter and across geographically separated datacenters. Applications that are hosted in different parts of a datacenter and in different datacenters but are part of the same VXLAN appear as one contiguous network.



How VXLANs Work

VXLAN Segments are created between VXLAN Tunnel End Points (VTEPs). VTEPs support the VXLAN protocol and perform VXLAN encapsulation and decapsulation. You can think of a VXLAN segment as a tunnel between two VTEPs, where one VTEP encapsulates a Layer2 frame with a UDP header and an



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

IP header and sends it through the tunnel. The other VTEP receives and decapsulates the packet to get the Layer 2 frame. A Citrix ADC is one example of a VTEP. Other examples are third-party hypervisors, VXLAN aware virtual machines, and VXLAN capable switches.

The following illustration displays virtual machines and physical servers connected through VXLAN tunnels.

The following illustration displays the format of a VXLAN packet.

VXLANs on a Citrix ADC use a Layer 2 mechanism for sending broadcast, multicast, and unknown unicast frames. A VXLAN supports the following modes for sending these L2 frames.

- **Unicast mode**: In this mode, you specify the IP addresses of VTEPs while configuring a VXLAN on a Citrix ADC. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to all VTEPs of this VXLAN.
- **Multicast mode**: In this mode, you specify a multicast group IP address while configuring a VXLAN on a Citrix ADC. Citrix ADCs do not support Internet Group Management Protocol (IGMP) protocol. Citrix ADCs rely on the upstream router to join a multicast group, which shares a common multicast group IP address. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN.

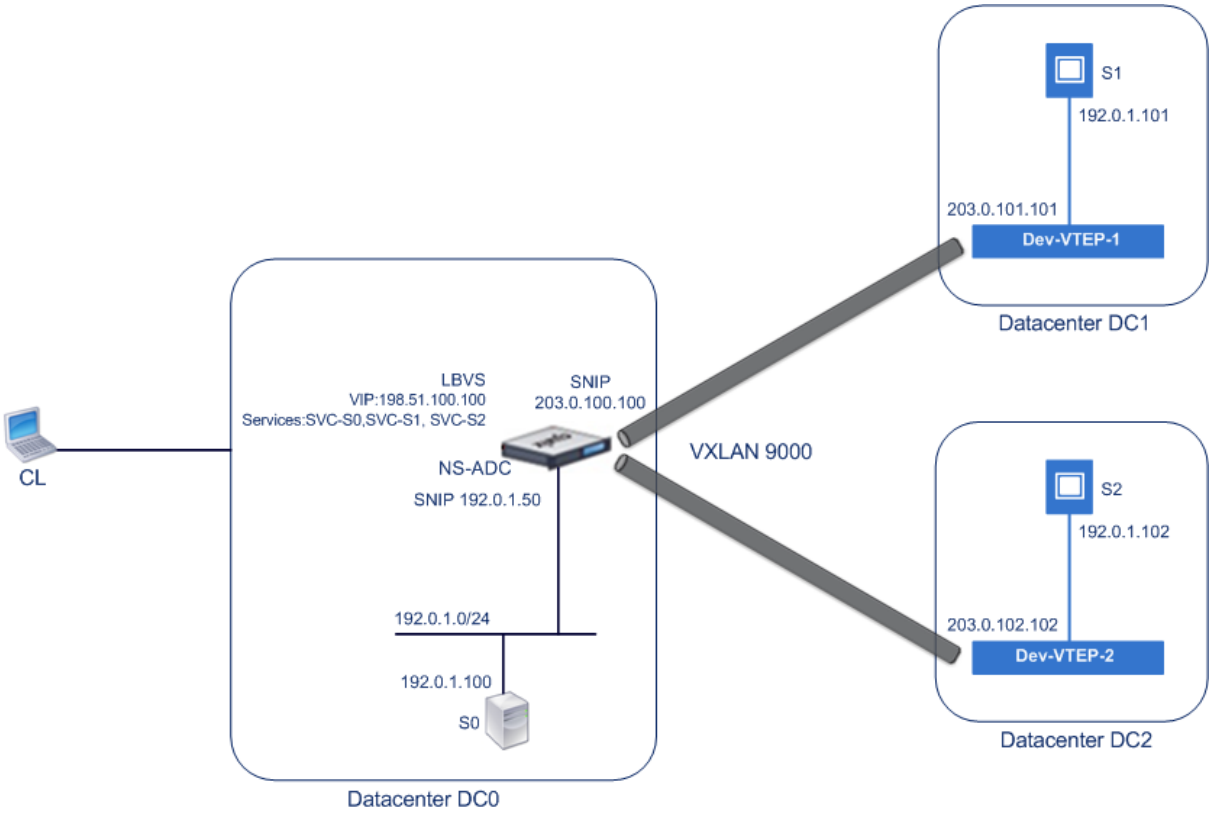
Similar to a Layer 2 bridge table, Citrix ADCs maintain VXLAN mapping tables based on the inner and outer header of the received VXLAN packets. This table maps of remote host MAC addresses to VTEP

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

IP addresses for a particular VXLAN. The Citrix ADC uses the VXLAN mapping table to look up the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the Citrix ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

Because VXLANs function similarly to VLANs, most of the Citrix ADC features that support VLAN as a classification parameter support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.

In a high availability (HA) configuration, the VXLAN configuration is propagated or synchronized to the secondary node.



VXLAN Use Case: Load Balancing across Datacenters

To understand the VXLAN functionality of a Citrix ADC, consider an example in which Example Corp hosts a site at www.example.com. To ensure application availability, the site is hosted on three servers, S0, S1, and S2. A load balancing virtual server, LBVS, on Citrix ADC NS-ADC is used to load balance these servers. S0, S1, and S2 reside in datacenters DC0, DC1, and DC2, respectively. In DC0, server S0 is connected to NS-ADC.

S0 is a physical server, and S1 and S2 are virtual machines (VMs). S1 runs on virtualization host device Dev-VTEP-1 in datacenter DC1, and S2 runs on host device Dev-VTEP-2 in DC2. NS-ADC, Dev-VTEP-1, and Dev-VTEP-2 support the VXLAN protocol.

S0, S1, and S2 are part of the same private subnet, 192.0.1.0/24. S0, S1, and S2 be part of a common broadcast domain, VXLAN 9000 is configured on NS-ADC, Dev-VTEP-1, and Dev-VTEP-2. Servers S1 and S2 are made part of VXLAN9000 on Dev-VTEP-1 and Dev-VTEP-2, respectively.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following table lists the settings used in this example:
VXLAN settings.

Services SVC-S0, SVC-S1, and SVC-S2 on NS-ADC represent S0, S1, and S2. As soon as these services are configured, NS-ADC broadcasts ARP requests for S0, S1, and S2 to resolve IP-to-MAC mapping. These ARP requests are also sent over VXLAN 9000 to Dev-VTEP-1 and Dev-VTEP-2.

Following is the traffic flow for resolving the ARP request for S2:

1. NS-ADC broadcasts an ARP request for S2 to resolve IP-to-MAC mapping. This packet has:
   - Sourced IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
   - Source MAC address = MAC address of the NS-ADC's interface from which the packet is sent out = NS-MAC-1
2. NS-ADC prepares the ARP packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
   - VXLAN header with an ID (VNI) of 9000
   - Standard UDP header, UDP checksum set to 0×0000, and destination port set to 4789.
3. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-1 and Dev-VTEP-2 on VXLAN-9000. The encapsulated packet has:
   - Source IP address = SNIP-VTEP-0 (203.0.100.100).

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the ARP request packet for S2, which is same as in step 1.
5. From the inner and outer header of the VXLAN packet, Dev-VTEP-2 makes an entry in its VXLAN mapping table that shows the mapping of MAC address (NS-MAC-1) and SNIP-VTEP-0 (203.0.100.100) for VXLAN9000.
6. Dev-VTEP-2 sends the ARP packet to S2. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000.
7. S2 responds with its MAC address (MAC-S2). The ARP response packet has:

    - Destination IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
    - Destination MAC address = NS-MAC-1

8. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000. Dev-VTEP-2 encapsulates the ARP response with VXLAN and UDP headers, and sends the resultant packet to SNIP-VTEP-0 (203.0.100.100) of NS-ADC.
9. NS-ADC on receiving the packet, decapsulates the packet by removing the VXLAN and UDP headers. The resultant packet is S2's ARP response. NS-ADC updates it VXLAN mapping table for S2's MAC address (MAC-S2) with Dev-VTEP-2's IP address (203.0.102.102) for VXLAN 9000. NS-ADC also updates it ARP table for S2's IP address (192.0.1.102) with S2's MAC address (MAC-S2).

Following is the traffic flow for load balancing virtual server LBVS in this example:

1. Client CL sends a request packet to LBVS of NS-ADC. The request packet has:

    - Source IP address = IP address of client CL (198.51.100.90)
    - Destination IP address = IP address (VIP) of LBVS = 198.51.110.100

2. LBVS of NS-ADC receives the request packet, and its load balancing algorithm selects server S2 of datacenter DC2.
3. NS-ADC processes the request packet, changing its destination IP address to the IP address of S2 and its source IP address to one of the Subnet IP (SNIP) addresses configured on NS-ADC. The request packet has:

    - Source IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
    - Destination IP address = IP address of S2 (192.0.1.102)

4. NS-ADC finds a VXLAN mapping entry for S2 in its bridge table. This entry indicates that S2 is reachable through Dev-VTEP-2 over VXLAN 9000.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

5. NS-ADC prepares the packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
    - VXLAN header with an ID (VNI) of 9000
    - Standard UDP header, UDP checksum set to 0×0000, and destination port set to 4789.
6. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-2. The request packet has:
    - Source IP address = SNIP address = SNIP-VTEP-0 (203.0.100.100)
    - Destination IP address = IP address of Dev-VTEP-2 (203.0.102.102)
7. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the same packet as in step 3.
8. Dev-VTEP-2 then forwards the packet to S2.
9. S2 processes the request packet and sends the response to the SNIP address of NS-ADC. The response packet has:
    - Source IP address = IP address of S2 (192.0.1.102)
    - Destination IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
10. Dev-VTEP-2 encapsulates the response packet in the same way that NS-ADC encapsulated the request packet in steps 4 and 5. Dev-VTEP-2 then sends the encapsulated UDP packet to SNIP address SNIP-for-Servers (192.0.1.50) of NS-ADC.
11. NS-ADC, upon receiving the encapsulated UDP packet, decapsulates the packet by removing the UDP and VXLAN headers in the same way that Dev-VTEP-2 decapsulated the packet in step 7. The resultant packet is the same response packet as in step 9.
12. NS-ADC then uses the session table for load balancing virtual server LBVS, and forwards the response packet to client CL. The response packet has:
    - Source IP address = IP address of client CL (198.51.100.90)
    - Destination IP address = IP address (VIP) of LBVS (198.51.110.100)

Points to Consider for Configuring VXLANs

Consider the following points before configuring VXLANs on a Citrix ADC:

- A maximum of 2048 VXLANs can be configured on a Citrix ADC.
- VXLANs are not supported in a cluster.
- Link-local IPv6 addresses cannot be configured for each VXLAN.
- Citrix ADCs do not support Internet Group Management Protocol (IGMP) protocol to form a multicast group. Citrix ADCs rely on the IGMP protocol of its upstream router to join a multicast

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

group, which share a common multicast group IP address. You can specify a multicast group IP address while creating VXLAN bridge table entries but the multicast group must be configured on the upstream router. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN. The upstream router then forwards the packet to all the VTEPs that are part of the multicast group.

- VXLAN encapsulation adds an overhead of 50 bytes to each packet:

  Outer Ethernet Header (14) + UDP header (8) + IP header (20) + VXLAN header (8) = 50 bytes

  To avoid fragmentation and performance degradation, you must adjust the MTU settings of all network devices in a VXLAN pathway, including the VXLAN VTEP devices, to handle the 50 bytes of overhead in the VXLAN packets.

  Important: Jumbo frames are not supported on the Citrix ADC VPX virtual appliances, Citrix ADC SDX appliances, and Citrix ADC MPX 15000/17000 appliances. These appliances support an MTU size of only 1500 bytes and cannot be adjusted to handle the 50 bytes overhead of VXLAN packets. VXLAN traffic might be fragmented or suffer performance degradation, if one of these appliances is in the VXLAN pathway or acts as a VXLAN VTEP device.
- On Citrix ADC SDX appliances, VLAN filtering does not work for VXLAN packets.
- You cannot set a MTU value on a VXLAN.
- You cannot bind interfaces to a VXLAN.

Configuration Steps

Configuring a VXLAN on a Citrix ADC appliance consists of the following tasks.

- **Add a VXLAN entity**. Create a VXLAN entity uniquely identified by a positive integer, which is also called the VXLAN Network Identifier (VNI). In this step, you can also specify the destination UDP port of remote VTEP on which the VXLAN protocol is running. By default, the destination UDP port parameter is set to 4789 for the VXLAN entity. This UDP port setting must match the settings on all remote VTEPs for this VXLAN. You can also bind VLANs to this VXLAN. The traffic (which includes broadcasts, multicasts, unknown unicasts) of all bound VLANs are allowed over this VXLAN. If no VLANs are bound to the VXLAN, the Citrix ADC allows traffic of all VLANs, on this VXLAN, that are not part of any other VXLANs.
- **Bind the local VTEP IP address and to the VXLAN entity**. Bind one of the configured SNIP address to the VXLAN to source outgoing VXLAN packets.
- **Add a bridgetable entry**. Add a bridgetable entry specifying the VXLAN ID and the remote VTEP IP address for the VXLAN to be created.
- **(Optional) Bind different feature entities to the configured VXLAN**. VXLANs function similarly to VLANs, most of the Citrix ADC features that support VLAN as a classification parameter

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

also support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.

- **(Optional) Display the VXLAN mapping table**. Display the VXLAN mapping table, which includes mapping entries for remote host MAC address to VTEP IP address for a particular VXLAN. In other words, a VXLAN mapping states that a host is reachable through the VTEP on a particular VXLAN. The Citrix ADC learns VXLAN mappings and updates its mapping table from the VXLAN packets it receives. The Citrix ADC uses the VXLAN mapping table to lookup for the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the Citrix ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

CLI procedures

To add a VXLAN entity by using CLI:

At the command prompt, type

- **add vxlan** <id>
- **show vxlan**<id>

To bind the local VTEP IP address to the VXLAN by using CLI:

At the command prompt, type

- **bind vxlan** <id> -**SrcIP** <IPaddress>
- **show vxlan** <id>

To add a bridgetable by using CLI:

At the command prompt, type

- **add bridgetable** -**mac** <macaddress> -**vxlan** <ID> -**vtep** <IPaddress>
- **show bridgetable**

To display the VXLAN forwarding table by using the command line:

At the command prompt, type:

- **show bridgetable**

GUI procedures

To add a VXLAN entity and bind a local VTEP IP address by using the GUI:

Navigate to **System** > **Network** > **VXLANs**, and add a new VXLAN entity or modify an existing VXLAN entity.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To add a bridgetable by using the GUI:

Navigate to **System** > **Network** > **Bridge Table**, set the following paramters while adding or modifying a VXLAN bridge table entry:

- MAC
- VTEP
- VXLAN ID

To display the VXLAN forwarding table by using the GUI:

Navigate to **System** > **Network** > **Bridge Table**.

```
Example
> add vxlan 9000
Done
> bind vxlan 9000 -srcIP 203.0.100.100

Done
> add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
   203.0.101.101

Done
> add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
   203.0.102.102

Done
```

Support of IPv6 Dynamic Routing Protocols on VXLANs

The Citrix ADC appliance supports IPv6 dynamic routing protocols for VXLANs. You can configure various IPv6 Dynamic Routing protocols (for example, OSPFv3, RIPng, BGP) on VXLANs from the VTYSH command line. An option IPv6 Dynamic Routing Protocol has been added to VXLAN command set for enabling or disabling IPv6 dynamic routing protocols on a VXLAN. After enabling IPv6 dynamic routing protocols on a VXLAN, processes related to the IPv6 dynamic routing protocols are required to be started on the VXLAN by using the VTYSH command line.

To enable IPv6 Dynamic routing protocols on a VXLAN by using the CLI:

- **add vxlan** <ID> [-**ipv6DynamicRouting** (**ENABLED** | **DISABLED**)]
- **show vxlan**

```
In the following sample configuration, VXLAN-9000 is created and has
   IPv6 dynamic routing protocols enabled on it. Then, using the VTYSH
   command line, process for the IPv6 OSPF protocol is started on the
   VXLAN.

> add vxlan 9000 -ipv6DynamicRouting ENABLED
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
4
5  Done
6  > bind vxlan 9000 -srcIP 203.0.100.100
7
8  Done
9  > add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
       203.0.101.101
10
11 Done
12 > VTYSH
13 NS# configure terminal
14 NS(config)# ns IPv6-routing
15 NS(config)# interface VXLAN-9000
16 NS(config-if)# ipv6 router OSPF area 3
```

Extending VLANs from Multiple Enterprises to a Cloud using VXLAN-VLAN Maps

CloudBridge Connector tunnels is used to extend an enterprise's VLAN to a cloud. VLANs extended from multiple enterprises can have overlapping VLAN IDs. You can isolate each enterprise's VLANs, by mapping them to a unique VXLAN in the cloud. On a Citrix ADC appliance, which is the CloudBridge connector endpoint in the cloud, you can configure a VXLAN-VLAN map that links an enterprise's VLANs to a unique VXLAN in the cloud. VXLANs support VLAN tagging for extending multiple VLANs of an enterprise from CloudBridge Connector to the same VXLAN.

Perform the following tasks for extending VLANs of multiple enterprises to a cloud:

1. Create a VXLAN-VLAN map.
2. Bind the VXLAN-VLAN map to a network bridge based or PBR based CloudBridge Connector tunnel configuration on the Citrix ADC appliance on cloud.
3. (Optional) Enable VLAN tagging in a VXLAN configuration.

CLI procedures

To add a VXLAN-VLAN map by using the CLI:

- **add vxlanVlanMap** <name>
- **show vxlanVlanMap** <name>

To bind a VXLAN and VLANS to a VXLAN-VLAN map by using the CLI:

- **bind vxlanVlanMap** <name> [-**vxlan** <positive_integer> -**vlan** <int[-int]> …]
- **show vxlanVlanMap** <name>

To bind a VXLAN-VLAN map to a network bridge based CloudBridge Connector tunnel by using the CLI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

At the command prompt, type one of the following sets of commands.

if adding a new network bridge:

- **add netbridge** <name> [-**vxlanVlanMap** <string>]
- **show netbridge** <name>

if reconfiguring an existing network bridge:

- **set netbridge** <name> [-**vxlanVlanMap** <string>]
- **show netbridge** <name>

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new PBR:

- **add pbr** <name> **ALLOW** (-**ipTunnel** <ipTunnelName> [-**vxlanVlanMap** <name>])
- **show pbr** <name>

if reconfiguring an existing PBR:

- **set pbr** <name> **ALLOW** (-**ipTunnel** <ipTunnelName> [-**vxlanVlanMap** <name>])
- **show pbr** <name>

To include VLAN tags in packets related to a VXLAN by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new VXLAN:

- **add vxlan** <vnid> -**vlanTag** (**ENABLED** | **DISABLED**)
- **show vxlan** <vnid>

if reconfiguring an existing VXLAN:

- **set vxlan** <vnid> -**vlanTag** (**ENABLED** | **DISABLED**)
- **show vxlan** <vnid>

GUI procedures

To add a VXLAN-VLAN map by using the GUI:

Navigate to **System** > **Network** > **VXLAN VLAN Map**, add a VXLAN VLAN map.

To bind a VXLAN-VLAN map to a netbridge based CloudBridge Connector tunnel by using the GUI:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Navigate to **System** > **CloudBridge Connector** > **Network Bridge**, select a VXLAN-VLAN map from the **VXLAN VLAN** drop down list while adding a new network bridge, or reconfiguring an existing network bridge.

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by by using the GUI:

Navigate to **System** > **Network** > **PBRs**, on the Policy Based Routing (PBRs) tab, select a **VXLAN-VLAN** map from the **VXLAN VLAN** drop down list while adding a new PBR, or reconfiguring an existing PBR.

To include VLAN tags in packets related to a VXLAN by using the GUI:

Navigate to **System** > **Network** > **VXLANs**, enable **Inner VLAN Tagging** while adding a new VXLAN, or reconfiguring an existing VXLAN.

```
> add vxlanVlanMap VXLANVLAN-DC1

Done

> bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3000 -vlan 3

Done

> bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3500 -vlan 4

Done

>add vxlanVlanMap VXLANVLAN-DC2

Done

> bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 8000 -vlan 3 4

Done

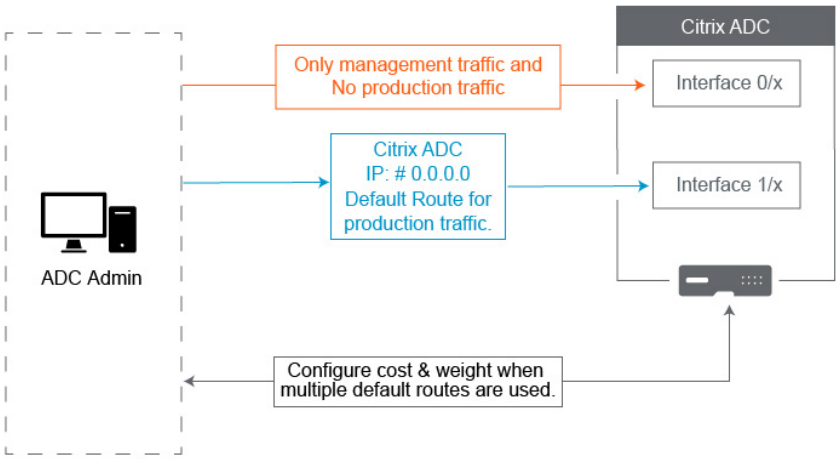
> set pbr PBR-CBC-DC-1-CLOUD ALLOW  -ipTunnel  CBC-DC-1-CLOUD -
   vxlanVlanMap VXLANVLAN-DC1

Done

> set pbr PBR-CBC-DC-2-CLOUD ALLOW  -ipTunnel  CBC-DC-2-CLOUD -
   vxlanVlanMap VXLANVLAN-DC2

Done
```

Best practices for network configurations



August 16, 2023

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following sections talk about some best practices for configuring networking features on a Citrix ADC appliance.

Routing and Default Routes

The following are some best practices for configuring Layer 3 features on a Citrix ADC appliance.

- **Interface `0/x` on a Citrix ADC appliance or Citrix SDX appliance must not be used for production traffic**. On an MPX or SDX, Interfaces named `0/x` are referred to the Management Interfaces. This does not mean you must use these interfaces for Management. What it means is that these interfaces are NOT designed for Production traffic. They do not have the hardware buffers and optimization necessary to achieve sustained 1 Gbps throughput. Therefore, If your Default Route is in the same Subnet as your NSIP, you must either change the default route or use a `1/x` interface for your Management network as the `1/x` interfaces are fully optimized for production 1 Gbps traffic.

  > **Note**:
  >
  > This does not apply to a Citrix ADC VPX appliance.

  - **Option 1**. Do not connect to Interfaces `0/x` –Disconnect the cable from interface `0/1`. NetScaler listens for the NSIP on the other interfaces. (NOTE: This is not an option for SDX, as the SVM and XenServer can only speak to `0/x` interfaces)
  - **Option 2**. change the default route to a different interface as detailed in the next section.

- **Default gateway (route 0.0.0.0) should be on a Production network, and not on any `0/x` interface**. When first setting up a NetScaler, it asks you for the NSIP, Subnet Mask, and Gateway address. The problem this creates for Administrators is that they just configured their default route to be on their Management Network using Interface 0/1.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- To check what your routes are, run in CLI `show route` and your default gateway is the IP in the line where the Network and Netmask are 0.0.0.0. Here's an example where the Gateway is on Line 1:

```
1  > sh route
2          Network          Netmask          Gateway/OwnedIP
              State   Traffic Domain  Type
3          -------          -------          ---------------
              -----   --------------  ----
4  1)      0.0.0.0          0.0.0.0          10.25.213.65     UP
            0               STATIC
5  2)      127.0.0.0        255.0.0.0        127.0.0.1        UP
            0               PERMANENT
6  3)      10.25.213.64     255.255.255.192  10.25.213.68     UP
            0               DIRECT
7  4)      172.16.0.0       255.255.255.0    172.16.0.1       UP
            0               DIRECT
```

- To check the Interface and VLAN used for your Default Gateway, check the ARP table using `sh arp` in CLI. You can also search for the specific IP using `show arp | grep 10.25.213.65`. Here's an example where you see the Gateway 10.25.213.65 is using Interface 1/1 and VLAN 1:

```
1  > sh arp
2          IP               MAC                Iface VLAN
              Origin     TTL     Traffic Domain
3          --               ---                -----  ----
              ------     ---     --------------
4  1)      127.0.0.1        02:00:18:a4:00:1e  LO/1   1
      PERMANENT  N/A    0
5  2)      10.25.213.70     02:00:0f:46:00:28  1/1    1
      DYNAMIC    967    0
6  3)      10.25.213.68     02:00:18:a4:00:1e  LO/1   1
      PERMANENT  N/A    0
7  4)      10.25.213.67     02:00:0f:46:00:28  1/1    1
      DYNAMIC    641    0
8  5)      10.25.213.65     00:08:e3:ff:fd:90  1/1    1
      DYNAMIC    483    0
```

- Change the default route to use a Gateway on your Production Subnet and Interface. Assume your Management network is 10.0.0.0/24 with gateway 10.0.0.1, and Production network is 10.1.1.0/24 with gateway 10.1.1.1. Set up your config like this:

  * SNIP: (Management Access Disabled) 10.1.1.2
  * NSIP: (Management Access Enabled) 10.0.0.2
  * Default Route: 0.0.0.0 0.0.0.0 10.1.1.1 (System > Network > Routes). This uses a router on the SNIP network instead of the NSIP network.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note**:
>
> Changing the default gateway might break management traffic unless you configure static routes, a Policy Based Route, or enable MAC Based Forwarding.

Interfaces, channels, and VLANs

The following are some best practices for configuring Layer 2 features on a Citrix ADC appliance.

- **Do not connect multiple interfaces/channels to the same VLAN, including VLAN 1**:
  - If you do not properly configure your VLANs, it can cause some unexpected packet routing in your network and Layer 2 looping anytime there are more than one Active interface with the same VLAN (either Native or Tagged).
  - By Default, all Interfaces and Channels are on Native VLAN 1. This creates two possible problems:
    * The NetScaler thinks all traffic received is on the same network, so it uses any interface to send the traffic out on. If you have a different Native VLAN on the interface it sent data out on, then the traffic will not be routed as you expect.
    * If the NetScaler receives broadcast packets on one port, it may retransmit on another port. If both switchports are on the same VLAN, you just created a Layer 2 loop.
  - To remove an interface/channel from VLAN 1:
    * If you are not using Native VLANs on your switch interface/port channel. Change the Native VLAN on the NetScaler Interface/Channel to an unused VLAN number such as 999. You should not use the same unused VLAN number for multiple Channels or Interfaces, as it creates a layer 2 loop.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

    * If you are using Native VLANs on your switch interface/port channel. Change the Native VLAN on the NetScaler Interface/Channel to match. However take care not to have multiple active Interfaces or Channels on the same VLAN as doing so creates Layer 2 loops.

    * You cannot remove the Native VLAN. Instead, you can change it or set TagAll for the interface or channel. If the switch port isn't configured with an untagged native VLAN, then enable tagall on the interface so High Availability heartbeat packets will be tagged.

  - To view the Native VLAN on an interface, run `sh interface` in CLI. This will also inform you if the interface is using the TAGALL option.

- **Bind an Interface to your VLAN** - The NetScaler, by default, does not attach a new VLAN to an interface. This means the VLAN is not going to be used until you bind it to an interface. When the new VLAN is not bound to an Interface and that VLAN is Tagged, the NetScaler drops all inbound traffic from that VLAN. Also, do not bind the same VLAN to more than one interface.

  - Bind Subnets to your VLANs. The NetScaler does not work like a typical Router. Most Routers attach IPs to Interfaces. On a NetScaler, the IPs float on any Interface unless configured otherwise. Therefore, any Subnet you want to ensure the NetScaler sends over a specific VLAN, especially when the NetScaler is Initiating that traffic, then you must bind a SNIP within that subnet to the VLAN.

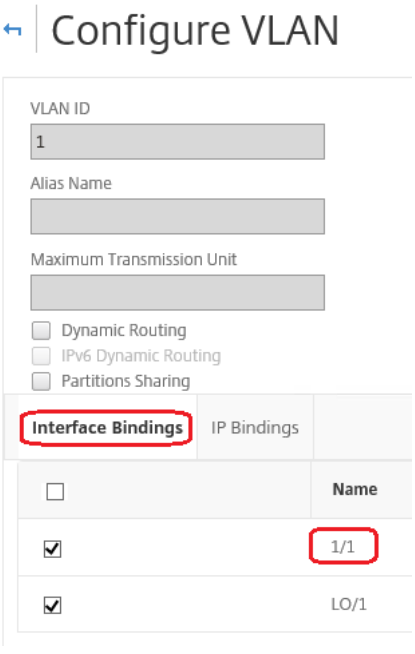
  - A common argument we hear against this is that it used to work fine and now it doesn't without binding the Subnet to the VLAN. This often occurs because the NetScaler learns which VLAN to send traffic out, but this can take time as it builds its ARP tables. After a reboot or firmware upgrade, as it starts building the ARP tables again, it may initially learn and therefore be using a different path than you desire, such as your default route. It's best to instruct it which path to take by Binding the SNIP to the VLAN. Once a SNIP is bound to a VLAN, the entire subnet for that SNIP will be bound to the VLAN.

  - Ensure every SNIP is bound to a VLAN (except in cases where you have more than 1 SNIP in a subnet, then you only must bind one), and that the VLAN, in turn, is bound to only one Interface or channel. It is also often best to have a SNIP in every Subnet, but that is not required as the most specific Route will be used for any destination Subnet that does not have a SNIP.

- To identify the VLAN and Interface used by a Subnet:

  1. Go to **System>Network > VLANs**.
  2. Edit each VLAN configured, in turn, until you find the correct IP address as explained in the next step.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



3. Click the IP Bindings tab to see which IP, and thus which Subnet is bound and thus is using this VLAN.
4. Once you identify the VLAN that has an IP bound to it, where that IP is within the subnet of the Default Route, then click the Interface Bindings. Each Interface or Channel bound to this VLAN will be used.

Example

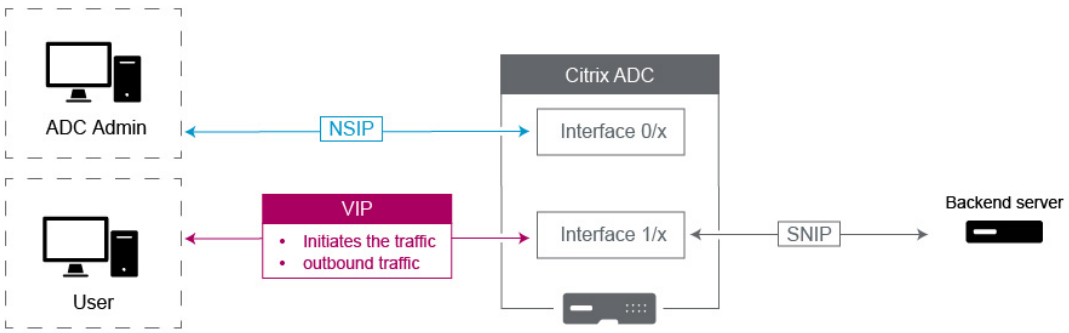
Assume the Default route is `0.0.0.0 0.0.0.0 10.1.1.1`.

Assume you have two SNIPs of 10.0.0.5 and 10.1.1.69. Since 10.1.1.69 is in the subnet of the default route, that is the one you want to look for. In the below screenshots, we are reviewing VLAN 1 and we see the IP 10.1.1.69 is bound to this VLAN, so we know we are looking at the correct VLAN.

Now Click Interface Bindings. In the VLAN Interface bindings we see that Interface 1/1 is used for this subnet, and therefore is used for the default route.

> **NOTE**:
>
> If you do not have any IPs bound to your VLANs, then by default it will be sent out VLAN 1, so in that case look at which Interfaces are bound to VLAN 1. This also means the NetScaler will not use your Configured VLANs for traffic it Initiates unless you bind an IP to the new VLAN.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



Gratuitous ARP

If GARP does not work, use VMAC - By default, the NetScaler uses GARP to advertise its IP to MAC address bindings to other network devices. This typically works without issue, however, as you create more services in the NetScaler, you may begin to experience issues when failing over on an HA pair. The most common issue is that services remain down in the NetScaler you failed over to due to some network devices not having updated their ARP tables with the new MAC address. You can easily verify this by checking their ARP tables to see if the MAC addresses match those on the now-Primary NetScaler. When this occurs, it is highly likely that some of your network devices are limiting the number of GARP advertisements they honor. In this case it is necessary to configure VMAC on all your active interfaces and/or channels. If you expect to have a large configuration on your NetScaler, it may be best to configure VMAC for all interfaces and channels during the initial deployment.

> **NOTE**:
>
> Do not forget to configure VMAC for the Interface or Channel used by your Default Route.

Citrix ADC owned IP Addresses

This section talks about the best practices for configuring Citrix ADC owned IP addresses:

- **Citrix ADC IP (NSIP)**: Generally this IP used for Management because it is the only IP unique to an individual NetScaler in an HA or Cluster environment. Also important to note is that LDAP, RADIUS, and User scripted Monitor traffic (such as the LDAP monitor and StoreFront monitor) will Source from the NSIP and thus route over the VLAN and Interface the NSIP is bound to (Default Native VLAN 1). If you need the LDAP and RADIUS traffic to source from the SNIP, then create an LB virtual server for your back end servers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Subnet IP (SNIP)**: This IP address is used to initiate communication to back-end servers and is always going to initiate traffic. That said, it can be the destination for traffic in these cases:
  - It can be used as the Gateway address on other devices when doing Layer 3 routing on the NetScaler.
  - It can, when enabled, accept Management services, such as access to the GUI, SSH, and SNMP.
- **Virtual IP (VIP)**: The VIP is unique in that it will never be used to initiate outbound traffic. It is intended to receive Traffic only. Once it receives traffic, it replies and sends traffic outbound back to the client. In other words, the VIP address does not initiate the outbound traffic.

Note this also means it is notused as the source for communicating with back-end servers used in, for example, an LB virtual server.

Configure Citrix ADC to source FreeBSD data traffic from a SNIP address

December 9, 2024

Some Citrix ADC data features run on the underlying FreeBSD OS instead of on the Citrix ADC OS. Because of this reason, these features send traffic sourced from the Citrix ADC IP (NSIP) address instead of sourced from a SNIP address. Sourcing the data traffic from the NSIP address is not desirable if your setup has configurations to separate all management and data traffic.

Some of the Citrix ADC data features that run on the underlying FreeBSD OS and send traffic sourced from the NetScaler IP (NSIP) address are:

- Load balancing scriptable monitors
- GSLB autosync

To resolve this issue, you can use the global Layer-2 parameter: `useNetprofileBSDtraffic`. When you enable this parameter, the Citrix ADC features send traffic sourced from one of the SNIP addresses in a net profile associated with the feature.

Before you begin

Before configuring Citrix ADC to source Citrix ADC features-related traffic from a SNIP address, note the following points:

- Currently, the global Layer-2 parameter `useNetprofileBSDtraffic` is supported only for load balancing scriptable monitors.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For configuring Citrix ADC to source GSLB autosync traffic from a SNIP address, you can use extended ACL rules and RNAT rules as a workaround.

- The `useNetprofileBSDtraffic` support for load balancing scriptable monitors is applicable only for net profiles bound to the related services. The `useNetprofileBSDtraffic` support is not applicable for net profiles bound to the related service groups.

  In other words, Citrix ADC does not use any SNIP address from the net profiles bound to the service groups for sourcing load balancing scriptable monitors traffic.

- The `useNetprofileBSDtraffic` support is not applicable for SSL services.

  In other words, Citrix ADC does not use any SNIP address from the net profiles bound to the SSL services for sourcing load balancing scriptable monitors traffic.

Configure Citrix ADC to source scriptable monitors traffic from a SNIP address

- Enable the global Layer-2 parameter `useNetprofileBSDtraffic`.
- Create a net profile and bind at least one SNIP address to it.
- Bind the net profile to the load balancing services.

To enable the Layer-2 parameter useNetprofileBSDtraffic by using the CLI:

At the command prompt, type:

- `set l2param -useNetprofileBSDtraffic (ENABLED / DISABLED)`
- `show l2param`

To Create a net profile and bind SNIP addresses to it by using the CLI:

At the command prompt, type:

- `add netProfile <name> -srcIP <string>`
- `show netProfile`

To bind a net profile to a load balancing service by using the CLI:

At the command prompt, type:

- `set service <name> -netProfile <string>`
- `show service <name>`

Sample configuration

The following sample configuration enables Citrix ADC to source scriptable monitors traffic from a SNIP address. A net profile NETPROFILE-1 is configured with SNIP address 198.51.100.20 bound to

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

it. A user/scriptable monitor USER-MONITOR-1 is created and is bound to a load balancing service SERVICE-1. NETPROFILE-1 is bound to SERVICE-1. Citrix ADC sources all scriptable monitors packets of USER-MONITOR-1 from SNIP address 198.51.100.20.

```
set l2param -useNetprofileBSDtraffic ENABLED

add netprofile NETPROFILE-1 -srcip 198.51.100.20

add lb monitor USER-MONITOR-1 USER -scriptName nsftp.pl -scriptArgs "
    file=Index.png;user=nsroot;password=nsroot" -dispatcherIP 127.0.0.1
    -dispatcherPort 3013 -destIP 203.0.113.90 -destPort 21

bind service SERVICE-1 -monitorName USER-MONITOR-1

set service SERVICE-1 -netProfile NETPROFILE-1
```

Configure Citrix ADC to source GSLB autosync and other FreeBSD originated traffic from a SNIP address

- **Create an extended ACL rule**. An extended ACL rule identifies the GSLB autosync packets. This identification is based on the source IP and destination IP addresses.
- **Apply ACLs**. Applying ACLs activates the newly created ACL rule.
- **Create an ACL based RNAT rule**. An RNAT rule changes the source IP address of these packets from the NSIP address to a SNIP address.

> **Note:**
>
> In a high availability or cluster setup, you must add ACL and RNAT rules for all the NSIP addresses of the setup.

To create an extended ACL by using the CLI:

At the command prompt, type:

- `add acl <aclname> ALLOW -srcIP = <NSIP address> -destIP = <destination IP address of the packets>`
- `show acl <aclName>`

To apply extended ACLs by using the CLI:

At the command prompt, type:

- `apply acls`

To create an ACL based RNAT rule by using the CLI:

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- `add rnat <name> <aclname>`
- `bind rnat <name> -natIP <SNIP address - source IP address for the packets>`
- `show rnat <name>`

Sample configuration

The following sample configuration enables Citrix ADC to source GSLB autosync traffic from a SNIP address. ACL-2 identifies GSLB autosync packets, which are sourced from NSIP address 192.0.1.20 and destined to GSLB site IP address 203.0.113.20. RNAT-2 changes the source IP address to SNIP address 198.51.100.20 for these identified packets.

```
1 add acl ACL-2 ALLOW -srcIP = 192.0.1.20  -destIP = 203.0.113.20
2
3 apply acls
4
5 add rnat RNAT-2 ACL-2
6
7 bind rnat RNAT-2 -natIP 198.51.100.20
```

In general, any FreeBSD originated traffic can use the earlier mentioned ACL with RNAT to choose a specific SNIP as a source IP instead of NSIP. It is good to know the destination IP address.

Priority Load Balancing

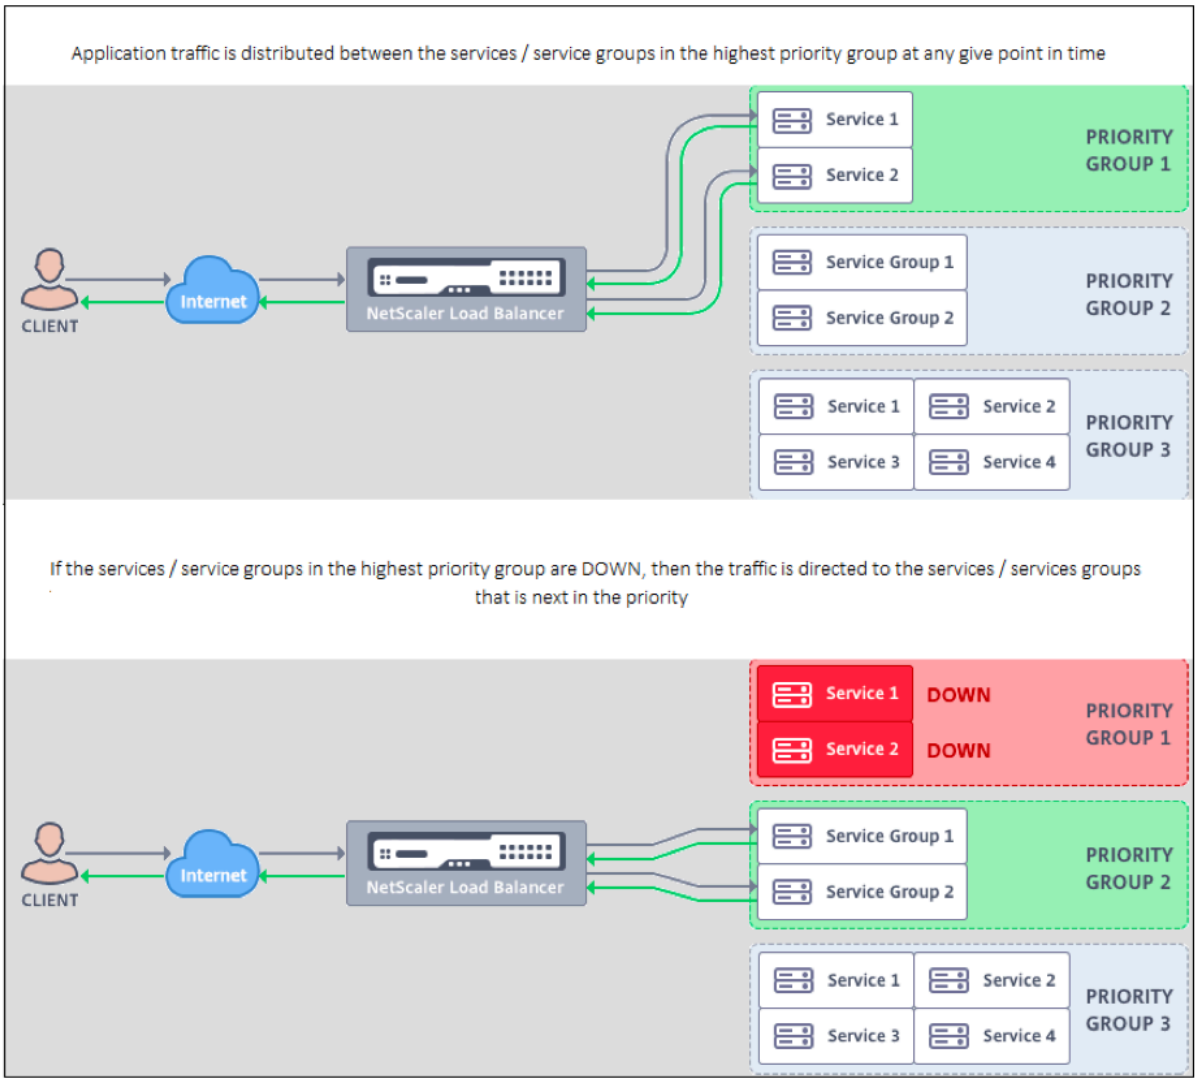
September 14, 2021

The priority load balancing feature enables you to assign a priority number for each of the services or service groups that are bound to a priority load balancing virtual server. A service or a service group with the lowest number has the highest priority. The application traffic is distributed only to this service or a service group as long as this service or the service group is UP. The service or the service group that is assigned the next priority number becomes operational only when all the services or members in the service group with the highest priority are DOWN. However, when any of the services or a member in the service group with the highest priority becomes available again, the traffic is redirected to that service or the service group.

For example, consider the service groups SVG1, SVG2, and SVG3 that is bound to a priority load balancing virtual server. The maximum number of priority groups is set to three. You assign the priority for each group as follows:

- SVG1 –priority 1
- SVG2 –priority 2

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



- SVG3 –priority 3

In this scenario, the application traffic is directed to service group SVG1 because this group is assigned the lowest priority number. If all the members in SVG1 are DOWN, the traffic is distributed to service group SVG2 as this group is assigned the next lower priority number. If all the members in SVG2 are also DOWN, the traffic is distributed to SVG3. However, when any of the members in SVG1 is UP, the traffic is redirected to SVG1 because SVG1 is assigned the lowest number and has the highest priority.

You can assign a priority to a service or a service group to upgrade the specific service or service group that has the highest priority, whenever required with minimal or no impact to the production traffic.

Also, if the upgrade is not successful, you can safely switch to the service or the service group that is next in the priority, with minimal or no impact to the production traffic.

The following figure illustrates the priority load balancing feature.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure priority load balancing

> **Note**
>
> The Citrix ADC priority load balancing configuration is supported only through the GUI. You cannot configure priority load balancing by using the CLI.

1. Navigate to **Traffic Management** > **Priority Load Balancing**> **Virtual *Servers** and specify the protocol for the virtual server, the IP address, and the port number of the virtual server.
2. In the **Maximum Priority Groups** box, enter the number of priority services or the service groups that can be bound to this virtual server. Default value is 2, and the maximum priority that can be set is 10. This parameter is noneditable after it is configured.

   Note:

   After you specify the maximum number of priority groups and click **OK**, a content switching virtual server and "n"number of backup load balancing virtual servers are created. The alphabet "n"represents the maximum number of priority groups.

   For example, if you have entered the virtual server name as vs1, and have set the maximum priority group as 5, then a content switching virtual server with the name `_Pri.LB#vs1#MaxPri=5` and the following 5 load balancing virtual servers are created.

   - `_Pri.LB#vs1#MaxPri=5_LB1`
   - `_Pri.LB#vs1#MaxPri=5_LB2`
   - `_Pri.LB#vs1#MaxPri=5_LB3`
   - `_Pri.LB#vs1#MaxPri=5_LB4`
   - `_Pri.LB#vs1#MaxPri=5_LB5`

3. After you specify the maximum number of priority groups and click **OK**, you are prompted to choose the services or service groups that must be bound to this content switching virtual server.

   - To bind services to the virtual server, click **Insert** in the Services section. Next, either select an existing service or create a service and set the priority for this service. Also, set the priority number at which this service must be bound.
   - To bind service groups to the virtual server, click **Insert** in the Service Groups section. Next, either select an existing service group or create a service group and set the priority for this service group. Also, set the priority number at which this service group must be bound.

   Repeat step 3, depending on the maximum number of priority groups that you have entered.

   Note:

   - The service or the service group with the highest priority is bound to the load balancing virtual server that represents the highest priority.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For example, if you have assigned priority 1 and 2 to service groups SG_App1 and SG_App2 respectively, then SG_App1 is bound to virtual server _Pri.LB#vs1#MaxPri=5_LB1 and SG_App2 is bound to virtual server _Pri.LB#vs1#MaxPri=5_LB2 created in step 2.

- To change the priority of the service group or service, click the edit icon in the Priority Load Balancing Virtual Server page and change the priority as required.
- You cannot set the load balancing methods and persistence for each virtual server explicitly, because the configuration of all load balancing virtual servers is identical.

4. From the Advanced Setting sections, complete the other configuration that meets your requirement.

> **Important:**
>
> The entities created during the priority load balancing configuration must not be modified from other tabs in the GUI and also from the CLI. It is recommended that you modify the priority load balancing entities from the Priority Load Balancing tab only.

Citrix ADC Extensions

September 14, 2021

Citrix ADC extensions can be used to customize a Citrix ADC appliance by writing extension code. Presently, policy extensions and protocol extensions are supported. Policy extensions can be used to extend the policy language. Protocol extensions can be used to add support for custom protocols on a Citrix ADC appliance.

Citrix ADC extensions are also supported on Citrix ADC CPX.

This document includes the following information:

- Citrix ADC Extensions - Language Overview
- Citrix ADC Extensions - Library Reference
- Citrix ADC Extensions API Reference
- Protocol Extensions
- Policy Extensions

Citrix ADC extensions - language overview

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The extension language is based on the Lua 5.2 programming language. Lua provides a compact execution engine with good performance that is designed for embedding in C programs, like Citrix ADC software.

The extension language is dynamically typed, which means each object carries its own type information. Any variable can hold any type at any time during execution, so variable types are not declared.

The language is also free form, where white space between tokens is ignored. Statements may be separated by semicolons, but that is not required and usually not done. Blocks of statements are typically terminated by end. There are no brackets around blocks like the { and } in C or Java.

Identifiers are sequences of letters (a through z and A through Z), digits (0 through 9), and underscores (_), not starting in a digit. Identifiers are case-sensitive, so var, VAR, and Var are all different identifiers.

Comments are started by –. Everything after –is ignored to the end of the line. Example:

```
-- This is a comment.
```

Simple types

September 14, 2021

The language allows values of the following simple types:

- Numbers
- Strings
- Boolean
- Nil
- Other Types

Numbers

All numbers (even integers) are represented by IEEE 754 floating point values. Integers up to 2^54 have exact representations. Numeric values can be represented by:

- Signed and unsigned decimal integers (examples: 10, -5)
- Real numbers with decimal points (10.5, 3.14159)
- Real numbers with exponents (1.0e+10)
- Hexadecimals (0xffff0000)

Citrix ADC policy expressions have three numeric types:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- 32-bit integers (num_at)
- 64-bit integers (unsigned_long_at)
- 64-bit floating point (double_at)

All of these are converted into the number type when passed into an extension function, and numbers are converted to the expected policy numeric type when returned.

Strings

Strings are byte sequences of any length. They correspond to the policy **text_at** type. Strings can contain null (0x00) bytes. Arbitrary binary data can be held in strings, including any character code representation (e.g. UTF-8 and full Unicode). However, string functions **likestring.upper()** assume 8-bit ASCII.

Strings are automatically allocated when used. There is no need (or even way) to explicitly allocate buffers for strings. Strings are also automatically deallocated by garbage collection when no longer in use. There is no need (or even way) to explicitly free strings. This automatic allocation and deallocation avoids some common problems in languages like C, such as memory leaks and dangling pointers.

String literals are character strings enclosed in double or single quotes. There is no difference between the two types of quotes: "a string literal"is the same as 'a string literal'. The usual backslash escaping is available: \s (bell), \b (backspace), \f (form feed), \n (newline/line feed), \t (horizontal tab), \\ (backslash), \"(double quote), and \'(single quote). Decimal byte values can be entered by a backslash and one to three digits (\d, \dd, \ddd). Hexadecimal byte values can be entered by a backslash, an x, and two hex digits (\xhh)

A special syntax call the long bracket notation can be used for long, multi-line string literals. This notation encloses the string in double square brackets with zero or more equal signs between the brackets –the idea is to come up with a combination of brackets and equals that is not in the string. No escape sequences are honored in the string. Some examples:

[[This is a multi-line string using long bracket notation.]]

[=[This is a multi-line string using long notation with [[and]] and and an unescaped in it.]=]

Long bracket notation can be used to make a multi-line comment. Example:

–[[
This is a multi-line comment.
–]]

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Boolean

The usual true and false boolean values are provided. Note that boolean values are different than number values, in contrast to C where zero is assumed to be false and any non-zero value is true.

Nil

nil is a special value that means "no value". It is its own type and is not equivalent to any other value, in contrast to C where NULL is defined to be zero.

Other types

There are two other types, userdata and threads. These are advanced topics and are not covered here.

Variables

September 14, 2021

Variables hold values that may change during extension execution. Because of dynamic typing, any variable may hold values of any type. There are no type declarations for variables. Instead, a variable's type is determined at run time. In fact, the type of a variable's value may change during execution, although this is not a recommended practice. A variable initially has the value nil.

Variable names are identifiers, so are strings of letters, digits, and underscores not beginning in a digit. Examples: headers, combined_headers.

Global variables

In Lua, variables that are not otherwise declared are global within the program. However, global variables are not allowed in policy extension functions, because there are multiple Packet Engines in which a function can be executed, and each Packet Engine has its own memory.

If you use a global variable in your extension, you will get a runtime error: attempt to update or create a global reported in **/var/log/ns.log**.

Typos in variable names are a potential problem, because the variable with the typo will be interpreted as another, global variable, and will not cause a syntax error as in language like C or Java. As noted above, you will get a runtime error instead.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Local variables

A variable may be declared to be local to a block of statements, such as a function. This is done by local variable-name. The variable will be scoped to the block, that is, it will only exist within the block. The local declaration may optionally assign a value to the variable.

Examples:

```
local headers = {}
local combined_headers = {}
```

Expressions

September 14, 2021

Expressions compute values from variable and literal values.

- Arithmetic Operations
- Relational Operations
- Logical Operations
- Concatenation
- Length
- Precedence

Arithmetic operations

Arithmetic operations are performed on number values. If a string value is used in an arithmetic operation, it is converted to a number –if that fails, an error is returned.

a + b	add a and b
a - b	subtract b from a
a * b	multiply a and b
a / b	divide a by b
a % b	modulo = a - math.floor(a/b)*b
a ^ b	raise a to the b power; b can be any number
-a	negate a

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Relational operations

Relational operations compare two values and return true if the relation is satisfied and false if it is not. Relational operations can be performed between values of any type. If the values are not the same type, false is returned. Numbers are compared in the usual way. Strings are compared using the collating sequence for the current locale.

a == b	a is equal to b
a ~= b	a is not equal to b
a < b	a is less than b
a > b	a is greater than b
a <= b	a is less than or equal to b
a >= b	a is greater than or equal to b

Logical operations

Logical operations are traditionally performed on Boolean values, but in this language they can be performed on any two values. nil and false is considered false and any other value is considered true. Logical operations use short-cut evaluation, where if the first value determines the result of the operation, the second value is not evaluated.

a and b	if a is false or nil then return a else return b
a or b	if a is not false and not nil then return a else return b
not a	if a is not false or nil return false else return true

The and and or operations can be used for conditional evaluation within an expression:

a or b	can be used to provide a default value b if a is uninitialized (nil). This is useful for optional parameters in functions.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

a and b or c	can be used to chose non-nil b or c based on the condition a. If a is true, then a and b returns b, and b or c returns b. If a is false, then a and b returns false and false or c returns c. This is equivalent to a ? b : c in the C programming language.

Concatenation

String concatenation is s1 .. s2. This creates a new string large enough to hold the contents of s1 and s2 and copies the contents to the new string. An error results if s1 or s2 are not strings. Note that repeated concatenation may have considerable copying overhead. If you build a string of n bytes by concatenating one byte at a time, this will copy n*(n+1)/2 bytes. For better performance, you can put pieces of a string to be concatenated into a table (discussed later) and then use the table.concat()function. An example of this is shown in the COMBINE_HEADERS() example.

Length

The length of a string s is returned by #s. The # operator is also used with array tables, as discussed later.

Precedence

Operator precedence determines the order in which operations are performed in an expression, with higher precedence operations done before those with lower precedence. Precedence order can as usual be overridden by parentheses. For example, in `a + b \* c`, * has higher precedence than +, so the expression is evaluated as `a + (b \* c)`.

highest
- not # - (unary)
- • / %
- ..
- = ~= < > <= >=

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

-	and
lowest	or

Operations with the same precedence are performed left to right (left associative), except ^ and .. that are performed right to left (right associative). So a^b^c is evaluated as a^(b^c).

Assignment

September 14, 2021

The assignment statement evaluates an expression and assigns the resulting value to a variable.

```
variable = expression
```

As noted earlier, values of any type can be assigned to any variable, so the following is allowed:

```
local v1 = "a string literal"
v1 = 10
```

An assignment statement can actually set multiple variables, using the form

variable1, variable2, …= expression1, expression2, …

If there are more variables than expressions, the extra variables are assigned nil. If there are more expressions than variables, the extra expression values are discarded. The expressions are all evaluated before the assignments, so this can be used to succinctly exchange the values of two variables:

v1, v2 = v2, v1

is equivalent to

tmp = v1
v2 = v1
v1 = tmp

Tables

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Tables are collections of entries with keys and values. They are the only aggregate data structure provided. All other data structures (arrays, lists, sets, and so on) are built from tables. Table keys and values can be any type, including other tables. Keys and values within the same table can mix types.

- Table Constructors
- Table Usage
- Tables as Arrays
- Tables as Records

Table constructors

Table constructors allow you to specify a table with keys and associated values. The syntax is:

{[key1] = value1, [key2] = value2, …}

where the keys and values are expressions. If the keys are strings that are not reserved words, the brackets and quotes around the keys can be omitted. Example:

{key1 = “value1”, key2 = “value2”, key3 = “value3”}

An empty table is specified simply by {}.

A table constructor may be used in an assignment to set a variable to refer to a table. Examples:

local t1 = {} –set t1 to an empty table
local t2 = {key1 = “value1”, key2 = “value2”, key3 = “value3”}

Note that tables themselves are anonymous. More than one variable may refer to the same table. Continuing the above example:

local t3 = t2 –both t2 and t3 refer to the same table

Table usage

As you would expect, you can use keys to find values in a table. The syntax is table[key], where table is a table reference (typically a variable assigned a table), and key is an expression providing the key. If this is used in an expression and the key exists in the table, this returns the value associated with the key. If the key is not in the table, this returns nil. If this is used as the variable in an assignment, and the key does not exist in the table, it creates a new entry for the key and value. If the key already exists in the table, it replaces the key’s value with the new value. Examples:

local t = {} –sets t to an empty table
t[“k1”] = “v1”–creates an entry for key “k1”and value “v1”
v1 = t[“k1”] –sets v1 to the value for key “k1”= “v1”
t[“k1”] = “new_v1”–sets the value for key “k1”to “new_v1”

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Table as arrays

The traditional array can be implemented using a table with integer keys as indices. An array can have any indices, including negative ones, but the convention is to start arrays at index 1 (not 0 as is the case with languages like C and Java). There is a special purpose table constructor for such arrays:

{value1, value2, value3, …}

Array references are then array[index].

The length operator # returns the number of elements in an array with consecutive indices starting at 1. Example:

local a = {“value1”, “value2”, “value3”}
local length = #a –sets length to the length of array a = 3

Arrays can be sparse, where only the defined elements are allocated. But # cannot be used on a sparse array with non-consecutive indices. Example:

local sparse_array = {} –set up an empty array
sparse_array[1] = “value1”–add an element at index 1
sparse_array[99] = “value99”–add an element at index 99

Multidimensional arrays can be set up as tables of tables. For example, a 3x3 matrix could be set up by:

local m = {{1, 2, 3}, {4, 5, 6}, {7, 8, 9} }
local v22 = m[2][2] –sets v22 to 5

Tables as records

Records with fields can be implemented as tables with field name keys. The reference form table.field can be used for table[“field”]. Examples:

local person = {name = “John Smith”, phone = “777-777-7777”}
local name = person.name –sets name to “John Smith”

An array of tables can be used for a sequence of records. Example:

local people = {
{name = “John Smith”, phone = “777-777-7777”},
{name = “Jane Doe”, phone = “888-888-8888”}
…
}

name = people[2].name –sets name to “Jane Doe”

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Control structures

September 14, 2021

The extension function language provides the usual statements to control program execution.

- If Then Else
- While Do and Repeat Until
- Numeric For
- Break
- Goto

If Then Else

If statements select blocks of statements to execute based on one or more conditions. There are three forms:

If then Form

```
if expression then
     statements to execute if expression is not false or nil
end
```

If then else Form

```
if expression then
     statements to execute if expression is not false or nil
else
     statements to execute if expression is false or nil
end
```

If then elseif else Form

```
if expression1 then
     statements to execute if expression1 is not false or nil
     elseif expression2 then
          statements to execute if expression2 is not false or nil
. . .
else
     statements to execute if all expressions are false or nil
end
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
if headers[name] then

     local next_value_index = #(headers[name]) + 1
     headers[name][next_value_index] = value

else

     headers[name] = {
 name .. ":" .. value }

end
```

Note:

- The expression is not enclosed in parentheses as is the case in C and Java.
- There is no equivalent to the C/Java switch statement. You have to use a series of if elseif statements to do the equivalent.

While Do and Repeat Until

The **while** and **repeat** statements provide loops controlled by an expression.

```
while expression do
     statements to execute while expression is not false or nil
end

repeat

     statements to execute until expression is not false or nil

until expression
```

Example for while:

```
local a = {
 1, 2, 3, 4 }

local sum, i = 0, 1 -- multiple assignment initializing sum and i
while i <= #a do -- check if at the end of the array
     sum = sum + a[i] -- add array element with index i to sum
     i = i + 1 -- move to the next element
end
```

Example for repeat:

```
sum, i = 0, 1 -- multiple assignment initializing sum and i
repeat
     sum = sum + a[i] -- add array element with index i to sum
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
4       i = i + 1 -- move to the next element
5   until i > #a -- check if past the end of the array
```

Of course it is possible to write a loop that does not terminate, for example, if you omit the i = i + 1 statement in either of these examples. When such a function is executed, Citrix ADC will detect that the function did not complete in a reasonable time and will kill it with a runtime error:

```
Cpu limit reached. Terminating extension execution in [[string "
function extension function..."]]: line line-number.
```

will be reported in /var/log/ns.log.

Numeric For

There are two types of for loops. The first is the numeric for, which is similar to the usual use of the for statement in C and Java. The numeric for statement initializes a variable, tests if the variable has passed a final value, and if not executes a block of statements, increments the variable, and repeats. The syntax for the numerical for loop is:

```
1   for variable = initial, final, increment do
2
3       statements in the loop body
4
5   end
```

where initial, final, and increment are all expressions that yield (or can be converted to) numbers. variable is considered to be local to the for loop statement block; it cannot be used outside of the loop. increment can be omitted; the default is 1. The expressions are evaluated once at the beginning of the loop. The terminating condition is variable > final if the increment is positive and variable < final if the increment is negative. The loop terminates immediately if the increment is 0.

Example (equivalent to the while and repeat loops in the preceding section):

```
1   sum = 0
2   for i = 1, #a do -- increment defaults to 1
3       sum = sum + a[i]
4   end
```

The second type of for loop is the generic for, which can be used for more flexible types of loops. It involves the use of functions, so will be discussed later after functions have been introduced.

Break

The break statement is used inside a while, repeat, or for loop. It will terminate the loop and resume execution at the first statement after the loop. Example (also equivalent to the preceding while, repeat, and for loops):

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
sum, i = 0, 1
while true do
     if i > #a then
          break
     end
     sum = sum + a[i]
     i = i + 1
end
```

Goto

The goto statement can be used to jump forward or backward to a label. The label is an identifier, and its syntax is ::label::. The goto statement is goto label. Example (once again equivalent to the preceding loops):

```
sum, i = 0, 1
::start_loop::
     if i > #a then
          goto end_loop -- forward jump
     end
     sum = sum + a[i]
     i = i + 1
     goto start_loop -- backwards jump
::end_loop::
. . .
```

There has been a long running controversy over using gotos in programming. In general, you should try to use the other control structures to make your functions more readable and reliable. But occasional judicious use of gotos may lead to better programs. In particular, gotos may be useful in handling errors.

Functions

September 21, 2021

Functions are a basic building block of programming –they are a convenient and powerful way to group statements that perform a task. They are the interface between the Citrix ADC appliance and extension code. For policies, you define policy extension functions. For protocols, you implement callback functions for the protocol behaviors. Functions consist of function definitions that specify what values are passed into and out of the function and what statements are run for the function, and function calls, which run functions with specific input data and get results from the function.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Protocol behavior callback functions

The TCP client behavior consists of a callback function (on_data) that processes TCP client data stream events. To implement Message Based Load Balancing (MBLB) for a TCP based protocol, you can add code for this callback function to process the TCP data stream from the client and parse the byte stream into protocol messages.

The callback functions in a behavior are called with a context, which is the processing module state. The context is the instance of the processing module. For example, the TCP client behavior callbacks are called with different contexts for different client TCP connections.

In addition to the context, the behavior callbacks can have other arguments. Usually the rest of the arguments are passed as payload, which is the collection of all the arguments. So, the programmable processing module instances can be seen as a combination of instance state plus event callback functions, that is, the context plus behavior. And the traffic flows through the pipeline as event payload.

Prototype of TCP client callback function:

```
1              Function                client on_data (ctxt, payload)
2
3                                              //.code
4
5              end
```

Where,

- ctxt - TCP client processing context
- payload –event payload
  - payload.data - TCP data received, available as a stream of bytes

Policy extension functions

Since the NetScaler policy expression language is typed, the definition of an extension function must specify the types of its inputs and its return value. The **Lua function** definition has been extended to include these types:

‘

function self-type: function-name(parameter1: parameter1-type, and so on): return-type
statements
end

Where,

The types are NSTEXT, NSNUM, NSBOOL, or NSDOUBLE.

‘

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Self-type is the type of the implicit self-parameter that is passed into the function. When the extension function is used in a Citrix ADC policy expression, this is the value generated by the expression to the left of the function. Another way to view this is that the function extends that type in the Citrix ADC policy language.

The parameter-types are the types of each parameter specified in the extension function call in the policy expression. An extension function can have zero or more parameters.

Return-type is the type of the value returned by the extension function call. It is the input to the part of the policy expression, if any, to the right of the function, or else is the value of the expression result.

Example:

```
function NSTEXT:COMBINE_HEADERS(): NSTEXT
```

Use of the extension function in a policy expression:

```
HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\r\n").COMBINE_HEADERS()
```

Here the self-parameter is the result of `HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\r\n")`, which is a text value. The result of the COMBINE_HEADERS() call is text, and since there is nothing to the right of this call, the result of the entire expression is text.

Local function definition

Besides extension functions, no global functions can be defined in an extension file. But local functions can be defined within extension functions using the normal Lua function statement. This declares the name of the function and the names of its parameters (also known as arguments), and like all declarations in Lua, does not specify any types. The syntax for this is:

‘

Local function function-name(parameter1-name, parameter2-name, and so on)
statements
end
‘

The function and parameter names are all identifiers. (The function name is actually a variable and the function statement is shorthand for local function-name = function(parameter1, and so on), but you don’t have to understand this subtlety to use functions.)

Note that and so on is used here for continuation of the pattern of parameter names instead of the usual …. This is because …itself actually means a variable parameter list, which will not be discussed here.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Function body and return

The block of statements between the function and end statements is the function body. In the function body, the function parameters act like local variables, with values supplied by the function calls, as described previously.

The return statement supplies values to be returned to the caller of the function. It must appear at the end of a block (in a function, if then, for loop, and so on; It can be in its own block do return …end). It may specify no, one, or more than one return values:

‘

Return –returns nil
return expression –one return value
return expression1, expression2, …–multiple return values
‘

Examples:

‘

```
local function fsum(a)
local sum = 0
for i = 1, #a do
sum = sum + a[i]
end
return sum
end
```

```
Local function fsum_and_average(a)
local sum = 0
for i = 1, #a do
sum = sum + a[i]
end
return sum, sum/#a
end
```

‘

Function calls

A function call runs the body of a function, supplying values for its parameters, and receiving results. The syntax for a function call is function-name(expression1, expression2, and so on), where the function parameters are set to the corresponding expressions. The number of expressions and parameters need not be the same. If there are fewer expressions than parameters, the remaining parameters are

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

set to nil. So you can make one or more parameters at the end of the call optional, and your function can check if they are specified by checking if they are not nil. A common way to do this is with the or operation:

‘

```
Function f(p1, p2) –p2 is optional
p2 = p2 or 0 –if p2 is nil, set to a default of 0
. . .
end
```

‘

If there are more expressions than parameters, the remaining expression values are ignored.

As noted previously, functions can return multiple values. These returns can be used in a multiple assignment statement. Example:

‘

```
Local my_array = {1, 2, 3, 4}
local my_sum, my_ave = sum_and_average(my_array)
```

‘

Iterator functions and generic for loops

Now that we have introduced functions, we can talk about generic for loops. The syntax for the generic for loop (with one variable) is:

‘

```
For variable in iterator(parameter1, parameter2, and so on) do
statements in the for loop body
end
```

‘

Where iterator() is a function with zero or more parameters that provide a value for variable on each iteration of the loop body. The iterator function keeps track of where it is in the iteration using a technique called closure, which you don’t have to worry about here. It signals the end of the iteration by returning nil. Iterator functions can return more than one value, for use in a multiple assignments.

Writing an iterator function is beyond the scope of this paper, but there are few useful built-in iterators that illustrate the concept. One is the pairs() iterator, which iterates through the entries in a table and returns two values, the key and the value of the next entry.

Example:

‘

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
Local t = {k1 = “v1”, k2 = “v2”, k3 = “v3”}
local a = {} –array to accumulate key-value pairs
local n = 0 –number of key-value pairs
for key, value in pairs(t) do
n = n + 1
a[n] = key.. “= “.. Value –add key-value pair to the array
end
local s = table.concat(a, “;”) –concatenate all key-value pairs into one string
‘
```

Another useful iterator is the string.gmatch() function, which will be used in the following COMBINE_HEADERS() example.

Citrix ADC extensions - library reference

September 14, 2021

The list of libraries supported in policy extensions.

- Basic library
- String library
- Regular Expression Patterns - Character Classes
- Regular Expression Patterns - Pattern Items
- Table library
- Math library
- Bitwise library
- Operating System library
- Citrix ADC library

Basic library

assert(v[,message])	Issues an error, with an optional message, when v is false.
error(message)	Terminates a function and reports the error message.
ipairs(a)	Iterator for an array a. Returns an index and value for each iteration.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

pairs(t)	Iterator for a table t. Returns a key and value for each iteration.
tonumber(e[,base])	Converts e to a number, with an optional base.
tostring(v)	Converts v to a string
type(v)	Returns the type of v: number, string, boolean, table, etc.
getmetatable (object)	Returns nil if the object does not have a metatable. Otherwise, if the object's metatable has a "__metatable"field, returns the associated value. Otherwise, returns the metatable of the given object.
setmetatable (table, metatable)	Sets the metatable for the given table. (You cannot change the metatable of other types from Lua, only from C.) If metatable is nil, removes the metatable of the given table. If the original metatable has a "__metatable"field, raises an error.
select (index, ···)	Returns all arguments after argument number index. If index is string "#", then it returns the total number of extra arguments it received.
pcall (f [, arg1, ···])	Calls function f with the given arguments in protected mode. It returns status code as first result which tells whether call succeeded or not. If call succeeded, then along with status code it also returns all results from the call, otherwise returns error message.
xpcall (f, msgh [, arg1, ···])	This function is similar to pcall, except that it also takes an argument for error handling.
_VERSION	Returns the current interpreter version.

String library

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

string.byte(s[,i[,j]])	Returns the byte values for s[i] to s[j]. Default i = 1 and j = i
string.char(…)	Returns a string constructed of the integer parameters.
string.find(s,pattern[,init[,plain])	Looks for the first match of a regular expression pattern in s. Return the first and last indices of match or nil. init is index to start, default 1. plain = true means pattern is not a regex.
string.format(form,…)	Returns a formatted version of the parameters.
string.gmatch(s,pattern)	Iterator for searching s with the regex pattern. Returns matching values.
string.gsub(s,pattern,repl[,n])	Returns a copy of s in which all (or n) occurences of the pattern have been replaced by repl.
string.len(s)	Returns the string length.
string.lower(s)	Returns a copy of the string converted to lowercase.
string.match(s,pattern[,init])	Looks for the first match of the regex pattern in s and returns the captures or the whole pattern. init is the index to start, default 1.
string.rep(s,n[,sep])	Returns a string that is n copies of s, with separator sep, default no separator
string.reverse(s)	Returns a string that is s reversed.
string.sub(s,i[,j])	Returns the substring of s from s[i] to s[j], default j is the end of the string.
string.upper(s)	Returns a copy of the string converted to uppercase.
string.dump (function)	Returns a string containing a binary representation of the given function.

Regular expression patterns - character classes

x	the character x, except for magic characters ^$()%.[]*+-?)

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

.	any character
%a	any letter
%c	any control character
%d	any digit
%g	any printable character except space
%l	any lowercase letter
%p	any punctuation character
%s	any white space character
%u	any uppercase letter
%w	any alphanumber letter
%x	an escaped magic character x (for example %%)
[set]	a set of characters: sequence of individual characters, ranges x-y, and % classes
[^set]	characters not in the set.

Regular expression patterns - pattern items

X	a character class
X*	0 or more longest repetitions of characters in X
X+	1 or more repetitions of characgers in X
X-	0 or more shortest repetitions of characters in X
X?	0 or 1 character in X
%n	n=1 to 9; matches nth captured string
%bxy	matches substring between two balanced characters x and y. Example %b() matches substring between two balanced parentheses.
%f[set]	matches an empty string at at any position such that the next character belongs to set and the previous character does not belong to set.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

A pattern is a sequence of pattern items. ^pattern matches the beginning of a string and pattern$ matches the end of the string.

Matched substrings can be captured using (pattern). Parentheses with no pattern () capture the current string position (a number).

Table library

table.concat(list[,sep[,i[,j]]])	Returns a string list[i] .. sep .. list[i+1] .. sep . . . list[j]. Default sep is the empty string. Default i is 1, j is #list.
table.insert(list,[pos,]value)	Inserts value into list at index pos. Default for pos is #list (end of the list).
table.pack(…)	Returns an array containing the parameters starting at index 1, and a key n with the total number of parameters.
table.remove(list[,pos])	Removes from list the element at position pos, shifting elements to fill the position. Returns the removed element. Default for posis #list (end of the list.)
table.sort(list[,comp])	Sort the elements of list in place. comp is the comparison function to use. Default for comp is <.
table.unpack(list[,i[,j]])	Returns list[i] through list[j]. Default for i is 1 and j is #list<c/ode>.

Math library

Various trigonometric and logarithmic functions not shown.

math.abs(x)	Returns the absolute value of x.
math.ceil(x)	Returns the smallest integer >= x.
math.floor(x)	Returns the largest integer <= x.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

math.fmod(x,y)	Returns the remainder of x/y rounding the quotient towards zero.
math.huge	A value >= any other number.
math.max(x,…)	Returns the maximum argument.
math.min(x,…)	Returns the minimum argument.
math.modf(x)	Returns the integral and fractional parts of x.
math.random()	Returns a pseudo-random number between 0 and 1.
math.random(m)	Returns a pseudo-random integer between 1 and m.
math.random(m, n)	Returns a pseudo-random integer betwen m and n.
math.randomseed(x)	Sets the pseudo-random number generator set to x.
math.sqrt(x)	Returns the square root of x (x^0.5)
math.acos(x)	Returns the arc cosine of x (in radians).
math.asin(x)	Returns the arc sine of x (in radians).
math.atan(x)	Returns the arc tangent of x (in radians).
math.atan2(y, x)	Returns the arc tangent of y/x (in radians).
math.cos(x)	Returns the cosine of x.
math.cosh(x)	Returns the hyperbolic cosine of x.
math.sin(x)	Returns the sine of x.
math.sinh(x)	Returns the hyperbolic sine of x.
math.tan(x)	Returns the tangent of x.
math.tanh(x)	Returns the hyperbolic tangent of x.
math.deg(x)	Returns the angle x (given in radians) in degrees.
math.exp(x)	Returns the value e^x.
math.frexp (x)	Returns m and e such that x = m2e, e is an integer and the absolute value of m is in the range [0.5, 1).
math.ldexp (m, e)	Returns m2e (e should be an integer).

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

math.log (x [, base])	Returns the logarithm of x in the given base. The default for base is e.
math.pow (x, y)	Returns x^y.
math.rad (x)	Returns the angle x (given in degrees) in radians.
math.pi	The value of π.

Bitwise library

Unless otherwise stated:

- All functions accept numeric arguments in the range (-2^51,+2^51).
- Each argument is normalized to the remainder of its division by 2^32 and truncated to an integer (in some unspecified way), so that its final value falls in the range [0,2^32 - 1].
- All results are in the range [0,2^32 - 1].

bit32.arshift(x,disp)	Returns x arithmetically shifted disp bits to the right (+disp) or left (-disp).
bit32.band(…)	Returns the bitwise and of the arguments.
bit32.bnot(x)	Returns the bitwise negation of x.
bit32.bor(…)	Returns the bitwise or of the arguments.
bit32.btest(…)	Returns true if the bitwise and of the arguments is not zero.
bit32.bxor(…)	Returns the bitwise exclusive or of the arguments.
bit32.extract(n,field[,width])	Returns the bits in n from field to field + width - 1 (bits number from most to least significant). Default for width is 1.
bit32.replace(n,v,field[,width])	Returns a copy of n with bits from field to field + width -1 replaced by v. Default width is 1.
bit32.lrotate(x,disp)	Returns x rotated disp bits to the left (+disp) or right (-disp).
bit32.lshift(x,disp)	Returns x shifted disp bits to the left (+disp) or right (-disp).

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

bit32.rrotate(x,disp)	Returns x rotated disp bits to the right (+disp) or left (-disp).
bit32.rshift(x,disp)	Returns x shifted disp bits to the right (+disp) or left (-disp).

Operating system library

os.clock ()	Returns an approximation of the amount in seconds of CPU time.
os.date ([format [, time]])	Returns a string or a table containing date and time, formatted according to the given string format.
os.time ([table])	Returns the current time when called without arguments, or a time representing the date and time specified by the given table.
os.difftime (t2, t1)	Returns the number of seconds from time t1 to time t2.

Citrix ADC library

ns.logger:level(message)	To log messages where level is emergency, alert, critical, error, warning, notice, info, or debug. The parameters are the same as the C printf() function: a format string, and a variable number of arguments to supply values for the % specifiers in the format string.

Citrix ADC extensions API reference

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Behaviors are a formalization of common programmable patterns that are available on a Citrix ADC appliance. For example, a TCP virtual server supports a TCP client behavior and a TCP server behavior. A behavior is a pre-defined set of callback functions. You can implement behaviors by providing callback functions. For example, a TCP client behavior can consist of the on_data function, which processes the TCP data stream.

TCP client behavior

on_data - function callback for TCP client data events. The callback takes two arguments:

- **ctxt** - TCP client processing context
- **payload** –event payload
  - **payload.data** - TCP data received, available as a stream of bytes

TCP server behavior

on_data - function callback for TCP server data events, the callback takes two arguments:

- **ctxt** - TCP server processing context
- **payload** –event payload
  - **payload.data** - tcp data received, available as a stream of bytes

TCP client context

The context that is passed to the TCP client event callbacks:

- **ctxt.output** - The next processing context in the pipeline. Extension call back handlers can send ns.tcp.stream type data to ctxt.output using the events DATA, which means partial message or EOM which means end of protocol message. The EOM event may or may not have TCP data with it. An EOM event with TCP data can be sent without a preceding DATA event to send a whole protocol message data and mark the end of message. The load balancing decision is made, downstream by the load balancing virtual server, on the first data received. A new load balancing decision is made after the receipt of the EOM message. So, to stream protocol message data, send multiple DATA events with the last event as EOM. All the contiguous DATA events and the following EOM events are sent to the same server connection selected by the load balancing decision on the first DATA event in the sequence.
- **ctxt.input** - The previous processing context in the pipeline where the TCP stream data is coming from.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **ctxt:hold(data)** - Function to store the data for future processing. On calling hold with data, the data is stored in the context. Later, when more data is received on the same context, newly received data is appended to the previously stored data and the combined data stream is then passed to the on_data callback function. After calling a hold, the data reference is no longer usable and gives error on any usage.
- **ctxt.vserver** - The virtual server context.
- **ctxt.client** –Client connection processing context. This processing context can be used to send data to the client, and to fetch some connection related information like IP address, source and destination ports.
- **ctxt:close()** –Close the client connection by sending FIN to the client. After calling this API, the client processing context is no longer usable and gives error on any usage.

TCP server context

The context that is passed to the TCP server event callbacks:

- **ctxt.output** –The next processing context in the pipeline. Extension call back handlers can send ns.tcp.stream type data to ctxt.output using the events DATA, which means partial message or EOM which means end of protocol message.
- **ctxt.input** - The previous processing context in the pipeline where the TCP stream data is coming from.
- **ctxt:hold(data)** - Function to store the data for future processing. On calling hold with data, the data is stored in the context. Later, when more data is received on the same context, newly received data is appended to the previously stored data and the combined data stream is then passed to the on_data callback function. After calling a hold, the data reference is no longer usable and gives error on any usage.
- **ctxt.vserver** - The virtual server context.
- **ctxt.server** - Server connection processing context. This processing context can be used to send data to the server, and to fetch some connection related information like IP address, source and destination ports.
- **ctxt:reuse_server_connection ()** - This API is used to allow the server connection to be reused for other client connections in the server context only. This API can be used only if an EOM event is used (in ns.send() API) to send the data in the client context. Otherwise, the ADC appliance throws an error.

  To allow a server connection to be reused by other clients, this API must be called at the end of each response message. After calling this API, if more data is received on this server connection, this is treated as an error and the server connection is closed. If this API is not used, then the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

server connection can be used only for that client for which it was opened. Also, if the same server is selected for another load balancing decision for that client, then the same server connection is used to send the client data. After using this API, server connection stops being tied to the client connection for which it was opened, and can be reused for a new load balancing decision for any other client connection. After calling this API, the server context is no longer usable and throws an error on any usage.

Note: This API is available in Citrix ADC 12.1 build 49.xx and later.

- **ctxt:close()** –Close the server connection by sending FIN to the server. After calling this API, the client processing context is no longer usable and displays an error on any usage.

  Note: This API is available in Citrix ADC 12.1 build 50.xx and later.

Vserver context

The user virtual server context available through the contexts passed to callbacks:

- **vserver:counter_increment(counter_name)** - Increments the value of a virtual server counter passed as argument. Currently the following built-in counters are supported.
  - **- invalid_messages** –Number of invalid requests/responses on this virtual server.
  - **- invalid_messages_dropped** –Number of invalid requests/responses dropped by this virtual server.
- **vserver.params** - The configured parameters for the user virtual server. Parameters provide configurability of extensions. The extension code can access parameters that are specified in the CLI to add a user virtual server.

Client connection context

Client connection processing context to get connection related information.

- **client.ssl** –SSL context
- **client.tcp** –TCP context
- **client.is_ssl** –True if client connection is SSL-based

Server connection context

Server connection processing context to get connection related information.

- **server.ssl** –SSL context
- **server.tcp** –TCP context
- **server.is_ssl** –True if server connection is SSL-based

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

TCP context

TCP context operates on TCP protocol.

- **tcp.srcport** –Source port as a number
- **tcp.dstport** - Destination port as a number

IP context

IP context works on IP or IPv6 protocol data.

- **ip.src** - Source IP address context.
- **ip.dst** - Destination IP address context.

Note: This API is available in Citrix ADC 12.1 build 51.xx and later.

IP address context

IP address context works on IP or IPv6 address data.

- **<address>.to_s** - The address string in the appropriate ASCII notation.
- **<address>.to_n** - The address'numeric value as a string of bytes in network order (4 bytes for IPv4 and 16 bytes for IPv6).
- **<address>.version** - Returns 4 for IPv4 and 6 for IPv6.
- **<address>:subnet(<prefix value>)** - Returns the subnet address string after applying the prefix number.
  - For IPv4 address, value must be between 0 and 32
  - For IPv6 address, value must be between 0 and 128.
- **<address>:apply_mask(<mask string>)** - Returns the address string after applying mask string. API validates the version of argument and does appropriate error checking.
- **address>:eq(<address string>)** - Returns true or false based on whether the argument is equivalent to the address object. API validates the version of the arguments.

Note: This API is available in Citrix ADC 12.1 build 51.xx and later.

SSL context

The SSL context provides information related to frontend SSL connection.

- **ssl.cert** –SSL certificate context. For the client connection, it provides client certificate context and for the server connection, it provides server certificate context.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **ssl.version** - A number that represents the SSL protocol version of the current transaction, as follows:

  - 0: The transaction is not SSL-based
  - 0x002: The transaction is SSLv2
  - 0x300: The transaction is SSLv3
  - 0x301: The transaction is TLSv1
  - 0x302: The transaction is TLSv1.1
  - 0x303: The transaction is TLSv1.2

- **ssl.cipher_name** - SSL Cipher name as string if invoked from an SSL connection, otherwise gives NULL string.
- **ssl.cipher_bits** –Number of bits in cryptographic key.

SSL certificate context

- **Cert.version** –Version number of the certificate. If the connection is not SSL based, returns 0.
- **Cert.valid_not_before** –Date in string format before which certificate is not valid.
- **Cert.valid_not_after** –Date in string format after which certificate is no longer valid.
- **Cert.days_to_expire** –Number of days before which certificate is valid. Returns -1 for expired certificate.
- **Cert.to_pem** –Certificate in binary format.
- **cert.issuer** - Distinguished Name (DN) of the Issuer in the certificate as a name-value list. An equals sign (“=”) is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs.

  Following is an example of the returned DN:
  /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@n
- **cert.auth_keyid** –Context of Authority Key Identifier extension of the X.509 V3 certificate.

  - **auth_keyid.exists** - TRUE if the certificate contains an Authority Key Identifier extension.
  - **auth_keyid.issuer_name** - Issuer Distinguished Name in the certificate as a name-value list.
    An equals sign (“=”) is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs.

  Following is an example:
  /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@n

  - **auth_keyid.keyid** - KeyIdentifier field of the Authority Key Identifier as a blob

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

  - **auth_keyid.cert_serialnumber** - SerialNumber field of the Authority Key Identifier as a blob.

- **cert.pk_algorithm** - Name of the public key algorithm used by the certificate.
- **cert.pk_size** - Size of the public key used in the certificate.
- **cert.serialnumber** - Serial number of the client certificate. If this is a non-SSL transaction or there is an error in the certificate, this gives an empty string.
- **cert.signature_algorithm** - Name of the cryptographic algorithm used by the CA to sign this certificate.
- **cert.subject_keyid** - Subject KeyID of the client certificate. If there is no Subject KeyID, this gives a zero-length text object.
- **cert.subject** - Distinguished Name of the Subject as a name-value. An equals sign (“=”) separates names and values and a slash (“/”) delimits name-value pairs.

Following is an example:
/C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycom

Citrix ADC libraries

- **ns.tcp.stream** - String like library for handling TCP data as a stream of bytes. The maximum size of TCP stream data on which these APIs can work is 128 KB. The ns.tcp.stream library functions can also be called in the usual extension object oriented style of calling. For example, data:len() is the same as ns.tcp.stream.len(data)

  - **ns.tcp.stream.len(data)** - Returns length of data in bytes, similar to Lua’s string.len
  - **ns.tcp.stream.find(data, pattern [, init])** - Function similar to Lua’s string.find. In addition, it also does partial matching at the end of data. Upon partial match, the start index is returned and the end index becomes nil.
  - **ns.tcp.stream.split(data, length)** - Splits the data into two chunks, the first chunk is of the specified length. After a successful split the original data is no longer usable as a TCP data stream. Any attempt to use it that way causes an error.
  - **ns.tcp.stream.byte(data[, i [, j]])** - Function similar to Lua’s string.byte. Returns the internal numerical codes of the characters data[i], data[i+1], …, data[j].
  - n**s.tcp.stream.sub(data, i [, j])** - Function similar to Lua’s string.sub. Returns the substring of s that starts at i and continues until j.
  - **ns.tcp.stream.match(data, pattern, [, init])** - Function similar to Lua’s string.match. Looks for the first *match* of pattern in string s.

- **ns.send(processing_ctxt, event_name, event_data)** - Generic function to send events to a processing context. Event data is a Lua table that can have any content. The contents depend

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

on the event. After the ns.send() API is called, the data reference is no longer usable. Any attempt to use it causes an error.

- **ns.pipe(src_ctxt, dest_ctxt)** - Using a call to pipe() API, extension code can connect source context to a destination context. After a call to pipe, all the events that are sent from source context to the next module in the pipeline go directly to the destination context. This API is typically used by the module that makes the pipe() call, to remove itself from the pipeline.
- **ns.inet** –Library for internet addresses.
  - **ns.inet.apply_mask(address_str, mask_str)** - returns the address string after applying mask string.
  - **ns.inet.aton(address_str)** - Returns address'numeric value as a string of bytes in network order (4 bytes for IPv4 and 16 for IPv6).
  - **ns.inet.ntoa(byte_str)** - Converts numeric byte value as a string of bytes to address string.
  - **ns.inet.ntohs(number)** - Convert the given network byte order to host byte order. If the input is greater than 2^16 - 1, then throws an error.
  - **ns.inet.htons(number)** - Converts the given host byte order to network byte order. If the input is greater than 2^16 - 1, then throws an error.
  - **ns.inet.ntohl(number)** - Converts the given network byte order to host byte order. If the input is greater than 2^32 - 1, then throws an error.
  - **ns.inet.htonl(number)** - Converts the given host byte order to network byte order. If the input is greater than 2^32 - 1, then throws an error.
  - **ns.inet.subnet(address_str, subnet_value)** –Returns the subnet address string after applying given subnet.

Protocol extensions

September 14, 2021

The Citrix ADC appliances have native support for protocols such as HTTP. In addition to this, you can use protocol extensions to add support for custom protocols. Presently only TCP-based custom protocols are supported, for example, Message Queuing Telemetry Transport (MQTT) protocol. For secure transactions, TCP over SSL is also supported.

The protocol extensions on the Citrix ADC appliance are part of the high-level scripting infrastructure available on the Citrix ADC appliance. The scripting language is based on the Lua 5.2 programming language. To add a custom protocol to a Citrix ADC appliance, the user has to write extension code to implement the applicable behaviors. For example, the ns.tcp.client and ns.tcp.server behaviors are applicable to TCP based protocols. To implement a behavior, implement only the callbacks that you want to customize. If callback is not implemented, its default takes effect. For more information about

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

the scripting language, see Citrix ADC Extensions - Language Overview. For details on behaviors, see Citrix ADC Extensions API Reference.

The Citrix ADC protocol extensions can be used for the following:

- Add new protocol support on the Citrix ADC appliance programmatically, using extensions.
- Parse protocol traffic and do protocol-specific message based load balancing (MBLB).
- Configure user defined load balancing persistence.

Protocol extensions - architecture

September 14, 2021

To achieve traffic-level extensibility, the traffic processing on a Citrix ADC appliance is exposed as a pipeline of separate processing modules. Traffic flows through them as it processes it from ingress to egress. These modules in the pipeline follow a shared nothing model. Message passing is used to send the traffic data from one module in the pipeline to the next module.

Certain points in the traffic processing pipeline are made extensible, so that you can add code to customize the Citrix ADC behavior.

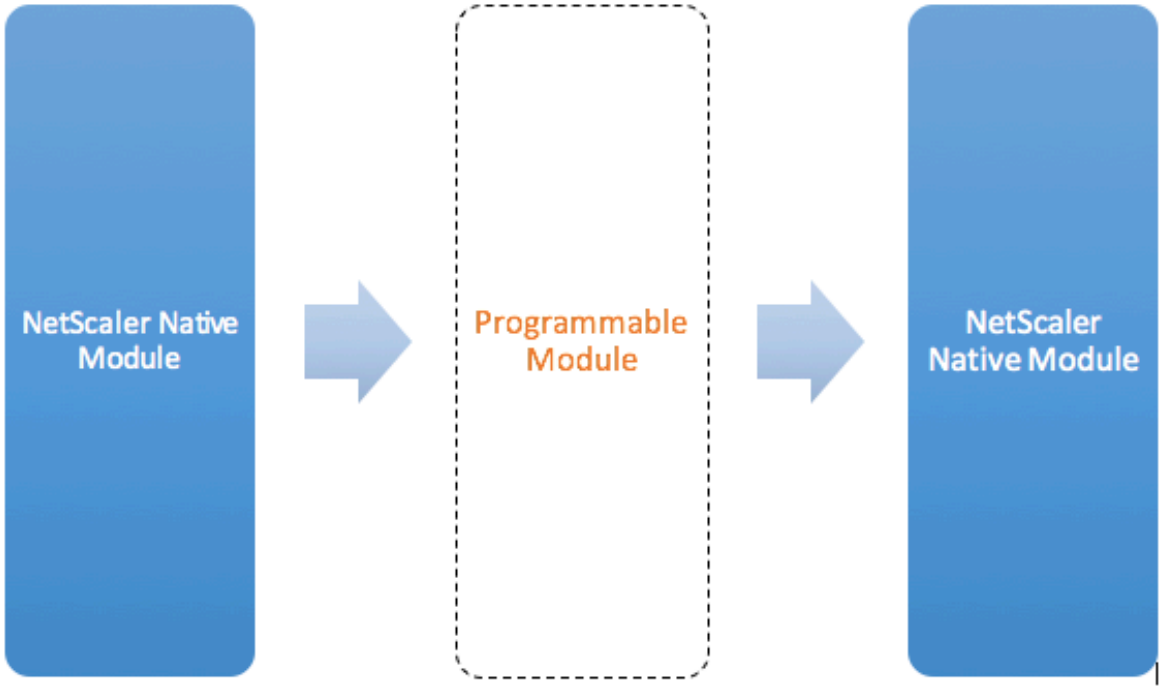


Figure: A Programmable Module In the Traffic Pipeline

By default, the traffic bypasses a programmable module to which you do not add any code.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

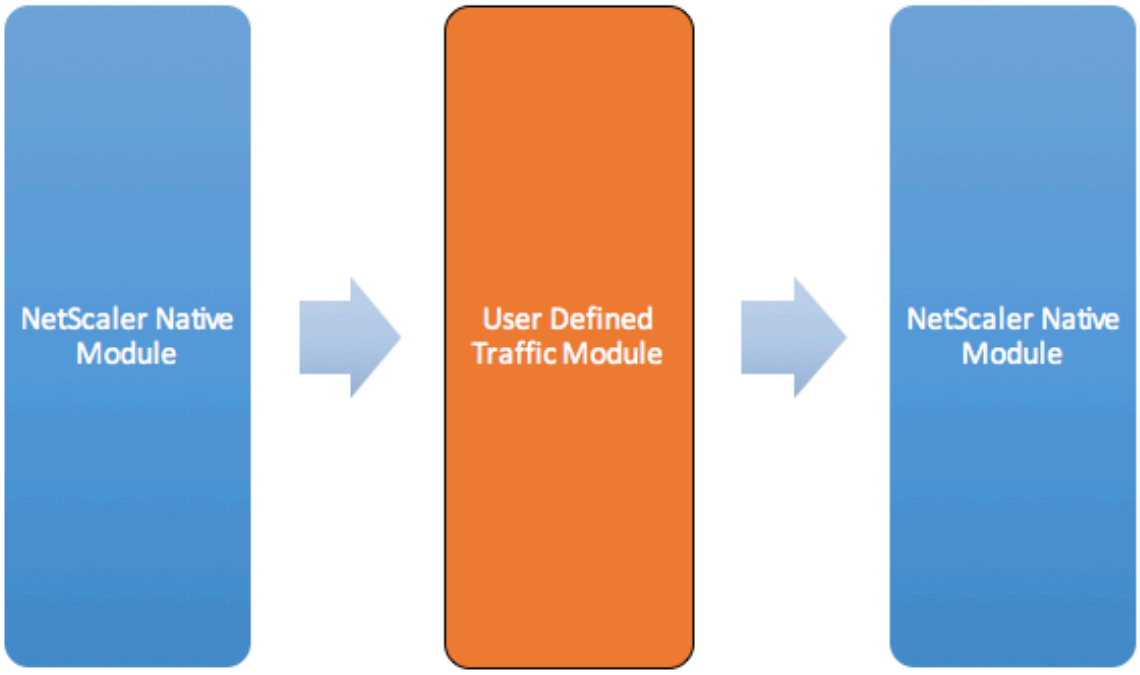

Figure: User Defined Traffic Module

Behaviors

The programmable interfaces for customizing the traffic handling are called behaviors. Behaviors are basically a formalization of common programmable patterns that are available on a Citrix ADC appliance. The behaviors consist of a pre-defined set of event callback functions. You can implement a behavior by providing callback functions conforming to the behavior.

For example, the TCP client behavior consists of a callback function (on_data) that processes TCP client data stream events. To implement Message Based Load Balancing (MBLB) for a TCP based protocol, you can add code for this callback function to process the TCP data stream from the client and parse the byte stream into protocol messages.

Context:

The callback functions in a behavior are called with a context, which is the processing module state. The context is the instance of the processing module. For example, the TCP client behavior callbacks are called with different contexts for different client TCP connections.

Payload:

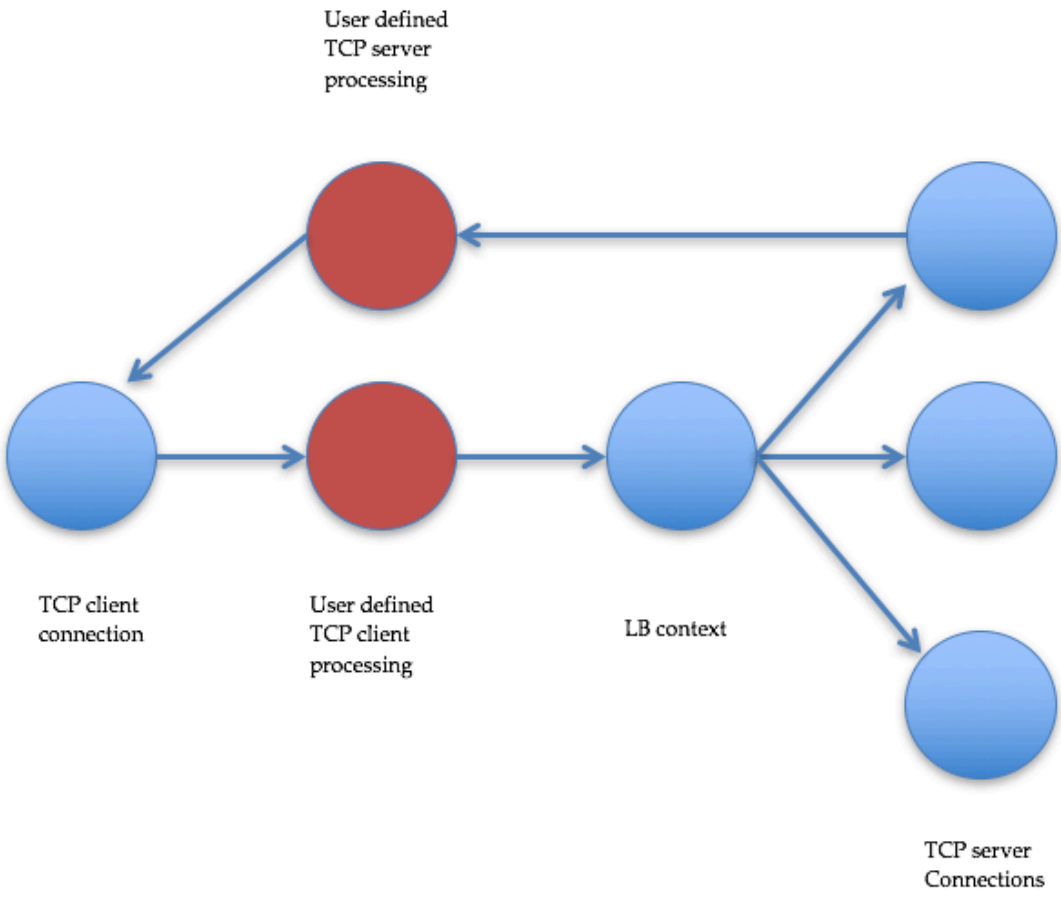
In addition to the context, the behavior callbacks can have other arguments. Usually the rest of the arguments are passed as payload, which is the collection of all the arguments.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

So, the programmable processing module instances can be seen as a combination of instance state plus event callback functions, that is, the context plus behavior. And the traffic flows through the pipeline as event payload.

For Citrix ADC API extensions, see Citrix ADC extension API reference.

The following code snippet shows a user defined function to handle TCP client data stream events. The context and payload are passed to the function by Citrix ADC code. This code simply forwards the TCP data received in every call to the next processing module context in the pipeline. In this case, the next module is the load balancing (LB) context, which is a Citrix ADC native module.



```
function client.on_data(ctxt, payload)
    ns.send(ctxt.output, "DATA", {
 data = payload.data }
 )
end
```

Protocol extensions - traffic pipeline for user defined TCP client and server behaviors

September 14, 2021

The following figure illustrates the sample protocol extension - traffic pipeline for user defined TCP client and server behaviors

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Traffic Pipeline For User Defined TCP Client And Server Behaviors

Add a custom protocol by using protocol extensions

The command line interface (CLI) commands for custom protocol use the keyword "user"to signify the user defined nature of the underlying configuration entities. With the help of extension code, you can add a new user protocol to the system and add user virtual servers for user-defined protocols. The user virtual servers are in turn configurable by setting parameters. Configured values for virtual server parameters are available in the extension code.

The following example illustrates the user flow for adding support for a new protocol. The example adds MQTT protocol support to the system. MQTT is a machine-to-machine "Internet of Things"connectivity protocol. It is a lightweight publish/subscribe messaging transport. Useful for connections with remote locations, this protocol uses client and broker tools to publish messages to subscribers.

1. Import the MQTT protocol extension implementation file to Citrix ADC system. The code listing for mqtt.lua is given below. The example below imports the MQTT extension file hosted on a

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

webserver.

```
import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
```

2. Add a new user TCP based protocol to the system using the extension.

```
add user protocol MQTT -transport TCP -extension mqtt_code
```

3. Add a user load balancing vserver and bind backend services to it.

```
1 add service mqtt_svr1 10.217.24.48 USER_TCP 1501
2 add service mqtt_svr2 10.217.24.48 USER_TCP 1502
3 add lb vserver mqtt_lb USER_TCP  – lbmethod USER_TOKEN
4 bind lb vserver mqtt_lb mqtt_svr1
5 bind lb vserver mqtt_lb mqtt_svr2
```

4. Add a user vserver for the newly added protocol. Set the defaultlb to the LB vserver configured above.

```
add user vserver mqtt_vs MQTT 10.217.24.28 8765 -defaultLb
mqtt_lb
```

5. Optionally, enable MQTT session persistence based on ClientID, set the persistence type to USERSESSION.

```
set lb vserver mqtt_lb -persistenceType USERSESSION
```

Protocol extensions - use cases

September 14, 2021

Protocol extensions can be used for the following use cases.

- Message based load balancing (MBLB)
- Streaming
- Token based load balancing
- Load balancing persistence
- TCP connection based load balancing
- Content based load balancing
- SSL
- Modify traffic
- Originate traffic to client or server
- Process data on the connection establishment

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Message based load balancing

Protocol extensions support Message Based Load Balancing (MBLB), which can parse any protocol on a Citrix ADC appliance and load balance the protocol messages arriving on one client connection, that is, distribute the messages over multiple server connections. MBLB is achieved by user code that parses the client TCP data stream.

The TCP data stream is passed to the on_data callbacks for client and server behaviors. The TCP data stream is available to the extension functions through a Lua string like interface. You can use an API similar to the Lua string API to parse the TCP data stream.

Useful APIs include:

```
data:len()
```

```
data:find()
```

```
data:byte()
```

```
data:sub()
```

```
data:split()
```

Once the TCP data stream has been parsed into a protocol message, the user code achieves load balancing by just sending the protocol message to the next context available from the context passed to the on_data callback for the client.

The ns.send() API is used to send messages to other processing modules. In addition to the destination context, the send API takes the event name and optional payload as arguments. There is one-to-one correspondence between the event name and the callback function names for the behaviors. The callbacks for events are called on_<event_name>. The callback names use only lowercase.

For example, the TCP client and server on_data callbacks are user-defined handlers for events named "DATA."For sending the whole protocol message in one send call, the EOM event is used. EOM, which stands for end of message, signifies the end of protocol message to the LB context down stream, so a new load balancing decision is made for data that follows this message.

The extension code might sometimes not receive the whole protocol message in the on_data event. In such a case, the data can be held by using the ctxt:hold() API. The hold API is available for both TCP-client and server-callback contexts. When "hold with data"is called, the data is stored in the context. When more data is received in the same context, the newly received data is appended to the previously stored data and the on_data callback function is called again with the combined data.

Note: The load balancing method used depends on the configuration of the load balancing virtual server corresponding to the load balancing context.

The following code snippet shows the use of the send API to send the parsed protocol message.

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
    function client.on_data(ctxt, payload)
        --
        -- code to parse payload.data into protocol message comes here
        --
        -- sending the message to lb
        ns.send(ctxt.output, "EOM", {
data = message }
)
    end -- client.on_data

    function server.on_data(ctxt, payload)
        --
        -- code to parse payload.data into protocol message comes here
        --
        -- sending the message to client
        ns.send(ctxt.output, "EOM", {
data = message }
)

    end -- server.on_data
```

Streaming

In some scenarios, holding the TCP data stream until the whole protocol message is collected might not be necessary. In fact, it is not advised unless it is required. Holding the data increases memory usage on Citrix ADC appliance and can make the appliance susceptible to DDoS attacks by exhausting the memory on Citrix ADC appliance with incomplete protocol messages on many connections.

Users can achieve streaming of TCP data in the extension callback handlers by using the send API. Instead of holding the data until the whole message is collected, data can be sent in chunks. Sending data to ctxt.output by using the DATA event sends a partial protocol message. It can be followed by more DATA events. An EOM event must be sent to mark the end of the protocol message. The load balancing context downstream makes the load balancing decision on the first data received. A new load balancing decision is made after the receipt of the EOM message.

To stream protocol message data, send multiple DATA events followed by an EOM event. The contiguous DATA events and the following EOM event are sent to the same server connection selected by load balancing decision for the first DATA event in the sequence.

For a send to client context, EOM and DATA events are effectively the same, because there is no special handling by the client context downstream for EOM events.

Token based load balancing

For natively supported protocols, a Citrix ADC appliance supports a token based load balancing method that uses PI expressions to create the token. For extensions, the protocol is not known in advance, so PI expressions cannot be used. For token based load balancing, you have to set the default load balancing virtual server to use the USER_TOKEN load balancing method, and provide the token value from the extension code by calling the send API with a user_token field. If the token value is sent from the send API and the USER_TOKEN load balancing method is configured on the default load balancing virtual server, the load balancing decision is made by calculating a hash based on the token value. The maximum length of token value is 64 bytes.

```
add lb vserver v\\_mqttlb USER\\_TCP –lbMethod USER\\_TOKEN
```

The code snippet in the following example uses a send API to send an LB token value.

Example:

```
        -- send the message to lb

        -- user_token is set to do LB based on clientID

        ns.send(ctxt.output, "EOM", {
data = message,

                                user_token = token_info }
)
```

Load balancing persistence

Load balancing persistence is closely related to token based load balancing. Users have to be able to programmatically calculate the persistence session value and use it for load balancing persistence. The send API is used to send persistence parameters. To use load balancing persistence, you have to set the USERSESSION persistence type on the default load balancing virtual server and provide a persistence parameter from the extension code by calling the send API with a user_session field. The maximum length of the persistence parameter value is 64 bytes.

If you need multiple types of persistence for a custom protocol, you have to define user persistence types and configure them. The names of the parameters used to configure the virtual servers are decided by the protocol implementer. A parameter's configured value is also available to the extension code.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following CLI and code snippet shows the use of a send API to support load balancing persistence. The code listing in the section Code Listing for mqtt.lua also illustrates the use of the user_session field.

For persistency, you have to specify the USERSESSION persistency type on the load balancing virtual server and pass the user_session value from the ns.send API.

```
add lb vserver v\\_mqttlb USER\\_TCP –persistencetype USERSESSION
```

Send the MQTT message to the load balancer, with the user_session field set to clientID in the payload.

Example:

```
1 -- send the data so far to lb
2
3 -- user_session is set to clientID as well (it will be used to persist
     session)
4
5 ns.send(ctxt.output, " DATA " , {
6  data = data, user_session = clientID }
7  )
```

TCP connection based load balancing

For some protocols, MBLB might not be needed. Instead, you might need TCP connection based load balancing. For example, the MQTT protocol must parse the initial part of the TCP stream to determine the token for load balancing. And, all the MQTT messages on the same TCP connection must be sent to the same server connection.

TCP connection based load balancing can be achieved by using the send API with only DATA events and not sending any EOM. That way the downstream load balancing context bases the load balancing decision on the data received first, and sends all the subsequent data to the same server connection selected by the load balancing decision.

Also, some use cases might require the ability to bypass extension handling after the load balancing decision has been made. Bypassing the extension calls results in better performance, because the traffic is processed purely by native code. Bypass can be done by using the ns.pipe() API. A call to the pipe() API extension code can connect input context to an output context. After the call to pipe(), all the events coming from input context directly go to the output context. Effectively, the module from which the pipe() call is made is removed from the pipeline.

The following code snippet shows streaming and the use of the pipe() API to bypass a module. The code listing in the section Code Listing for mqtt.lua also illustrates how to do streaming and the use of pipe() API to bypass the module for rest of the traffic on the connection.

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
        -- send the data so far to lb
        ns.send(ctxt.output, "DATA", {
data = data,
                                        user_token = clientID }
)
        -- pipe the subsequent traffic to the lb - to bypass the client
            on_data handler
        ns.pipe(ctxt.input, ctxt.output)
```

Content based load balancing

For native protocols, content switching like feature for protocol extensions is supported. With this feature, instead of sending the data to the default load balance, you can send the data to the selected load balancer.

Content switching feature for protocol extensions is achieved by using the ctxt:lb_connect(<lbname>) API. This API is available to the TCP client context. Using this API, the extension code can obtain a load balancing context corresponding to an already configured load balancing virtual server. You can then use the send API with the load balancing context thus obtained.

The lb context can be NULL sometimes:

- Virtual server does not exists
- Virtual server is not of user protocol type
- Virtual server's state is not UP
- Virtual server is user virtual server, not load balancing virtual server

If you remove the target load balancing virtual server when it is in use, then all connections associated with that load balancing virtual server is reset.

The following code snippet shows the use of lb_connect() API. The code maps the client ID to load balancing virtual server names (lbname) using the Lua table lb_map and then gets the LB context for lbname using lb_connect(). And finally sends to the LB context using send API.

```
    local lb_map = {

       ["client1*"] = "lb_1",
       ["client2*"] = "lb_2",
       ["client3*"] = "lb_3",
       ["client4*"] = "lb_4"
     }

    -- map the clientID to the corresponding LB vserver and connect to
       it
    for client_pattern, lbname in pairs(lb_map) do
       local match_idx = string.find(clientID, client_pattern)
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
13         if (match_idx == 1) then
14        lb_ctxt = ctxt:lb_connect(lbname)
15        if (lb_ctxt == nil) then
16           error("Failed to connect to LB vserver: " .. lbname)
17        end
18        break
19         end
20     end
21     if (lb_ctxt == nil) then
22     -- If lb context is NULL, the user can raise an error or send data
          to default LB
23        error("Failed to map LB vserver for client: " .. clientID)
24     end
25 -- send the data so far to lb
26 ns.send(lb_ctxt, "DATA", {
27  data = data }
```

SSL

SSL for protocols using extensions is supported in ways similar to how SSL for native protocols is supported. Using the same parsing code for creating custom protocols, you can create a protocol instance over TCP or over SSL which can then be used to configure the virtual servers. Similarly, you can add user services over TCP or SSL.

For more information, see Configuring SSL Offloading for MQTT and Configuring SSL Offloading for MQTT With End-To-End Encryption.

Server connection multiplexing

Sometimes, the client sends one request at a time and sends the next request only after the response for the first request is received from the server. In such a case, server connection can be reused for other client connections, and for the next message on the same connection, after the response has been sent to the client. To allow reuse of server connection by other client connections, you must use the ctxt: reuse_server_connection() API on the server side context.

Note: This API is available in Citrix ADC 12.1 build 49.xx and later.

Modify traffic

To modify data in the request or response, you must use the native rewrite feature that uses an advanced policy PI expression. Because you cannot use PI expressions in extensions, you can use the following APIs to modify a TCP stream data.

```
1 data:replace(offset, length, new_string)
2 data:insert(offset, new_string)
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
data:delete(offset, length)
data:gsub(pattern, replace [,n]))
```

The following code snippet shows the use of replace() API.

```
-- Get the offset of the pattern, we want to replace
   local old_pattern = " pattern to repalace "
local old_pattern_length = old_pattern:len()
   local pat_off, pat_end = data:find(old_pattern)
   -- pattern is not present
if (not pat_off) then
    goto send_data
   end
  -- If the data we want to modify is not completely present, then
  -- wait for more data
  if (not pat_end) then
        ctxt:hold(data)
        data = nil
     goto done
  end
data:replace(pat_off, old_pattern_length, " new pattern ")
::send_data::
ns.send(ctxt.output, " EOM " , {
 data = data }
 )
::done::
```

The following code snippet shows the use of insert() API.

```
data:insert(5, " pattern to insert ")
```

The following code snippet shows the use of insert() API, when we want to insert after or before some pattern:

```
-- Get the offset of the pattern, after or before which we want to
    insert
   local pattern = " pattern after/before which we need to insert "
local pattern_length = pattern:len()
   local pat_off, pat_end = data:find(pattern)
-- pattern is not present
   if (not pat_off) then
    goto send_data
   end
  -- If the pattern after which we want to insert is not
  -- completely present, then wait for more data
  if (not pat_end) then
        ctxt:hold(data)
        data = nil
     goto done
  end
-- Insert after the pattern
data:insert(pat_end + 1, " pattern to insert ")
   -- Insert before the pattern
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
data:insert(pat_off, "pattern to insert")
::send_data::
    ns.send(ctxt.output, "EOM", {
 data = data }
 )
::done::
```

The following code snippet shows the use of delete() API.

```
-- Get the offset of the pattern, we want to delete
   local delete_pattern = "pattern to delete"
local delete_pattern_length = delete_pattern:len()
   local pat_off, pat_end = data:find(old_pattern)
   -- pattern is not present
if (not pat_off) then
          goto send_data
   end
  -- If the data we want to delete is not completely present,
  -- then wait for more data
  if (not pat_end) then
       ctxt:hold(data)
       data = nil
    goto done
  end
data:delete(pat_off, delete_pattern_length)
::send_data::
ns.send(ctxt.output, "EOM", {
 data = data }
 )
::done::
```

The following code snippet shows the use of gsub() API.

```
    -- Replace all the instances of the pattern with the new string
data:gsub("old pattern", "new string")
-- Replace only 2 instances of "old pattern"
data:gsub("old pattern", "new string", 2)
-- Insert new_string before all instances of "http"
data:gsub("input data", "(http)", "new_string%1")
-- Insert new_string after all instances of "http"
data:gsub("input data", "(http)", "%1new_string")
-- Insert new_string before only 2 instances of "http"
data:gsub("input data", "(http)", "new_string%1", 2)
```

Note: This API is available in Citrix ADC 12.1 build 50.xx and later.

Originate traffic to client or server

You can use the ns.send() API to send data that originates from the extension code to a client and a back-end server. To send or receive response directly with a client, from client context, you must use ctxt.client as the target. To send or receive response directly with a back-end server from server

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

context, you must use ctxt.server as the target. The data in the payload can be a TCP stream data or a Lua string.

To stop traffic processing on a connection, you can use ctxt:close() API from either the client or the server context. This API closes the client-side connection or any server connections linked to it.

When you call the ctxt:close() API, extension code sends TCP FIN packet to the client and server connections and if more data is received from the client or server on this connection, then the appliance resets the connection.

The following code snippet shows the use of ctxt.client and ctxt:close() APIs.

```
    -- If the input packet is not MQTT CONNECT type, then
-- send some error response to the client.
function client.on_data(ctxt, payload)
    local data = payload.data
    local offset = 1
    local msg_type = 0
    local error_response = "Missing MQTT Connect packet."
    byte = data:byte(offset)
msg_type = bit32.rshift(byte, 4)
if (msg_type ~= 1) then
-- Send the error response
   ns.send(ctxt.client, "DATA", {
 data = error_response }
 )
-- Since error response has been sent, so now close the connection
    ctxt:close()
end
```

The following code snippet shows the example when user can inject the data in the normal traffic flow.

```
-- After sending request, send some log message to the server.
function client.on_data(ctxt, payload)
local data = payload.data
local log_message = "client id : "..data:sub(3, 7).." user name : "
    data:sub(9, 15)
-- Send the request we get from the client to backend server
ns.send(ctxt.output, "DATA", {
 data = data }
 )
After sending the request, also send the log message
ns.send(ctxt.output, "DATA", {
 data = log_message" }
 )
end
```

The following code snippet shows the use of ctxt.to_server API.

```
-- If the HTTP response status message is "Not Found",
-- then send another request to the server.
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
function server.on_data(ctxt, payload)
    local data = payload.data
    local request  " GET /default.html HTTP/1.1\r\n\r\n " ss
    local start, end = data:find( " Not Found " )
    if (start) then
    -- Send the another request to server
        ns.send(ctxt.server,  " DATA " , {
 data = request }
 )
end
```

Note: This API is available in Citrix ADC 12.1 build 50.xx and later.

Data processing on the connection establishment

There might be a use case where you want to send some data at the connection establishment (when the final ACK is received). For example, in proxy protocol, you might want to send client's source and destination IP addresses and ports to the back-end server at the connection establishment. In this case, you can use client.init() callback handler to send the data on connection establishment.

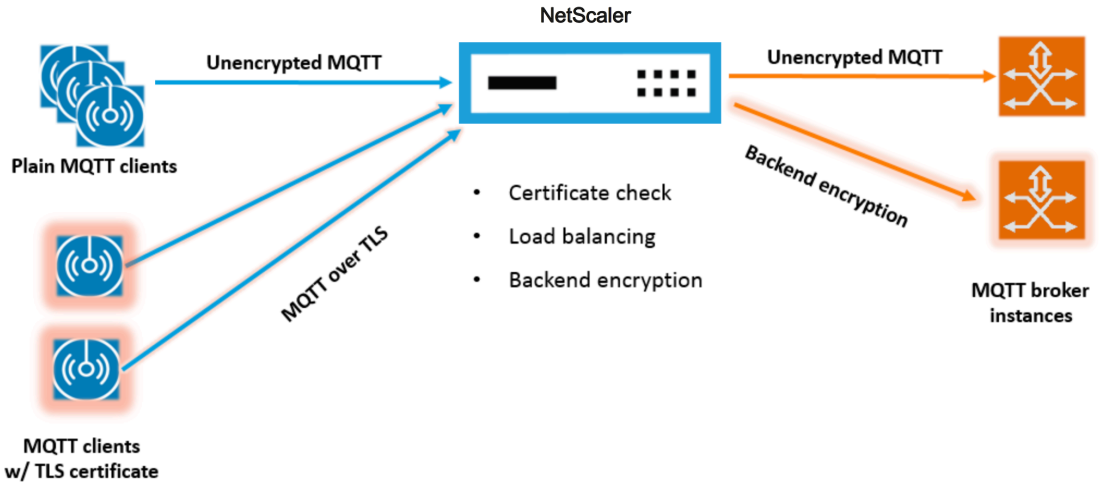
The following code snippet shows the use of client.init() callback:

```
-- Send a request to the next processing context
-- on the connection establishment.
function client.init(ctxt)
   local request  " PROXY TCP4 "  + ctxt.client.ip.src.to_s +  "   "  +
      ctxt.client.ip.dst.to_s +  "   "  + ctxt.client.tcp.srcport +  "   "
       +     ctxt.client.tcp.dstport
-- Send the another request to server
   ns.send(ctxt.output,  " DATA " , {
 data = request }
 )
  end
```

Note: This API is available in Citrix ADC 13.0 build xx.xx and later.

Tutorial –Add MQTT protocol to the Citrix ADC appliance by using protocol extensions

September 14, 2021



The command line interface (CLI) commands for custom protocol use the keyword "user"to signify the user defined nature of the underlying configuration entities. With the help of extension code, you can add a new user protocol to the system and add user virtual servers for user-defined protocols. The

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

user virtual servers are in turn configurable by setting parameters. Configured values for virtual server parameters are available in the extension code.

MQTT protocol is used for illustration purposes.

The following diagram illustrates a Citrix ADC appliance and MQTT client and broker tools.

Code listing for mqtt.lua

September 14, 2021

The code listing below, mqtt.lua, gives the code to implement the MQTT protocol on Citrix ADC using protocol extensions. The code only has the TCP client data callback function defined - client.on_data(). For server data, it does not add a callback function and the server to client takes the fast native path. For client data, the code parses the CONNECT MQTT protocol message and extracts the ClientID. It then uses the ClientID for user_token value, which is used to load balance all the client traffic for the connection based on the ClientID by setting LB method for the LB vserver as USER_TOKEN. It uses the ClientID also for user_session value, which can be used for LB persistence by setting persistence type for the LB vserver as USERSESSION. The code uses the ns.send() to do LB and send the initial data. It uses the ns.pipe() API to send the rest of the client traffic directly to server connection, bypassing calls to extension callback handler.

```
--[[

  MQTT event handler for TCP client data

    ctxt - TCP client side App processing context.

    data - TCP Data stream received.
```

Configure MQTT by using protocol extensions

August 21, 2024

The following steps add a MQTT protocol to the Citrix ADC appliance.

Import the extension file to the Citrix ADC appliance, from either a web server (using HTTP) or your local workstation. For details about importing the extension file, see Import extensions.

```
import ns extension local:mqtt_generic_fs.lua mqtt_code
```

Add a new user TCP based protocol to the system by using the extension.

```
add user protocol MQTT -transport TCP -extension mqtt_code
```

Add a service of type USER_TCP to indicate that this is a user-defined protocol.

```
add service s1 10.102.90.112 USER_TCP 80
```

Add a user load balancing vserver and bind backend services to it.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add lb vs mysv USER_TCP

bind lb vs mysv s1
```

Add a user virtual server for the newly added protocol and make the load balancing virtual server configured in the previous step the default load balancer.

```
add user vs v_mqtt MQTT 10.217.24.28 80 -defaultlb mysv
```

Optionally, enable MQTT session persistence based on ClientID, set the persistence type to USERSESSION.

```
set lb vserver mysv -persistenceType USERSESSION
```

Configuring SSL offloading for MQTT

September 14, 2021

You can implement SSL offloading for user protocols by adding an SSL instance for the protocol. The example below shows how to do SSL offloading for a user protocol. The traffic to backend services is unencrypted with this configuration.

Note: This example does not provide details related to adding or updating a certificate-key pair and binding it to a virtual server. For those details, see SSL certificates.

The following commands add the MQTT_SSL protocol by including mqtt.lua with transport value "SSL."

```
import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
add user protocol MQTT_SSL -transport SSL -extension mqtt_code
```

The following commands add a user load balancing virtual server and bind backend services to it.

```
add service mqtt_svr1 10.217.24.48 USER_TCP 1501
add service mqtt_svr2 10.217.24.48 USER_TCP 1502
add lb vserver mqtt_lb USER_TCP  – lbMethod ROUNDROBIN
bind lb vserver mqtt_lb mqtt_svr1
bind lb vserver mqtt_lb mqtt_svr2
```

The following command adds a user virtual server for the newly added protocol MQTT_SSL. Using MQTT_SSL means the Citrix ADC appliance will do SSL offloading, because MQTT_SSL was configured with SSL transport. The command also sets the defaultlb to the load balancing virtual server configured in the previous step.

```
add user vserver mqtt_vs MQTT_SSL 10.217.24.28 8765 -defaultLb
mqtt_lb
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For SSL offloading, you also need to enable the SSL feature and bind a certkey to the user virtual server. For more information, see the following topics:

Add or update a certificate-key pair

Bind the certificate-key pair to the SSL virtual server

Example:

```
enable ns feature SSL

add SSL certKey mqtt_svr_cert_key -cert server1.cert -key server1.key

bind ssl vserver mqtt_vs  -certkeyName mqtt_svr_cert_key
```

Configuring SSL offloading with end-to-end encryption for MQTT

September 14, 2021

The following example shows how to do SSL offloading for MQTT with end-to-end encryption.

Note: This example does not provide details related to adding or updating a certificate-key pair and binding it to a virtual server. For those details, see SSL certificates.

The following commands import the extension file and add the MQTT_SSL protocol with SSL transport.

```
import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
add user protocol MQTT_SSL -transport SSL -extension mqtt_code
```

The following commands add a user load balancing virtual server and bind backend services to it. Both the load balancing virtual server and the services are configured for the service type USER_SSL_TCP.

```
add service mqtt_svr1 10.217.24.48 USER_SSL_TCP 1501
add service mqtt_svr2 10.217.24.48 USER_SSL_TCP 1502
add lb vserver mqtt_lb USER_SSL_TCP – lbmethod RR
bind lb vserver mqtt_lb mqtt_svr1
bind lb vserver mqtt_lb mqtt_svr2
```

The following command adds a user virtual server for the newly added protocol MQTT_SSL. Using MQTT_SSL means the Citrix ADC appliance will do SSL offloading, because MQTT_SSL was configured with SSL transport. The command also makes the load balancing virtual server, configured in previous step, the default load balancer.

```
add user vserver mqtt_vs MQTT_SSL 10.217.24.28 8765 -defaultLb
mqtt_lb
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For end-to-end encryption, you also need to enable the SSL feature and bind a certkey to the user and default load balancing virtual servers. For more information, see the following topics:

Add or update a certificate-key pair

Bind the certificate-key pair to the SSL virtual server

```
enable ns feature SSL

add SSL certKey mqtt_svr_cert_key -cert server1.cert -key server1.key

bind ssl vserver mqtt_lb  -certkeyName mqtt_svr_cert_key

bind ssl vserver mqtt_vs  -certkeyName mqtt_svr_cert_key
```

Tutorial - load balancing syslog messages by using protocol extensions

September 14, 2021

Syslog protocol available on the Citrix ADC appliance works only for the messages generated on the Citrix ADC appliance. It does not load balance the messages coming from external nodes. To load balance such messages, you need to use the protocol extensions feature and write the syslog message parsing logic by using the Lua 5.2 programming language.

Code for parsing syslog message

The code only has the TCP client data callback function defined - client.on_data(). For server data, it does not add a callback function and the server to client takes the fast native path. The code identifies message boundary based on the trailing character. If the TCP packet contains more than one syslog messages, then we split the packet based on the trailing character and load balance each message.

```
--[[

  Syslog event handler for TCP client data

    ctxt - TCP client side App processing context.

    data - TCP Data stream received.

--]]

function client.on_data(ctxt, payload)

                  local message = nil

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
15                    local data_len
16
17                    local data = payload.data
18
19                    local trailing_character = "\n"
20
21                    ::split_message::
22
23                                        -- Get the offset of trailing
                                             character
24
25                                        local new_line_character_offset =
                                             data:find(trailing_character)
26
27                                        -- If trailing character is not
                                             found, then wait for more data.
28
29                                        if (not new_line_character_offset)
                                             then
30
31                                                                goto
                                                                     need_more_data
32
33                                        end
34
35                                        -- Get the length of the current
                                             message
36
37                                        data_len = data:len()
38
39                                        -- Check whether we have more than
                                             one message
40
41                                        -- by comparing trailing character
                                             offset and
42
43                                        -- current data length
44
45                                        if (data_len >
                                             new_line_character_offset) then
46
47                                                                -- If we have
                                                                     more than one
                                                                     message, then
                                                                     split
48
49                                                                -- the data into
                                                                     two parts such
                                                                      that first
                                                                     part
50
51                                                                -- will contain
                                                                     message upto
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
                                                                trailing
                                                                character
52
53                                                          -- offset and
                                                                second part
                                                                will contain
54
55                                                          -- remaining
                                                                message.
56
57                                                          message, data =
                                                                data:split(
                                                                new_line_character_offse
                                                                )
58
59                                      else
60
61                                                          message = data
62
63                                                          data = nil
64
65                                      end
66
67  -- Send the data to the backend server.
68
69                                      ns.send(ctxt.output, "EOM", {
70   data = message }
71   )
72
73                                      goto done
74
75                                      ::need_more_data::
76
77                                                          -- Wait for more
                                                                data
78
79                                                          ctxt:hold(data)
80
81                                                          data = nil
82
83                                                          goto done
84
85                                      ::done::
86
87                                                          -- If we have
                                                                more data to
                                                                parse,
88
89                                                          -- then do
                                                                parsing again.
90
91                                                          if (data) then
92
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
93                                                
```

```
show lb persistentSessions [<vserv-name>]
```

- **CLI command:**

  ```
  add user protocol <name> -transport ( TCP | SSL )-extension <
  string> -comment <string>]>
  ```

- **Description:**

  Adds a new user protocol to the Citrix ADC appliance by using extensions. Currently only user protocols with transport value TCP or SSL are supported.

  > **Example:**
  >
  > add user protocol MQTT -transport TCP -extension mqtt_code

- **CLI command:**

  ```
  rm user protocol <name>
  ```

- **Description:**

  Removes a user protocol previously added to the Citrix ADC appliance.

  > **Example:**
  >
  > rm user protocol mqtt

- **CLI command:**

  ```
  set user protocol <name> -comment <string>
  ```

- **Description:**

  Changes settings for a user protocol previously added to the Citrix ADC appliance.

  > **Example:**
  >
  > set user protocol mqtt -comment “MQTT protocol implementation”

- **CLI command:**

  ```
  unset user protocol <name> -comment
  ```

- **Description:**

  Removes settings for a user protocol previously added to the Citrix ADC appliance.

  > **Example:**
  >
  > unset user protocol mqtt -comment “MQTT protocol implementation”

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **CLI command:**

```
update ns extension <extension name>
```

- **Description:**

  Updates the implementation for a previously added user protocol by using extensions.

  You can update the protocol implementation only if the protocol is not being used by any user virtual server.

  > **Example:**
  >
  > update ns extension my-extension

- **CLI command:**

```
add lb vserver <name> [USER_TCP | USER_SSL_TCP] [-lbmethod
USER_TOKEN] [-persistencetype USERSESSION] [-timeout <value>]
```

- **Description:**

  Adds a load balancing virtual server to the Citrix ADC appliance. This is an existing CLI command.

  For load balancing user virtual servers, the service type to use is USER_TCP or USER_SSL_TCP. The IP address and port are not allowed with user load balancing virtual servers.

  For user load balancing virtual servers, only the ROUNDROBIN load balancing method is allowed, and the token value is provided by the extension code. Similarly, only USERSESSION persistence is allowed, and the persistence setting is provided by the extension code.

  > **Example:**
  >
  > add lb vserver mysv USER_TCP –lbmethod ROUNDROBIN

- **CLI command:**

```
add user vserver <name> <userProtocol> <IPAddress> <port> -
defaultLB <string> [-params <string>] [-comment <string>]
```

- **Description:**

  Adds a virtual server for a user protocol by using extensions. The configured default user load balancing virtual server is available to the TCP client data extension handler as ctxt.output. For a virtual server, extension parameters can be set by using the -params option with a name and a value pair. The corresponding parameter value is available to the extension handlers as ctxt.vserver.params.<paramName>.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Example:**
>
> add user vs v_mqtt MQTT 10.217.24.28 80 -defaultlb mysv

- **CLI command:**

```
rm user vserver <name>
```

- **Description:**

Removes a user virtual server previously added to to the Citrix ADC appliance.

> **Example:**
>
> rm user vserver v_mqtt

- **CLI command:**

```
set user vserver <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-
defaultLB <string>] [-params <string>] [-comment <string>]
```

- **Description:**

Changes settings for a user virtual server previously added to to the Citrix ADC appliance. When an extension parameter is assigned a new value by the -params option, the old value is overwritten.

> **Example:**
>
> set user vs v_mqtt MQTT 10.217.24.28 -defaultlb mysv -comment “MQTT protocol implementation”

- **CLI command:**

```
unset user vserver <name> [-params] [-comment]
```

- **Description:**

Removes the settings for a user virtual server previously added to to the Citrix ADC appliance. If you use the –params option to unset an extension parameter, the corresponding parameter value available to extension handlers is changed to nil.

> **Example:**
>
> unset user vs v_mqtt MQTT 10.217.24.28 -defaultlb mysv -comment “MQTT protocol implementation”

- **CLI command:**

```
show user protocol [<name>]
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Description:**

  Displays information about a user protocol, such as extension and callbacks.

  > **Example:**
  >
  > show user protocol mqtt

- **CLI command:**

  ```
  show user vserver [<name>]
  ```

- **Description:**

  Displays information about a user virtual server.

  > **Example:**
  >
  > show user vserver vs_mqtt

- **CLI command:**

  ```
  stat user vserver [<name>]
  ```

- **Description:**

  Displays statistics about a user virtual server.

  > **Example:**
  >
  > stat user vserver vs_mqtt

- **CLI command:**

  ```
  show lb persistentSessions [<vserv-name>]
  ```

- **Description:**

  Displays information about persistent sessions. This is an existing CLI. For user protocols, the persistence type is shown as USERSESSION.

- **CLI command:**

  ```
  rm lb vserver <name>
  ```

- **Description:**

  Removes a user LB vserver previously added to the Citrix ADC appliance.

  > **Example:**
  >
  > rm lb vserver mysv

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **CLI command:**

```
add service <name> <IPAddr> (USER_TCP | USER_SSL_TCP)<Port>
```

- **Description:**

  Adds a backend service to be used for a user protocol. This is an existing CLI command with new service types USER_TCP and USER_SSL_TCP.

  > **Example:**
  >
  > add service mqtt_svr1 10.217.24.48 USER_TCP 1501
  >
  > **Note**: The existing "set service and unset service"commands can be used to remove or change the settings of a previously added service for a user protocol.

- **CLI command:**

```
bind lb vserver <name> <serviceName>
```

- **Description:**

  Binds a service to a user LB vserver. The service type should be USER_TCP/USER_SSL_TCP for binding to an LB vserver with type of USER_TCP/USER_SSL_TCP.

  > **Example:**
  >
  > bind lb vserver mysv mqtt_svr1

- **CLI command:**

```
unbind lb vserver <name> <serviceName>
```

- **Description:**

  Unbinds a previously bound service to a user LB vserver.

  > **Example:**
  >
  > unbind lb vserver mysv mqtt_svr1

- **CLI command:**

```
rm service <name>
```

- **Description:**

  Removes a service that is previously added for a user protocol.

  > **Example:**
  >
  > rm service mqtt_svr1

Troubleshooting protocol extensions

September 14, 2021

If your extension function is not behaving as expected, you can use extension tracing functionality to verify the behavior of your extension function. You can also add logging to your extension function by using the custom logging functionality, where you can define the log level to be captured on the Citrix ADC appliance.

Custom logging

You can also add your own logging to your extension function. To do so, use the built-in ns.logger:level() function, where level is emergency , alert , critical , error , warning , notice , info , or debug . The parameters are the same as the C printf() function: a format string, and a variable number of arguments to supply values for the % specified in the format string. For example, you might add the following to the COMBINE_HEADERS function to log the result of a call:

```
local result\_str = table.concat(combined\_headers, "\\r\\n") .. "\\r\\
   n\\r\\n"

ns.logger:info("Result: %s", result\_str)

return result\_str
```

The above function would log the following message to/var/log/ns.log for the sample input shown in the abbreviated log messages examples in the Extension Tracing section above.

```
... : default NSEXTENSION Message 143 0 : "Result: Host: 10.217.24.7:2000^
M H1: abcd, 1234^M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4)
libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3^M Accept: \*/\*^M H2: h2val1
, h2val2, h2val3^M ^M"
```

Policy extensions

September 14, 2021

The policy extension feature enables you to write extension functions for built-in policy types. The extensions can be used in policy expressions, just like built-in functions. They are executed when the corresponding policy expressions are evaluated. This feature is useful for:

- Adding customized functions to existing Policies.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Implementing logical constructs for complex customer requirements.

The policy extension feature addresses these limitations by enabling users to write extension functions for built in Policy types. The extensions can then be used in the policy expressions, just like built-in functions. They are executed when the corresponding policy expressions are evaluated.

The following table lists the policy types that can be used when writing an extension, and their associated mappings.

Policy Type	Mapped Policy Type	Output
TEXT_T	NSTEXT	String
BOOL_AT	NSBOOL	Boolean
NUM_AT	NSNUM	Number (double-precision floating point)
DOUBLE_AT	NSDOUBLE	Number (double-precision floating point)

Prerequisites for using policy extensions

The imported functions must conform to the existing policy standards. Therefore:

- The function name must start with a letter and may contain numbers or underscores.
- The function name is treated as case insensitive by Citrix ADC policies.
- The function must return a single value even if the extension language returns multiple values.
- Functions with a variable number of arguments are not supported.

How do policy extensions work?

The existing policies on a Citrix ADC appliance use an interpreter to evaluate the functions, which are imported in a policy extension file. When a user imports a new function in a policy extension file:

1. The extension file is validated for syntax and other conditions.
2. If the validation fails, the error is reported to the user.
3. If the validation succeeds, the extension file is imported to the Citrix ADC appliance and its contents can be used in policy expressions, just like any built-in policy function

    a) If the policy expression evaluation returns an error during runtime, it is reported as an undef event and the associated error counter is incremented.

    Note: If a policy undef event occurs and the policy rule contains one or more policy extension functions, the `show ns extension <name>` command displays the undef hits

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

when applied to those policy extensions. If the extension function is aborted, the abort counter value is incremented.

b) If the policy expression evaluation is successful, expression evaluation resumes until the entire expression is evaluated, or until it is aborted because of an error.

If the extension function takes too long to run, it is aborted, and the error counter pertaining to that extension function is incremented. The extension function is sandboxed, which prevents:

- Excessive CPU usage on the Citrix ADC appliance.
- Excessive memory usage on the Citrix ADC appliance.
- Usage of harmful built-in libraries or third-party libraries or binaries.
- Long-running scripts that could potentially cause the Citrix ADC appliance to reboot.

Configuring policy extensions

September 5, 2024

When your policy extension file is ready, import it to the Citrix ADC appliance. The import process copies the extension file into a directory on the Citrix ADC appliance and checks for syntax errors.

After the import, you have to make the extension file available for use in the policy expressions.

> **Note:**
>
> - Use the **`import`** command to download the file content from an external source \<src\>, or an internal source, onto the NetScaler file system.
> - Use the `add` command to load the file content into one or more packet engines for the first time.
> - If the file content is updated, you can download the new content to the NetScaler file system by using the **`import`** command with the overwrite argument.
> - Use the `update` command to load the updated content to one or more packet engines.

Configure policy extensions by using the CLI

1. Import the policy extension file to the Citrix ADC Appliance, from either a web server (using HTTP) or your local workstation.

   a) HTTP Import

   If you have a web server available, you can store the extension file in the webserver directory and import it to the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
import ns extension <src> <name> [-comment<string>] [-
   overwrite]
```

Example:

```
import ns extension http://myhost/path/to/extension
   myextension -comment "Custom crc calculation"
```

b) Local Import

You can use the SSH client to copy the extension file from your workstation to the /var/tmp directory of the Citrix ADC appliance

```
scp extension-file-name <ns-userid@ns-ip-addr>:/var/tmp
```

where,

- extension-file-name is the name of the extension file on your client machine.
- ns-userid is the Citrix ADC appliance user with permission to write to /var/tmp.
- ns-ip-addr is the Citrix ADC IP address.

After copying the file to the Citrix ADC appliance, run the import command on the Citrix ADC appliance.

```
import ns extension local:<extension-file-name> <extension-
   name>
```

> **Note:**
>
> The CLI must be used to import a local extension file, by running the **import** command.

2. Add the policy extension to the packet engine for evaluation.

```
add ns extension <name> [-comment <string>]
```

Example:

```
add ns extension myextension
```

After an extension file is imported, you can update it, if you included the -overwrite parameter in the import command, or remove it. You can also display the details of an imported extension file.

Update an extension file on the Citrix ADC appliance from the source

At the command prompt, type:

```
update ns extension <name>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:**
>
> You can update the extension file only after importing the specified extension file to the NetScaler appliance with the -overwrite parameter.

Example:

```
update ns extension myextension
```

Remove an extension file from the Citrix ADC appliance

At the command prompt type:

```
rm ns extension <name>
```

Example:

```
rm ns extension myextension
```

Display the details of the specified extension function on the Citrix ADC appliance

At the command prompt, type:

```
show ns extension <name>
```

Example:

```
show ns extension myextension
```

Configure policy extensions by using the GUI

1. Import the policy extension file to the Citrix ADC Appliance, from either a web server (using HTTP) or your local workstation.

   a) Navigate to **AppExpert** > **Policy Extensions**, click **Policy Extension**, from the **Import From** drop-down list, select the URL for the location of the extension file that you want to import.

   b) Navigate to **AppExpert** > **Policy Extensions**, and on the **Policy Extension** tab, import the extension file by selecting **File** in the **Import From** drop-down list.

2. Add the policy extension to the packet engine for evaluation.

   Navigate to **AppExpert** > **Policy Extensions**, and on the **Policy Extensions** tab, add the extension file.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Update an extension file on the Citrix ADC appliance from the source

Navigate to **AppExpert** > **Policy Extensions**, and on the **Policy Extensions** tab, update the extension file.

Remove an extension file from the Citrix ADC appliance

Navigate to **AppExpert** > **Policy Extensions**, and on the **Policy Extensions** tab, remove the extension file.

Display the details of the specified extension function on the Citrix ADC appliance

Navigate to **AppExpert** > **Policy Extensions**, and on the **Policy Extensions Functions** tab, click the drop-down list arrow of the extension function that you want to see the details.

Policy extensions - use cases

September 14, 2021

Certain customer applications have requirements that cannot be addressed with existing policies and expressions. The policy extension feature enables customers to add customized functions to their applications to meet their requirement.

The following use cases illustrate the addition of new functions using the policy extension feature on the Citrix ADC appliance.

- Case 1: Custom hash
- Case 2: Collapse double slashes in URLs
- Case 3: Combine headers

Case 1: Custom hash

The CUSTOM_HASH function provides a mechanism to insert any type of hash value in the responses sent to the client. In this use case, the hash function is used to compute the hash of the query string for a rewrite HTTP request and insert an HTTP header named CUSTOM_HASH with the computed value. The CUSTOM_HASH function implements the DJB2 hash algorithm.

Sample Usage of CUSTOM_HASH:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> add rewrite action test_custom_hash insert_http_header "CUSTOM_HASH"
   "HTTP.REQ.URL.QUERY.CUSTOM_HASH"
```

Sample Definition of CUSTOM_HASH():

```
    -- Extension function to compute custom hash on the text

    -- Uses the djb2 string hash algorithm
    function NSTEXT:CUSTOM_HASH() : NSTEXT

        local hash = 5381

        local len = string.len(self)

        for i = 1, len do

             hash = bit32.bxor((hash * 33), string.byte(self, i))

        end

        return tostring(hash)

    end
```

Line-by-line description of the above sample:

```
function NSTEXT:CUSTOM_HASH() : NSTEXT

Defines the CUSTOM_HASH() function, with text input and a text return
   value.

local hash = 5381
local len = string.len(self)

Declares two local variables:

 - hash. Accumulates the compute hash value and is seeded with the
    number 5381

 - len. Sets to the length of the self input text string, using the
    built-in string.len() function.

for i = 1, len do
      hash = bit32.bxor((hash * 33), string.byte(self, i))
end

Iterates through each byte of the input string and adds the byte to the
    hash. It uses the built-in string.byte() function to get the byte
   and the built-in bit32.bxor() function to compute the XOR of the
   existing hash value (multiplied by 33) and the byte.

return tostring(hash)

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
22 Calls the built-in tostring() function to convert the numeric hash
      value to a string and returns the string as the value of the
      function.
```

Case 2: Collapse double slashes in URLs

Collapsing double slashes in URLs improves the website rendering time, because browsers parse the single slash URLs more efficiently. The single slash URLs also to maintain compatibility with applications that do not accept double slashes. The policy extension feature allows customers to add a function that replaces the double slashes with single slashes in the URLs. The following example illustrates the addition of a policy extension function that that collapses double slashes in URLs.

Sample Definition of COLLAPSE_DOUBLE_SLASHES():

```
1     -- Collapse double slashes in URL to a single slash and return the
         result
2     function NSTEXT:COLLAPSE_DOUBLE_SLASHES() : NSTEXT
3
4         local result = string.gsub(self, "//", "/")
5
6         return result
7
8     end
```

Line-by-line description of the above sample:

```
1  function NSTEXT:COLLAPSE_DOUBLE_SLASHES() : NSTEXT
2
3  Declares the COLLAPSE_DOUBLE_SLASHES() function with text input and
      return.
4
5  local result = string.gsub(self, "//", "/")
6
7  Declares a local variable named result and uses the built-in string.
      gsub() function to replace all double slashes with single slashes in
       the self input text.
8
9  The second parameter of string.gsub() is actually a regular expression
      pattern, although here a simple string is used for the pattern.
10
11 return result
12
13 Returns the resulting string.
```

Case 3: Combine headers

Certain customer applications cannot handle multiple headers in a request. Also, parsing of duplicate headers with same header values, or multiple headers with same name but different values in a

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

request, consumes time and network resources. The policy extension feature allows customers to add a function to combine these headers into single headers with a value combining the original values. For example, combining the values of the headers H1 and H2.

Original request:

```
GET /combine_headers HTTP/1.1
User-Agent: amigo unit test
Host: myhost
H2: h2val1
H1: abcd
Accept: */*
H2: h2val2
Content-Length: 0
H2: h2val3
H1: 1234
```

Modified request:

```
GET /combine_headers HTTP/1.1
User-Agent: amigo unit test
Host: myhost
H2: h2val1, h2val2, h2val3
H1: abcd, 1234
Accept: */*
Content-Length: 0
```

In general, this type of request modification is done using the Rewrite feature, using policy expressions to delineate the part of the request to be modified (the target) and the modification to be performed (the string builder expression). However, policy expressions do not have the ability to iterate over an arbitrary number of headers.

The solution to this problem requires an extension to the policy facility. To do this, we will define an extension function, called COMBINE_HEADERS. With this function, we can set up the following rewrite action:

```
> add rewrite action combine_headers_act replace 'HTTP.REQ.FULL_HEADER
.AFTER_STR("HTTP/1.1rn")''HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1rn
").COMBINE_HEADERS'
```

Here, the rewrite target is HTTP.REQ.FULL_HEADER.AFTER_STR(“HTTP/1.1rn”). The AFTER_STR(“HTTP/1.1rn”) is required because FULL_HEADER includes the first line of the HTTP request (e.g. GET /combine_headers HTTP/1.1).

The string builder expression is HTTP.REQ.FULL_HEADER.AFTER_STR(“HTTP/1.1rn”).COMBINE_HEADERS, where the headers (minus the first line) are fed into the COMBINE_HEADERS extension function, which combines and returns the values for headers.

Sample Definition of COMBINE_HEADERS():

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
    -- Extension function to combine multiple headers of the same name into one header.

    function NSTEXT:COMBINE_HEADERS(): NSTEXT

        local headers = {
}
-- headers

        local combined_headers = {
}
-- headers with final combined values
        -- Iterate over each header (format "name:valuer\r\n")

        -- and build a list of values for each unique header name.

        for name, value in string.gmatch(self, "([^:]+):([^\r\n]*)\r\n") do

            if headers[name] then

                local next_value_index = #(headers[name]) + 1

                headers[name][next_value_index] = value

            else

                headers[name] = {
name .. ":" .. value }

            end

        end

        -- iterate over the headers and concat the values with separator ","

        for name, values in pairs(headers) do

            local next_header_index = #combined_headers + 1

            combined_headers[next_header_index] = table.concat(values, ",")

        end

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
50          -- Construct the result headers using table.concat()
51
52          local result_str = table.concat(combined_headers, "\r\n") .. "\
                r\n\r\n"
53
54          return result_str
55
56      end
```

Line-by-line description of the above sample:

```
1  function NSTEXT:COMBINE_HEADERS(): NSTEXT
2
3  Defines the COMBINE_HEADERS extension function, with the text input
       into the function from the policy expression and a text return type
       to the policy expression.
4
5  local headers = {
6    }
7    -- headers
8  local combined_headers = {
9    }
10   -- headers with final combined values
11
12 Declares local variables headers and combined_headers and initialize
       these variables to empty tables. headers will be a table of arrays
       of strings, where each array holds one or more values for a header.
       combined_headers will be an array of strings, where each array
       element is a header with its combined values.
13
14 for name, value in string.gmatch(self, "([^:]+):([^\r\n\]*)\r\n") do
15 . . .
16 end
```

This generic for loop parses each header in the input. The iterator is the built-in string.gmatch() function. This function takes two parameters: a string to search, and a pattern to use to match pieces of the string. The string to search is supplied by the implicit self parameter, which is the text for the headers input into the function.

The pattern is expressed using a regular expression (regex for short). This regex matches the header name and value for each header, which the HTTP standard defines as `*name*:*value*\r\n`. The parentheses in the regex specify the matching parts to be extracted, so the regex schematic is (*match-name*):(*match-value*)\r\n. The *match-name* pattern needs to match all characters except the colon. This is written [^:]+([^:] is any character except : and + is one or more repetitions). Similarly, the *match-value* pattern has to match any characters except the \r\n, so it is written [^\r\n] ([^\r\n] matches any character except \r and \n and * is zero or more repetions). This makes the complete regex `([^:]+):([^\r\n]*)\r\n`.

The for statement uses a multiple assignment to set name and value to the two matches returned by the string.gmatch() iterator. These are implicitly declared as local variables within the body of the for

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

loop.

```
if headers[name] then
     local next_value_index = #(headers[name]) + 1
     headers[name][next_value_index] = value
else
     headers[name] = {
 name .. ":" .. value }

end
```

These statements within the for loop put the header names and values into the headers table. The first time a header name is parsed (say H2: h2val1 in the example input), there is no headers entry for the name and headers[name] is nil.

Since nil is treated as false, the else clause is executed. This sets the headers entry for name to an array with one string value *name*:*value.*

Note: The array constructor in the else loop is equivalent to {[1] = name .. ":".. value}, which sets the first element of the array.) For the first H2 header, it sets headers["H2"] = {"H2:h2val1"}.

On subsequent instances of a header, (say, H2: h2val2 in the example input). headers[name] is not nil, so the then clause is executed. This determines the next available index in the array value for headers[name], and puts the header value into that index. For the second H2 header, it sets headers["H2"] = {"H2:h2val1", "h2val2"}.

```
for name, values in pairs(headers) do
    local next_header_index = #combined_headers + 1
    combined_headers[next_header_index] = table.concat(values, ",")
end
```

After the original headers have been parsed and the headers table filled in, this loop builds the combined_headers array. It uses the pairs() function as the for loop iterator.

Each call to pairs() returns the name and value of the next entry in the headers table.

The next line determines the next available index in the combined_headers array, and the next line sets that array element to the combined header. It uses the built-in table.concat() function, which takes as its arguments an array of strings and a string to use as a separator, and returns a string that is the concatenation of the array strings, separated by the separator.

For example, for values = {"H2:h2val1", "h2val2"}, this produces "H2:h2val1, h2val2"

```
local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"
```

After the combined_headers array are built, it concatenates the elements into one string, and adds a double \r\n that terminates the HTTP headers.

```
return result_str
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Returns a string as the result of the COMBINE_HEADERS extension function.

Troubleshooting policy extensions

September 14, 2021

If your extension function is not behaving as expected, you can use extension tracing functionality to verify the behavior of your extension function. You can also add logging to your extension function by using the custom logging functionality, where you can define the log level to be captured on the Citrix ADC appliance.

This topic provides information on:

- Extension tracing
- Custom logging

Extension tracing

To show what your extension function is doing, extension tracing functionality logs the execution of the function to the Citrix ADC system log (/var/log/ns.log). The trace logging uses the DEBUG log level, which normally is not enabled. Therefore, you have to enable ALL log levels. Then you can enable tracing by setting the -trace option of the set ns extension command. The available settings are:

- off turn off tracing (equivalent to unset ns extension -trace).
- calls trace function calls with arguments and function returns with the first return value.
- lines trace the above plus line numbers for executed lines.
- all trace the above plus local variables changed by executed lines.

Example:

```
set audit syslogParams -loglevel ALL

set ns extension combine_headers -trace all
```

Each trace message has the format

```
log-header : default NSEXTENSION Message message-number 0 : "TRACE
function-name CALL call-number: event"
```

Where,

- log-header supplies timestamps, the Citrix ADC IP address, and the Packet Engine ID.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- message-number is a sequential number identifying the log message.
- function-name is the extension function name.
- call-number is a sequential number for each extension function call. It can be used to group all the trace messages for an extension function call.
- event is one of the following:
  - CALL function-name ; parameter-values indicates that the function has been called with the specified parameters.
  - RETURN FROM function-name ; return = value indicates that a function has returned the specified (first) value. (Additional return values are not reported.)
  - LINE line-number ; variable-values indicates that a line has been executed and lists any variables with changed values.

Where,

- value or values is
  - a number, with or without a decimal point,
  - a string, enclosed in double quotes and with escaped characters as described earlier,
  - a boolean true or false,
  - nil,
  - a table constructor, of the format {[key1]=value1,[key2]=value2, …}.
- parameter-values is parameter1 = value1 ; parameter2 = value2 , …
- variable-values is variable1 = value1 ; variable2 = value2 , …

An example of abbreviated log messages:

```
>shell tail -f /var/log/ns.log | grep TRACE | more

... NSEXTENSION Message 3035 0 : "TRACE combine_headers CALL 30 : CALL

      amd64-portbld-freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3\r
      \nH1: abcd\r\nAccept: */*\r\nHost: 10.217.24.7\r\nH2: h2val1, h2val2
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
        , h2val3\r\n\r\n""
```

Custom logging

You can also add your own logging to your extension function. To do so, use the built-in ns.logger:*level*() function, where *level* is emergency, alert, critical, error, warning, notice, info, or debug. The parameters are the same as the C printf() function: a format string, and a variable number of arguments to supply values for the % specified in the format string. For example, you might add the following to the COMBINE_HEADERS function to log the result of a call:

```
local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"

ns.logger:info("Result: %s", result_str)

return result_str
```

The above function would log the following message to/var/log/ns.log for the sample input shown in the abbreviated log messages examples in the Extension Tracing section above.

```
... : default NSEXTENSION Message 143 0 : "Result: Host: 10.217.24.7:2000^
M H1: abcd, 1234^M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4)
libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3^M Accept: */*^M H2: h2val1,
h2val2, h2val3^M ^M"
```

Optimization

March 28, 2023

The Citrix ADC optimization features reduce transaction times between the clients and the servers, and they reduce bandwidth consumption. They also enhance server performance by offloading some tasks and making others more efficient.

Feature	Description
Client Keep-Alive	Handles multiple requests on a single client connection. The client does not have to negotiate a new connection for each request to the server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Feature	Description
HTTP Compression	Compresses HTTP responses sent from the servers to compression-aware browsers. The smaller responses reduce download time and save bandwidth.
Integrated Caching	Stores responses to client requests. Subsequent requests for the same content are served from the Citrix ADC cache instead of being forwarded to the origin server.
Front End Optimization	Reduces the load and render time of web pages by simplifying and optimizing the content served to the client browser. **Note**: Supported from NetScaler 10.5 onwards.
SPDY (Speedy)	Acts as a SPDY gateway between clients and your servers, providing SPDY support without the need to configure/upgrade SPDY on the servers. **Note**: Supported from NetScaler 10.1 onwards.

Client keep-alive

November 2, 2023

The client keep-alive feature enables multiple clients requests to be sent on a single connection. This feature benefits transaction management. When the Client Keep-Alive mode is enabled on an appliance and the server response to the client request contains the Connection: close the HTTP header and performs the following tasks:

- Renames the existing Connection header name by shuffling the characters in the header name.
- Adds a new Connection: header with Keep-Alive as the value for the header.

The Client Keep-Alive mode enables the Citrix ADC appliance to process multiple requests and responses using the same socket connection. The feature keeps the connection between the client and the appliance (client-side connection) open even after the server closes the connection with the appliance. This allows multiple clients requests using a single connection and saves the round trips associated in opening and closing a connection. Client keep-alive is most beneficial in SSL sessions.

Client keep-alive is useful for the following scenarios:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- If the server does not support the client keep-alive.
- If the server supports but an application on the server does not support the client keep-alive.

> **Note:**
> Client keep-alive is applicable for HTTP and SSL traffic. Client-keep alive can be configured globally to handle all traffic. Also, you can activate it on specific services.

In the client keep-alive environment, the configured services intercept the client traffic and the client request is directed to the origin server. The server sends the response and closes the connection between the server and the appliance. If a "Connection: Close"header is present in the server response, the appliance corrupts this header in the client-side response, and the client-side connection is kept open. As a result, the client does not have to open a new connection for the next request. Instead, the connection to the server is reopened.

> **Note:**
> If a server sends back two "Connection: Close"headers, only one is edited. This results in significant delays on the client rendering of the object because a client does not assume that the object has been delivered completely until the connection is closed.

Configure client keep-alive

Client keep-alive, by default, is disabled on the Citrix ADC, both globally and at service level. Therefore, you must enable the feature at the required scope.

> **Note:**
> If you enable the client keep-alive globally, it is enabled for all services, regardless of whether you enable it at the service level. Also, you must configure some HTTP parameters to specify the following:
>
> - the maximum number of HTTP connections retained in the connection reuse pool.
> - enable connection multiplexing, and enable persistence `Etag`.
>
> **Note:**
> When Persistent `ETag` is enabled, the `ETag` header includes information about the server that served the content. This ensures that cache validation conditional requests or browser requests, for that content, always reaches the same server.

Configure client keep-alive by using Citrix ADC command interface

At the command prompt, do the following:

1. Enable client keep-alive on the Citrix ADC.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- At global level - `enable ns mode cka`
- At service level - `set service <name> -CKA YES`

> **Note:**
>
> Client keep-alive can be enabled only for HTTP and SSL services.

2. Configure HTTP parameters on the HTTP profile that is bound to one or more services.

```
set ns httpProfile <name> -maxReusePool <value> -conMultiplex
    ENABLED -persistentETag ENABLED
```

> **Note:**
>
> Configure these parameters on the `nshttp_default _profile HTTP` profile, to make them available globally.

Configure client keep-alive by using Citrix ADC GUI

1. Enable client keep-alive on the Citrix ADC.
   - At global level

     Navigate to **System** > **Settings**, click **Configure Modes** and select **Client side Keep Alive**.
   - At service level

     Navigate to **Traffic Management** > **Load Balancing** > **Services**, and select the required service. In the **Settings** section, select **Client Keep-Alive** check box.
2. Configure the required HTTP parameters on the HTTP profile that is bound to one or more services.
3. Navigate to **System** > **Profiles**, and on **HTTP Profiles** tab, select the required profile and update the required HTTP parameters.

HTTP compression

February 21, 2023

For websites with compressible content, the HTTP compression feature implements lossless compression to alleviate latency, long download times, and other network-performance problems by compressing the HTTP responses sent from servers to compression-aware browsers. You can improve

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

server performance by offloading the computationally intensive compression task from your servers to the Citrix ADC appliance.

The following table describes the capabilities of the HTTP compression feature:

Functionality	Description
Compression Ratio	Compression ratio depends on the types of files in the responses, but is always significant, noticeably reducing the amount of data transmitted over the network.
Browser Awareness	Citrix ADC serves compressed data to compression aware browsers only, reducing the transaction time between the client and the server. Most modern web browsers support HTTP compression.
Compression blocking	You can define content filters to selectively block compression by applying built-in actions.
Compression Caching	With the integrated caching feature enabled, subsequent requests for the same content are served from the local cache, reducing the number of round trips to the server and improving transaction times.
HTTPS Support	Compression is useful on SSL connections, because it reduces the amount of content that has to be encrypted, either on the server or by the Citrix ADC appliance, and decrypted by the client.
Intelligent Response Filtering	The Citrix ADC compression engine intelligently filters server responses based on defined compression parameters. For example, the compression engine detects zero-content-length responses and compressed responses and does not compress them. The detection of compressed responses enables origin sites to use server-based compression with the Citrix ADC compression feature.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Functionality	Description
Compression Switching	The Citrix ADC appliance transparently directs requests from compression aware clients to compression capable servers, so that responses to those clients are compressed, and responses to other clients are not delayed by compression processing.

How HTTP compression works

A Citrix ADC can compress both static and dynamically generated data. It applies the GZIP or the DEFLATE compression algorithm to remove extraneous and repetitive information from the server responses and represent the original information in a more compact and efficient format. This compressed data is sent to the client's browser and uncompressed as determined by the browser's supported algorithm or algorithms (GZIP or DEFLATE).

Citrix ADC compression treats static and dynamic content differently.

- Static files are compressed only once, and a compressed copy is stored in local memory. Subsequent client requests for cached files are serviced from that memory.
- Dynamic pages are dynamically created each time a client requests them.

When a client sends a request to the server:

1. The client request arrives at the Citrix ADC. The ADC examines the headers and stores information about what kind of compression, if any, the browser supports.
2. The ADC forwards the request to the server and receives the response.
3. The Citrix ADC compression engine examines the server response for compressibility by matching it against policies.
4. If the response matches a policy associated with a compression action, and the client browser supports a compression algorithm specified by the action, the Citrix ADC applies the algorithm and sends the compressed response to the client browser.
5. The client applies the supported compression algorithm to decompress the response.

Configure HTTP compression

By default, compression is disabled on the Citrix ADC. You must enable the feature before configuring it. If the feature is enabled, the ADC compresses server requests specified by compression policies.

To enable HTTP compression by using the CLI

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Compression can be enabled for HTTP and SSL services only. You can enable it globally, so that it applies to all HTTP and SSL services, or you can enable it just for specific services.

At the command prompt, enter one of the following commands to enable compression globally or for a specific service:

- `enable ns feature cmp`
  OR
- `set service \<name\> -CMP YES`

To configure compression by using the GUI

Do one of the following:

To enable compression globally, navigate to System > Settings, click **Configure Basic Features**, and select HTTP Compression.

To enable compression for a specific service, navigate to **Traffic Management > Load Balancing > Services**, select the service, and click Edit. In the Settings group, click the pencil icon and enable Compression.

Configuring a compression action

A compression action specifies the action to take when a request or response matches the rule (expression) in the policy with which the action is associated. For example, you can configure a compression policy that identifies requests that will be sent to a particular server, and associate the policy with an action that compresses the server's response.

There are four built-in compression actions:

- COMPRESS: Uses the GZIP algorithm to compress data from browsers that support either GZIP or both GZIP and DEFLATE. Uses the DEFLATE algorithm to compress data from browsers that support only the DEFLATE algorithm. If the browser does not support either algorithm, the browser's response is not compressed.
- NOCOMPRESS: Does not compress data.
- GZIP: Uses the GZIP algorithm to compress data for browsers that support GZIP compression. If the browser does not support the GZIP algorithm, the browser's response is not compressed.
- DEFLATE: Uses the DEFLATE algorithm to compress data for browsers that support the DEFLATE algorithm. If the browser does not support the DEFLATE algorithm, the browser's response is not compressed. After creating an action, you associate the action with one or more compression policies.

At the command prompt, enter the following command to create a compression action:

```
add cmp action <name> <cmpType> [-addVaryHeader <addVaryHeader> -
varyHeaderValue<string>]
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure a compression policy by using the CLI

A compression policy contains a rule, which is a logical expression that enables the Citrix ADC appliance to identify the traffic that should be compressed.

When the Citrix ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

At the command prompt, enter the following command to create a compression policy:

```
add cmp policy <name> -rule <expression> -resAction <string>
```

To create a compression action by using the GUI

Navigate to **Optimization** > **HTTP Compression** > **Actions** , click **Add** , and create a compression action to specify the type of compression to be performed on the HTTP response.

Configuring a compression policy

A compression policy contains a rule, which is a logical expression that enables the Citrix ADC appliance to identify the traffic that should be compressed.

When the Citrix ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

The following table lists the built-in HTTP compression policies. These policies are activated globally when you enable compression.

Built-in Classic or Default Syntax Policy	Description
ns_nocmp_mozilla_47, ns_adv_nocmp_mozilla_47	Prevents compression of CSS files when a request is sent from a Mozilla 4.7 browser.
ns_cmp_mscss, ns_adv_cmp_mscss	Compresses CSS files when the request is sent from a Microsoft Internet Explorer browser.
ns_cmp_msapp, ns_adv_cmp_msapp	Compresses files that are generated by the following applications: Microsoft Office Word, Microsoft Office Excel, Microsoft Office PowerPoint.
ns_cmp_content_type, ns_adv_cmp_content_type	Compresses data when the response containsContent-Type header and contains text.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Built-in Classic or Default Syntax Policy	Description
ns_nocmp_xml_ie, ns_adv_nocmp_xml_ie	Prevents compression when a request is sent, from a Microsoft Internet Explorer browser and the response contains a Content-Type header and contains text or xml.

Binding a compression policy

To put a compression policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the Citrix ADC, or to a specific virtual server, so that the policy applies only to requests whose destination is the VIP address of that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

To bind a Compression Policy by using the CLI

At the command prompt, enter one of the following commands to bind a compression policy globally or to a specific virtual server:

- `bind cmp global <policyName> [-priority <positive_integer>] [-state (ENABLED|DISABLED)]...`
- `bind lb vserver <vserverName> -policyName <policyName> -type (Request|Response)-priority <positive_integer> )`

Repeat this command for each virtual server to which you want to bind the compression policy.

To bind a compression policy by using the GUI

Do one of the following:

At global level Navigate to **Optimization** > **HTTP Compression** > **Policies**, click **Policy Manager** and bind the required policies by specifying the relevant Bind Point and Connection Type (Request/Response).

At virtual server level

For load balancing virtual server, Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.

For content switching virtual server, Navigate to **Traffic Management > Content Switching > Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.

Set the Global Compression Parameters for Optimal Performance

Many users accept the default values for the global compression parameters, but you might be able to provide more effective compression by customizing these settings.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note**
> After you configure the global compression parameters, you do not have to reboot your appliance. They get applied to the new flows immediately.

The following table describes the compression parameters that you can set on the Citrix ADC.

Compression Parameters	Description
Quantum size	Size, in KB, of the buffer maintained for accumulating server responses. The responses are compressed when the buffer size exceeds this value. For example, if you set the quantum size to 50 KB, the Citrix ADC compresses the buffer's contents when its size becomes larger than 50 KB. Minimum value: 1. Maximum value: 63488. Default: 57344.
Compression level	Level of compression to apply to server responses. Possible values: Best Speed, Best Compression, optimal.
Minimum HTTP response size	Minimum size, in bytes, of an HTTP response that is compressed. Responses smaller than the value specified by this parameter are sent without being compressed.
Bypass compression on CPU usage	Citrix ADC CPU usage, as a percentage, at or above which no compression is done. Default: 100.
Policy Type*	Type of policies used for compression. Possible values: Classic, Default Syntax. Default: Classic.
Allow Server-side compression	Allow servers to send compressed data to the Citrix ADC.
Compress push packet	Upon receipt of a packet with a TCP PUSH flag, compress the accumulated packets immediately, without waiting for the quantum buffer to be filled.
External Cache	Issue a private response directive indicating that the response message is intended for a single user and must not be cached by a shared or proxy cache.

To configure HTTP compression by using the GUI

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Do one of the following:

- To enable compression globally, navigate to **System** > **Settings**, click **Configure Basic Features**, and select **HTTP Compression**.
- To enable compression for a specific service, navigate to **Traffic Management** > **Load Balancing** > **Services**, select the service, and click **Edit**.
- In the **Settings** group, click the pencil icon and enable **Compression**.

To create a compression action by using the GUI

Navigate to **Optimization** > **HTTP Compression** > **Actions** , click **Add** , and create a compression action to specify the type of compression to be performed on the HTTP response

To create a compression policy by using the GUI

Navigate to **Optimization** > **HTTP Compression** > **Policies** , click **Add**, and create a compression policy by specifying the condition and the corresponding action to be run.

Evaluate compression configuration

You can view the compression statistics in the dashboard utility or in an SNMP monitor. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

Optionally, you can also view statistics for a compression policy, including the number of requests that the policy counter increments during the policy based compression.

> **Note**
>
> - For more information about the statistics and charts, see the Dashboard help on the Citrix ADC appliance.
> - For more information about SNMP, see SNMP topic.

To view compression statistics by using the CLI

At the command prompt, enter the following commands to display the compression statistics:

1. To display compression statistics summary.

```
stat cmp
```

> **Note**
> The stat cmp policy command displays statistics for default syntax compression policies only.

2. To display compression policy hits and details

```
show cmp policy \<name\>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. To display detailed compression statistics

```
stat cmp -detail
```

To view compression statistics by using the dashboard:

In the Dashboard utility, you can display the following types of compression statistics:

- Select Compression to display a summary of the compression statistics.
- To display detailed compression statistics by protocol type, click the Details
- To display the rate of requests processed by the compression feature, click the Graphical View tab.

To view compression statistics by using SNMP

You can view the following compression statistics by using the SNMP network management application.

- Number of compression requests (OID: 1.3.6.1.4.1.5951.4.1.1.50.1)
- Number of compressed bytes transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.2)
- Number of compressible bytes received (OID: 1.3.6.1.4.1.5951.4.1.1.50.3)
- Number of compressible packets transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.4)
- Number of compressible packets received (OID: 1.3.6.1.4.1.5951.4.1.1.50.5)
- Ratio of compressible data received and compressed data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.6)
- Ratio of total data received to total data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.7)

To view more compression statistics by using the GUI

1. To display HTTP compression statistics:

Navigate to **Optimization** > **HTTP Compression** and click **Statistics**.

1. To display statistics of a compression policy.

Navigate to **Optimization** > **HTTP Compression** > **Policies** > select the policy, and click **Statistics**.

1. To display statistics of a compression policy label
2. Navigate to **Optimization** > **HTTP Compression** > **Policies** > select a policy label, and click **Statistics**.

Offloading HTTP compression

Performing compression on a server can affect the server's performance. A Citrix ADC placed in front of your web servers and configured for HTTP compression offloads compression of both static and dynamic content, saving server CPU cycles and resources.

You can offload compression from the Web servers in either of two ways:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Disable compression on the web servers, enable the Citrix ADC Compression feature at a global level, and configure services for compression.

Leave the compression feature enabled on the web servers and configure the Citrix ADC appliance to remove the "Accept Encoding"header from all HTTP client requests. The servers then send uncompressed responses. The Citrix ADC compresses the server responses before sending them to the clients.

> **Note**
> The second option does not work if the servers automatically compress all responses. The Citrix ADC does not attempt to compress a response that is already compressed.

The Servercmp parameter enables the Citrix ADC appliance to handle offload HTTP compression. By default, this parameter is set ON for the server to send compressed data to the Citrix ADC appliance. To offload HTTP compression, you need to set the servercmp parameter to OFF. At the command prompt, enter the following commands:

```
set service <service name> -CMP YES
```

Repeat this command for each service for which you want to enable compression.

```
show service <service name>
```

Repeat this command for each service, to verify that compression is enabled.

```
Save config
```

```
set cmp parameter –serverCmp OFF
```

> **Note:**
>
> When the `Servercmp` parameter is turned on and if the appliance receives compressed response from the server, the appliance does not further compress the data. Instead, it forwards the compressed response to the client.

Integrated caching

December 17, 2024

The integrated cache provides in-memory storage on the Citrix ADC appliance and serves Web content to users without requiring a round trip to an origin server. For static content, the integrated cache requires little initial setup. After you enable the integrated cache feature and perform basic setup (for example, determining the amount of Citrix ADC appliance memory the cache is permitted to use), the integrated cache uses built-in policies to store and serve specific types of static content,

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

including simple webpages and image files. You can also configure the integrated cache to store and serve dynamic content that is marked as non-cacheable by Web and application servers (for example, database records and stock quotes).

> **Note:**
>
> The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

When a request or response matches the rule (logical expression) specified in a built-in policy or a policy that you have created, the NetScaler appliance performs the action associated with the policy. By default, all policies cache objects in and retrieve them from the default content group. However, you have the option to create custom content groups for different types of content.

To enable the appliance to find cached objects in a content group, you can configure selectors. The selectors match cached objects against expressions, or you can specify parameters for finding objects in the content group. If you use selectors as recommended by Citrix, configure them first, so that you can specify selectors when you configure content groups. Next, set up any content groups that you want to add, so that they are available when you configure the policies. To complete the initial configuration, create policy banks by binding each policy to a global bind point or a virtual server. Or, you can bind a label that can be called from other policy banks.

Integrated caching can be improved using pre-loading cached object method before they are scheduled to expire. To manage the handling of cached data, you can configure caching-related headers inserted into the responses. The integrated cache can also act as a forward proxy for other cache servers.

> **Note:**
>
> Integrated caching requires some familiarity with HTTP requests and responses. For more information, see HTTP headers.

How integrated cache works

The integrated cache monitors HTTP and SQL requests that flow through the Citrix ADC appliance and compares the requests with stored policies. Depending on the outcome, the integrated cache feature either searches the cache for the response or forwards the request to the origin server. For HTTP requests, integrated caching serves as partial content from the cache in response to single byte-range and multi-part byte-range requests.

Cached data is compressed if the client accepts compressed content. You can configure expiration times for a content group, and you can selectively expire entries in a content group.

Data that is served from the integrated cache is a hit, and data served from the origin is a cache miss, as described in the following table.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Transaction Type	Specification
Cache Hit	Responses that the Citrix ADC appliance serves from the cache, including: Static objects, for example, image files and static webpages, 200 OK pages, 203 Non-Authoritative Response pages, 300 Multiple Choices pages, 301 Moved Permanently pages, 302 Found pages, 304 Not Modified pages, These responses are known as positive responses. The Citrix ADC appliance also caches the following negative responses: 307 Temporary Redirect pages, 403 Forbidden pages, 404 Not Found pages, 410 Gone pages. To further improve performance, you can configure the Citrix ADC appliance to cache more types of content.
Storable Cache Miss	For a storable cache miss, the Citrix ADC appliance fetches the response from the origin server, and stores the response in the cache before serving it to the client.
Non-Storable Cache Miss	A non-storable cache miss is inappropriate for caching. By default, any response that contains the following status codes is a non-storable cache miss: 201, 202, 204, 205, 206 status codes, All 4xx codes, except 403, 404 and 410, 5xx status codes

> **Note:**
>
> To integrate dynamic caching with your application infrastructure, use the NITRO API to issue cache commands remotely. For example, you can configure triggers that expire cached responses when a database table is updated.

To ensure the synchronization of cached responses with the data on the origin server, you configure expiration methods. When the Citrix ADC appliance receives a request that matches an expired response, it refreshes the response from the origin server.

> **Note:**
>
> Citrix recommends that you synchronize the times on the Citrix ADC appliance and one or more back-end servers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

How dynamic cache works

Dynamic caching evaluates HTTP requests and responses based on parameter-value pairs, strings, string patterns, or other data. For example, suppose that a user searches for Bug 31231 in a bug reporting application. The browser sends the following request on the user's behalf:

```
GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&
    Template=view&TableId=1000

Host: mycompany.net

User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9)
     Gecko/2008052906 Firefox/3.0

Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q
    =0.8

Accept-Language: en-us,en;q=0.5
```

In this example, GET requests for this bug reporting application always contain the following parameters:

- IssuePage
- RecordID
- Template
- TableId

GET requests do not update or alter the data, so you can configure these parameters in caching policies and selectors, as follows:

- You configure a caching policy that looks for the string mybugreportingsystem and the GET method in HTTP requests. This policy directs matching requests to a content group for bugs.
- In the content group for bugs, you configure a `hit` selector that matches various parameter-value pairs, including IssuePage, RecordID, and so on.

> **Note**
>
> A browser can send multiple GET requests based on one user action. The following is a series of three separate GET requests that a browser issues when a user searches for a bug based on a bug ID.

```
GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&
    Template=view&TableId=1000

GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=
    viewbtns&RecordId=31231&TableId=1000

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
5     GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=
          viewbody&RecordId=31231&tableid=1000
```

To fulfill these requests, multiple responses are sent to the user's browser, and the webpage that the user sees is an assembly of the responses.

If a user updates a bug report, the corresponding responses in the cache must be refreshed with data from the origin server. The bug reporting application issues HTTP POST requests when a user updates a bug report. In this example, you configure the following to ensure that POST requests trigger invalidation in the cache:

- A request-time invalidation policy that looks for the string mybugreportingsystem and the POST HTTP request method, and directs matching requests to the content group for bug reports.
- An invalidation selector for the content group for bug reports that expires cached content based on the RecordID parameter. This parameter appears in all the responses, so the invalidation selector can expire all relevant items in the cache.

The following excerpt shows a POST request that updates the sample bug report.

```
1     POST /mybugreportingsystem/mybugreport.dll?TransitionForm HTTP/1.1\
          r\n
2
3     User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.0)
          Opera 7.23 [en]\r\n
4
5     Host: mybugreportingsystem\r\n
6

          issues+in+HTTP&F43. . .
```

When the Citrix ADC appliance receives this request, it does the following:

- Matches the request with an invalidation policy.
- Finds the content group that is named in the policy.
- Applies the invalidation selector for this content group and expires all responses that match RecordID=31231.

When a user issues a new request for this bug report, the Citrix ADC appliance goes to the origin server for updated copies of all the responses that are associated with the report instance. It stores the re-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

sponses in the content group, and serves them to the user's browser, which reassembles the report and displays it.

Configure integrated cache

To use the integrated cache, you must install the license and enable the feature. After you enable the integrated cache, the Citrix ADC® appliance automatically caches static objects as specified by built-in policies and generates statistics on cache behavior. (Built-in policies have an underscore in the initial position of the policy name.)

Even if the built-in policies are adequate for your situation, you might want to modify the global attributes. For example, you might want to modify the amount of Citrix ADC appliance memory allocated to the integrated cache.

If you would like to observe cache operation before changing settings, see "Displaying Cached Objects and Cache Statistics."

> **Note:**
>
> The Citrix ADC cache is an in-memory store that is purged when you restart the appliance.

To install integrated cache license

- An integrated cache license is required.
- Obtain a license code from Citrix, go to the command line interface, and log in.

At the command line interface, copy the license file to the `/nsconfig/license` folder.

- Reboot the Citrix ADC appliance by using the following command:

```
reboot
```

To enable integrated caching:
When you enable integrated caching, the Citrix ADC appliance begins caching server responses. If you have not configured any policies or content groups, the built-in policies store cached objects in the Default content group.

At the command prompt, type one of the following commands to enable or disable integrated caching:

```
enable ns feature IC
```

Configure global attributes for caching

Global attributes apply to all cached data. You can specify the amount of Citrix ADC memory allocated to the integrated cache, Via header insertion. A criterion for verifying that a cached object must

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

be served. The maximum length of a POST body permitted in the cache, whether to bypass policy evaluation for HTTP GET requests, and an action to take when a policy cannot be evaluated.

The cache memory capacity is limited only by the memory of the hardware appliance. Also, any packet engine (central distribution hub of all incoming TCP requests) in the nCore Citrix ADC appliance is aware of objects cached by other packet engines in the nCore Citrix ADC appliance.

> **Note:**
>
> When the default global memory limit is set as 0 and the Integrated Caching (IC) feature is enabled, the appliance does not cache any objects. For caching, you must explicitly configure the global memory limit. However, if you enable "set authentication, authorization, and auditing parameter enableStaticPageCaching"option, there will be some default memory configured in the appliance. This memory is insufficient for caching large Objects and so it is necessary to assign a higher memory limit for IC. You can perform this by configuring the "set cache parameter –memLimit"command. The new setting is applied only after you save the configuration and reboot the appliance.

You can modify the global memory limit configured for caching objects. However, when you update the global memory limit to a value lower than the existing value (for example, from 10 GB to 4 GB), the appliance continues to use the memory limit.

It means that even though the integrated caching limit is configured to some value, the actual limit used can be higher. This excessive memory is however released when the objects are removed from cache.

The output of the show cache parameter command indicates the configured value (memory Usage limit) and the actual value being used (memory usage limit (active value)).

At the command prompt, type:

```
set cache parameter [-memLimit <MBytes>] [-via <string>] [-
   verifyUsing <criterion>] [-maxPostLen <positiveInteger>] [-
   prefetchMaxPending <positiveInteger>] [-enableBypass(YES|NO)] [-
   undefAction (NOCACHE|RESET)]
```

Enable integrated caching by Citrix ADC GUI

Navigate to **System** > **Settings**, click **Configure Basic Features**, and select **Integrated Caching**.

Configure global settings for caching by using the Citrix ADC GUI

Navigate to **Optimization** > **Integrated Caching**, click **Change Cache Settings**, and configure the global settings for caching.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Set up built-in content group, pattern set, and policies for Integrated Cache

The Citrix ADC appliance includes a built-in integrated caching configuration that you can use for caching content. The configuration consists of a content group called ctx_cg_poc, a pattern set called ctx_file_extensions, and a set of integrated cache policies. In the content group ctx_cg_poc, only objects that are 500 KB or smaller are cached. The content is cached for 86000 seconds, and the memory limit for the content group is 512 MB. The pattern set is an indexed array of common extensions for file-type matching.

The following table lists the built-in integrated caching policies. By default, the policies are not bound to any bind point. You must bind the policies to a bind point if you want the Citrix ADC appliance to evaluate traffic against the policies. The policies cache objects in the ctx_cg_poc content group.

Integrated caching policy name	Policy rule
_cacheVPNStaticObjects	HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).CONTAINS_IN “ctx_file_extensions”).BETWEEN(101,150)
_cacheTCPVPNStaticObjects	HTTP.REQ.URL.ENDSWITH(“.css”)
_cacheOCVPNStaticObjects	HTTP.REQ.URL.ENDSWITH(“.pdf”)
_cacheWFStaticObjects	HTTP.REQ.URL.ENDSWITH(“.js”)
_mayNoCacheReq	HTTP.RES.HEADER(“Content-Type”).CONTAINS(“application/x-javascript”)
_noCacheRest	TRUE

Flush cache configuration

You can flush a cache group, cache groups, or cache object locator. Following are the commands to flush cache objects.

At the command prompt, type:

```
flush cache contentgroup all
```

Example

```
1          0x00000089bae000000004 DEFAULT GET  //1.1.1.1:80/html/index.
               html?name=hello
2          0x00000089bae000000005 DEFAULT GET  //1.1.1.1:80/html/index.
               html?name=hi
3
4          Flush cache contentGroup all
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
5          done
6
7  `flush cache contentgroup <content group name>`
```

Example:

```
1          0x00000089bae000000004 DEFAULT GET  //1.1.1.1:80/html/index.
               html?name=hello
2          0x00000089bae000000005 DEFAULT GET  //1.1.1.1:80/html/index.
               html?name=hi
3
4          Flush cache ob -| 0x00000089bae000000004
5          done
6
7  `flush cache object (-locator <positive_integer> | (-url <URL> (-host <
       string> [-port <port>] [-groupName <string>] [-httpMethod ( GET |
       POST )])))`
```

Example:

```
1          0x00000089bae000000006 DEFAULT GET //1.1.1.1:80/html/index.html
2
3          flush cache ob -URL /html/index.html -host 1.1.1.1 -groupName
               DEFAULT
4          done
```

Flush cache configuration by using the Citrix ADC GUI

Complete the steps to configure cache flushing using the Citrix ADC GUI

1. Navigate to **Optimization** > **Content Groups**.
2. In the **Content Groups** detailed pane, click **Add**.
3. In the **Create Cache Content Groups** page, set the following parameter under **Others** tab:

    a) Flush Cache. Select the check box to flush the cache object.

4. Click **Create** and **Close**.

Configure integrated caching for various scenarios

The following section describes the configuration of integrated caching on NetScaler appliance for various scenarios.

Starting from NetScaler 9.2 release, the integrated caching has more memory for caching. The integrated caching memory is only limited by the memory available on the hardware appliance. You can allocate up to 50 percent of the available memory to the integrated caching feature.

To set the memory allocation for the cache by using the CLI

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

At the command prompt, type:

```
set cache parameter -memlimit <value>
```

> **Note:**
>
> The default global memory limit for integrated caching is zero. Therefore, even if you enable the integrated caching feature, the NetScaler appliance does not cache any objects until the global memory limit is explicitly set.

The following section instructs you to configure integrated caching on different scenarios.

> **Note:**
>
> The memory limit of the NetScaler appliance is identified when the appliance starts. Therefore, any changes to the memory limit require you to restart the appliance to make the changes applicable across the packet engines.

Integrated caching is enabled and cache memory limit is set to non-zero

Consider a scenario, where you start the appliance, the integrated caching feature is enabled and the global memory limit is set to a positive number. The memory you had set earlier is allocated to the integrated caching feature during the boot process. You might want to change the memory limit to another value depending on the available memory on the appliance.

Configuring by using the CLI

1. Display the cache parameter

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 500 MBytes
4                  Memory usage limit (active value): 500 MBytes
5                  Maximum value for Memory usage limit: 843 MBytes
6                  Via header: NS-CACHE-9.3: 18
7                  Verify cached object using: HOSTNAME_AND_IP
8                  Max POST body size to accumulate: 0 bytes
9                  Current outstanding prefetches: 0
10                 Max outstanding prefetches: 4294967295
11                 Treat NOCACHE policies as BYPASS policies: YES
12                 Global Undef Action: NOCACHE
```

1. Set a non-zero memory limit

```
set cache parameter -memlimit 600
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:**
>
> The preceding command displays the following warning message: **Warning: To use a new Integrated Cache memory limit, save the configuration and restart the NetScaler appliance.**

1. Save the configuration

```
save config
```

1. From the shell prompt, run the following command to verify in the configuration file.

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 600 -via NS-CACHE-9.3: 18 -verifyUsing
HOSTNAME_AND_IP -maxPostLen 0 -enableBypass YES -undefAction NOCACHE
```

1. Reboot the appliance

```
root@ns# reboot
```

1. Verify the new value for the memory limit

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 600 MBytes
4                  Memory usage limit (active value): 600 MBytes
5                  Maximum value for Memory usage limit: 843 MBytes
6                  Via header: NS-CACHE-9.3: 18
7                  Verify cached object using: HOSTNAME_AND_IP
8                  Max POST body size to accumulate: 0 bytes
9                  Current outstanding prefetches: 0
10                 Max outstanding prefetches: 4294967295
11                 Treat NOCACHE policies as BYPASS policies: YES
12                 Global Undef Action: NOCACHE
```

After all packet engines start successfully, the integrated caching feature negotiates the memory you had configured. If the appliance cannot use the configured memory, then the memory is allocated accordingly. If the available memory is less than the one you allocated, the appliance recommends a lesser number. The integrated caching feature uses same as the active value.

Integrated caching is disabled and cache memory limit is set to non-zero

In this scenario, when you start the appliance, the integrated caching feature is disabled and the global memory limit is set to a positive number. Therefore, no memory is allocated to the integrated caching during the boot process.

Configuring by using the CLI

1. Display the cache parameter

```
> show cache parameter
        Integrated cache global configuration:
        Memory usage limit: 600 MBytes
        Maximum value for Memory usage limit: 843 MBytes
        Via header: NS-CACHE-9.3: 18
        Verify cached object using: HOSTNAME_AND_IP
        Max POST body size to accumulate: 0 bytes
        Current outstanding prefetches: 0
        Max outstanding prefetches: 4294967295
        Treat NOCACHE policies as BYPASS policies: YES
        Global Undef Action: NOCACHE
```

1. Set a new memory limit

```
set cache parameter -memlimit 500
```

> **Note:**
>
> The preceding command displays the following warning message: **Warning: Feature not enabled [IC]**.

1. Save the configuration

```
save config
```

1. From the shell prompt, run the following command to verify in the configuration file

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 500 -via NS-CACHE-9.3: 18 -verifyUsing
HOSTNAME_AND_IP -maxPostLen 0 -enableBypass YES -undefAction NOCACHE
```

1. Verify the new value for the memory limit

```
> show cache parameter
        Integrated cache global configuration:
        Memory usage limit: 500 MBytes
        Maximum value for Memory usage limit: 843 MBytes
        Via header: NS-CACHE-9.3: 18
        Verify cached object using: HOSTNAME_AND_IP
        Max POST body size to accumulate: 0 bytes
        Current outstanding prefetches: 0
        Max outstanding prefetches: 4294967295
        Treat NOCACHE policies as BYPASS policies: YES
        Global Undef Action: NOCACHE
```

1. Enable the integrated caching feature

```
enable ns feature IC
```

1. Verify the new value for the memory limit

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 500 Mbytes
4                  Memory usage limit (active value): 500 Mbytes
5                  Maximum value for Memory usage limit: 843 MBytes
6                  Via header: NS-CACHE-9.3: 18
7                  Verify cached object using: HOSTNAME_AND_IP
8                  Max POST body size to accumulate: 0 bytes
9                  Current outstanding prefetches: 0
10                 Max outstanding prefetches: 4294967295
11                 Treat NOCACHE policies as BYPASS policies: YES
12                 Global Undef Action: NOCACHE
```

> **Note:**
>
> 500 MB of memory is allocated to the integrated caching feature.

1. Save the configuration to ensure that the memory is automatically allocated to the feature when the appliance is restarted.

Integrated caching is enabled and cache memory is set to zero

In this scenario, when you start the appliance, the integrated caching feature is enabled and the global memory limit is set to zero. Therefore, no memory is allocated to the integrated caching during the boot process.

Configuring by using the CLI

1. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns# cat ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 0 -via NS-CACHE-9.3: 18 -verifyUsing
 HOSTNAME_AND_IP -maxPostLen 4096 -enableBypass YES -undefAction
NOCACHE
```

1. Verify the value for the memory limit

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> show cache parameter
        Integrated cache global configuration:
        Memory usage limit: 0 Mbytes
        Maximum value for Memory usage limit: 843 MBytes
        Via header: NS-CACHE-9.3: 18
        Verify cached object using: HOSTNAME_AND_IP
        Max POST body size to accumulate: 0 bytes
        Current outstanding prefetches: 0
        Max outstanding prefetches: 4294967295
        Treat NOCACHE policies as BYPASS policies: YES
        Global Undef Action: NOCACHE
```

> **Note:**
>
> The memory limit is set to 0 MB and no memory is allocated to the integrated caching feature.

1. Set the memory limits to ensure the integrated caching feature caches objects

```
set cache parameter -memLimit 600
```

Once you run the preceding command, the appliance negotiates memory for the integrated caching feature and the available memory is assigned to the feature. It results in appliance caching objects without restarting the appliance.

1. Verify the value for the memory limit

```
> show cache parameter
        Integrated cache global configuration:
        Memory usage limit: 600 Mbytes
        Memory usage limit (active value): 600 Mbytes
        Maximum value for Memory usage limit: 843 MBytes
        Via header: NS-CACHE-9.3:
        Verify cached object using: HOSTNAME_AND_IP
        Max POST body size to accumulate: 0 bytes
        Current outstanding prefetches: 0
        Max outstanding prefetches: 4294967295
        Treat NOCACHE policies as BYPASS policies: YES
        Global Undef Action: NOCACHE
```

> **Note:**
>
> 600 MB of memory is allocated to the integrated caching feature.

1. Save the configuration. Ensure that the memory is automatically allocated to the feature when the appliance is restarted.
2. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set cache parameter -memLimit 600 -via NS-CACHE-9.3: -verifyUsing
 HOSTNAME_AND_IP -maxPostLen 4096 -enableBypass YES -undefAction
NOCACHE
```

Integrated caching is disabled and cache memory is set to zero

In this scenario, when you start the appliance, the integrated caching feature is disabled and the global memory limit is set to zero. Therefore, no memory is allocated to the integrated caching during the boot process.

Configuring by using the CLI

1. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 0 -via NS-CACHE-9.3: 18 -verifyUsing
 HOSTNAME_AND_IP -maxPostLen 4096 -enableBypass YES -undefAction
NOCACHE
```

1. Verify the value for the memory limit

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 0 Mbytes
4                  Maximum value for Memory usage limit: 843 MBytes
5                  Via header: NS-CACHE-9.3: 18
6                  Verify cached object using: HOSTNAME_AND_IP
7                  Max POST body size to accumulate: 0 bytes
8                  Current outstanding prefetches: 0
9                  Max outstanding prefetches: 4294967295
10                 Treat NOCACHE policies as BYPASS policies: YES
11                 Global Undef Action: NOCACHE
```

> **Note:**
>
> The memory limit is set to 0 MB and no memory is allocated to the integrated caching feature. Also, when you run any cache configuration command, the following warning message is displayed: **Warning: Feature not enabled [IC]**.

1. Enable the integrated caching feature

```
enable ns feature IC
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:**
>
> At this stage, when you enable the integrated caching feature, the appliance does not allocate memory to the feature. As a result, no object is cached to the memory. Also, when you run any cache configuration command, the following warning message is displayed: **No memory is configured for IC. Use set cache parameter command to set the memory limit.**

1. Set the memory limits to ensure the integrated caching feature caches objects

```
set cache parameter -memLimit 500
```

Once you run the preceding command, the appliance negotiates memory for the integrated caching feature and the available memory is assigned to the feature. It results in the appliance caching objects without restarting the appliance.

> **Note:**
>
> The order in which you enable the feature and set the memory limits is important. If you set the memory limits before enabling the feature, then the following warning message is displayed: **Warning: Feature not enabled [IC]**.

1. Verify the value for the memory limit

```
1          > show cache parameter
2                  Integrated cache global configuration:
3                  Memory usage limit: 500 Mbytes
4                  Memory usage limit (active value): 500 Mbytes
5                  Maximum value for Memory usage limit: 843 MBytes
6                  Via header: NS-CACHE-9.3:
7                  Verify cached object using: HOSTNAME_AND_IP
8                  Max POST body size to accumulate: 0 bytes
9                  Current outstanding prefetches: 0
10                 Max outstanding prefetches: 4294967295
11                 Treat NOCACHE policies as BYPASS policies: YES
12                 Global Undef Action: NOCACHE
```

> **Note:**
>
> 500 MB of memory is allocated to the integrated caching feature.

1. Save the configuration

```
save config
```

NOCACHE
```

Configure selectors and basic content groups

September 14, 2021

You can configure selectors and apply them to content groups. When you add a selector to one or more content groups, you specify whether the selector is to be used for identifying cache requests or identifying cached objects to be invalidated (expired). Selectors are optional. Alternatively, you can configure content groups to use `hit` parameters and invalidation parameters. However, Citrix recommends that you configure selectors.

After configuring selectors, or deciding to use parameters instead, you are ready to set up a basic content group. After creating the basic content group, you need to decide how objects should be expired from the cache, and configure cache expiration. You can further modify the cache as described in Improving Cache Performance and Configuring Cookies, Headers, and Polling, but you might first want to configure caching policies.

> **Note**
>
> Content group parameters and selectors are used only at request time, and you typically associate them with policies that use MAY_CACHE or MAY_NOCACHE actions.

Advantages of selectors

A selector is a filter that locates particular objects in a content group. If you do not configure a selector, the Citrix® ADC appliance looks for an exact match in the content group. This can lead to multiple copies of the same object residing in a content group. For example, a content group that does not have a selector may need to store URLs for host1.domain.com\mypage.htm, host2.domain.com\mypage.htm, and host3.domain.com\mypage.htm. In contrast, a selector can match just the URL (mypage.html, using the expression http.req.url) and the domain (.com, using the expression http.req.hostname.domain), allowing the requests to be satisfied by the same URL.

Selector expressions can perform simple matching of parameters (for example, to find objects that match a few query string parameters and their values). A selector expression can use Boolean logic, arithmetic operations, and combinations of attributes to identify objects (for example, segments of a URL stem, a query string, a string in a POST request body, a string in an HTTP header, a cookie). Selectors can also perform programmatic functions to analyze information in a request. For example,

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

a selector can extract text in a POST body, convert the text into a list, and extract a specific item from the list.

For more information about expressions and what you can specify in an expression, see Policies and Expressions.

Use parameters Instead of selectors

Although Citrix recommends the use of selectors with a content group, you can instead configure `hit` parameters and invalidation parameters. For example, suppose that you configure three `hit` parameters in a content group for bug reports: BugID, Issuer, and Assignee. If a request contains BugID=456, with Issuer=RohitV and Assignee=Robert, the Citrix ADC appliance can serve responses that match these parameter-value pairs.

Invalidation parameters in a content group expire cached entries. For example, suppose that BugID is an invalidation parameter and a user issues a POST request to update a bug report. An invalidation policy directs the request to this content group, and the invalidation parameter for the content group expires all cached responses that match the BugID value. (The next time a user issues a GET request for this report, a caching policy can enable the Citrix ADC appliance to refresh the cached entry for the report from the origin server.)

Note that the same parameter can be used as a `hit` parameter or an invalidation parameter.

Content groups extract request parameters in the following order:

- URL query
- POST body
- Cookie header

After the first occurrence of a parameter, regardless of where it occurred in the request, all its subsequent occurrences are ignored. For example, if a parameter exists both in the URL query and in the POST body, only the one in the URL query is considered.

If you decide to use hit and invalidation parameters for a content group, configure the parameters when you configure the content group.

Note: Citrix recommends that you use selectors rather than parameterized content groups, because selectors are more flexible and can be adapted to more types of data.

Configure a selector

A content group can use a hit selector to retrieve cache hits or use an invalidation selector to expired cached objects and fetch new ones from the origin server.

A selector contains a name and a logical expression, called an *advanced expression*.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For more information about advanced expressions, see Policies and Expressions.

To configure a selector, you assign it a name and enter one or more expressions. As a best practice, a selector expression should include the URL stem and host, unless there is a strong reason to omit them.

To configure a selector by using the CLI

At the command prompt, type:

```
add cache selector \<selectorName\> ( \<rule\> ... )
```

For information about configuring the expression or expressions, see To configure a selector expression by using the command line interface.

```
1 >add cache selector product_selector "http.req.url.query.value(\"
     ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url
     .query.value(\"depotLocation\")"
2
3 > add cache selector batch_selector "http.req.url.query.value(\"
     ProductId\")" "http.req.url.query.value(\"BatchId\")" "http.req.url.
     query.value(\"depotLocation\")"
4
5 > add cache selector product_id_selector "http.req.url.query.value(\"
     ProductId\")"
6
7 > add cache selector batchnum_selector "http.req.url.query.value(\"
     BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
8
9 > add cache selector batchid_selector "http.req.url.query.value(\"
     depotLocation\")" "http.req.url.query.value(\"BatchId\")"
```

To configure a selector by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Selectors**, and add the cache selector.

Content groups

A content group is a container for cached objects that can be served in a response. When you first enable the integrated cache, cacheable objects are stored in a content group named Default. You can create content groups that have unique properties. For example, you can define separate content groups for image data, bug reports, and stock quotes, and you can configure the stock quote content group to be refreshed more often than the other groups.

You can configure expiration of an entire content group or selected entries in a content group.

The data in a content group can be static or dynamic, as follows:

- **Static content groups**. Finds an exact match between the URL stem and host name on the request and the URL stem and host name of the response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Dynamic content groups**. Looks for objects that contain particular parameter-value pairs, arbitrary strings, or string patterns. Dynamic content groups are useful when caching data that is updated frequently (for example, a bug report or a stock quote).

Serve a request from a content group

1. A user enters search criteria for an item, such as a bug report, and clicks the Find button in an HTML form.
2. The browser issues one or more HTTP GET requests. These requests contain parameters (for example, the bug owner, bug ID, and so on).
3. When the Citrix ADC appliance receives the requests, it searches for a matching policy, and if it finds a caching policy that matches these requests, it directs the requests to a content group.
4. The content group looks for appropriate objects in the content group, based on criteria that you configure in a selector.

For example, the content group can retrieve responses that match `NameField=username and BugID=ID`.

1. If it finds matching objects, the Citrix ADC appliance can serve them to the user's browser, where they are assembled into a complete response (for example, a bug report).

Invalidate an object in a content group

1. A user modifies data (for example, the user modifies the bug report and clicks the Submit button).
2. The browser sends this data in the form of one or more HTTP requests. For example, it can send a bug report in the form of several HTTP POST requests that contain information about the bug owner and bug ID.
3. The Citrix ADC appliance matches the requests against invalidation policies. Typically, these policies are configured to detect the HTTP POST method.
4. If the request matches an invalidation policy, the Citrix ADC appliance searches the content group that is associated with this policy, and expires responses that match the configured criteria for invalidation.

For example, an invalidation selector can find responses that match `NameField=username and BugID=ID`.

1. The next time the Citrix ADC appliance receives a GET request for these responses, it fetches refreshed versions from the origin server, caches the refreshed responses, and serves these responses to the user's browser, where they are assembled into a complete bug report.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Set up a basic content group

By default, all cached data is stored in the default content group. You can configure more content groups and specify these content groups in one or more policies.

You can configure content groups for static content, and you must configure content groups for dynamic content. You can modify the configuration of any content group, including the default group.

To set up a basic content group by using the command line interface

At the command prompt, type:

```
add cache contentgroup <name> (-hitSelector <hitSelectorName> -
invalSelector <invalidationSelectorName> | -hitParams <hitParamName>
-invalParams<invalidationParamName>)-type <type> [-relExpiry <sec> |
-relExpiryMilliSec <msec>] [-heurExpiryParam <positiveInteger>]
```

```
add cache contentgroup Products_Details –hitSelector product_selector
 –invalSelector id_selector
```

```
add cache contentgroup bugrep -hitParams IssuePage RecordID Template
TableId -invalParams RecordID -relExpiry 864000
```

To set up a basic content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and create the content group.

Expire or flush cached objects

If a response does not have an Expires header or a Cache-Control header with an expiration time (Max-Age or Smax-Age), you must expire objects in a content group by using one of the following methods:

- Configure content group expiration settings to determine whether and how long to keep the object.
- Configure an invalidation policy and action for the content group. For more information, see Configuring Policies for Caching and Invalidation.
- Expire the content group or objects within it manually.

After a cached response expires, the Citrix ADC appliance refreshes it the next time the client issues a request for the response. By default, when the cache is full, the Citrix ADC appliance replaces the least recently used response first.

The following list describes methods for expiring cached responses using settings for a content group. Typically, these methods are specified as a percent or in seconds:

- **Manual**. Manually invalidate all responses in a content group or all responses in the cache.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Response-based**. Specific expiration intervals for positive and negative responses. Response-based expiry is considered only if the Last-Modified header is missing in the response.
- **Heuristic expiry**. For responses that have a Last-Modified header, the heuristic expiry specifies the mount of time taken from when the response was modified (calculated as the current time minus the Last-Modified time, multiplied by the heuristic expiry value). For example, if a Last-Modified header indicates that a response was updated 2 hours ago, and the heuristic expiry setting is 10%, cached objects expire after 0.2 hours. This method assumes that frequently updated responses must be expired more often.
- **Absolute or relative**. Specify an exact (absolute) time when the response expires every day, in HH:MM format, local time, or GMT. Local time may not work in all time zones.

Relative expiration specifies some seconds or milliseconds from the time a cache miss causes a trip to the origin server to the expiration of the response. If you specify relative expiration in milliseconds, enter a multiple of 10. This form of expiration works for all positive responses. Last-Modified, Expires, and Cache-Control headers in the response are ignored.

Absolute and relative expiration overrides any expiration information in the response itself.

- **On download**. The option Expire After Complete Response Received expires a response when it is downloaded. This is useful for frequently updated responses, for example, stock quotes. By default, this option is disabled.

Enabling both Flash Cache and Expire After Complete Response Received accelerates the performance of dynamic applications. When you enable both options, the Citrix ADC appliance fetches only one response for a block of simultaneous requests.

- **Pinned**. By default, when the cache is full the Citrix ADC appliance replaces the least recently used response first. The Citrix ADC appliance does not apply this behavior to content groups that are marked as pinned.

If you do not configure expiration settings for a content group, the following are more options for expiring objects in the group:

- Configure a policy with an INVAL action that applies to the content group.
- Enter the names of content groups when configuring a policy that uses an INVAL action.

How expiration methods are applied

Expiration works differently for positive and negative responses. Positive and negative responses are described in the table, *Expiration of Positive, and Negative Responses* mentioned below.

The following are rules of thumb for understanding the expiration method that is applied to a content group:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- You can control whether the Citrix ADC appliance evaluates response headers when deciding whether to expire an object.
- Absolute and relative expiration causes the Citrix ADC appliance to ignore the response headers (they override any expiration information in the response).
- Heuristic expiration settings and "Weak Positive"and "Weak Negative"expiration (labeled as **Default** values in the configuration utility) cause the Citrix ADC appliance to examine the response headers. These settings work together as follows:
  - The value in an Expires or Cache-Control header overrides these content group settings.
  - For positive responses that lack an Expires or Cache-Control header but have a Last-Modified header, the Citrix ADC appliance compares heuristic expiration settings with the header value.
  - For positive responses that lack an Expires, Cache-Control, or Last-Modified header, the Citrix ADC appliance uses the "weak positive"value.
  - For negative responses that lack an Expires or Cache-Control header, the Citrix ADC appliance uses the "weak negative"value.

The following table describes how these methods are applied.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Positive	Any header	Expire Content After (relExpiry) with no other settings	Use the value of the **Expire Content After** setting.
Positive	Any header	Expire Content At (absExpiry) with no other settings	Subtract current date from the value of the **Expire Content At** setting.
Positive	Any header	Expire Content After (relExpiry) and Expire content at (absExpiry)	Use the smaller of the two values for the content group settings. See the previous rows in this table.
Positive	Last-Modified (with any other headers)	Heuristic (heurExpiry Param) with any other setting	Subtract the Last-Modified date from the current date, multiply the result by the value of the heuristic expiry setting, and then divide by 100.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Positive	Last-Modified (with any other headers)	Default (positive) (weakPosRel Expiry) and no other setting	Use the value of the Default (positive) expiry setting.
Positive	Expires or Cache-Control: Max-Age header is present	Last-Modified header is absent, Heuristic (heurExpiry Param), Default (positive) (weakPosRel Expiry), or both	Subtract the current date from the Expires or the `Cache-Control:Max-Age` date.
Positive	no caching headers	Default (positive) (weakPosRel Expiry) and any other expiration setting	Use the value of the Default (positive) setting.
Positive	no caching headers	Heuristic (heurExpiry Param) is present, Default (positive) (weakPosRel Expiry) setting is absent.	If the Last-Modified header is absent, the response is not cached or it is cached with an Already Expired status. If the Last-Modified header is present, use the heuristic expiry value.
Negative	Expires or `Cache-Control:Max-Age`	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Subtract the current date from the value of the Expires header, or use the value of the Cache-Control:Max-Age header.
Negative	Expires or Cache-Control headers are absent	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Response is not cached, or is cached with an Already Expired status.
Negative	Expires or `Cache-Control:Max-Age`	Any setting	Subtract the current date from the Expires or `Cache-Control:Max-Age` date.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Negative	Expires and Cache-Control:Max-Age headers are absent	Default (negative) (weakNegRel Expiry)	Use the value of the Default (negative) setting.
Negative	Expires and Cache-Control:Max-Age headers are absent	Any setting other than Default (negative) (weakNegRel Expiry)	Object is not cached or is cached with an Already Expired status.

Expire a content group by manual method

You can manually expire all of the entries in a content group.

To manually expire all responses in a content group by using the command line interface

At the command prompt, type:

```
expire cache contentGroup <name>
```

To manually expire all responses in a content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, select the content group, and click Invalidate to expire all the responses in a content group.

To manually expire all responses in the cache by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and click Invalidate All to expire all the responses in cache.

Configure periodic expiration of a content group

You can configure a content group so that it performs selective or full expiration of its entries. The expiration interval can be fixed or relative.

To configure content group expiration by using the command line interface

At the command prompt, type:

```
set cache contentgroup \<name> (-relExpiry|-relExpiryMilliSec|-
absExpiry|-absExpiryGMT| -heurExpiryParam|-weakPosRelExpiry|-weakNegRelExpiry
| -expireAtLastBye)\<expirationValue>
```

To configure content group expiration by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, select the content group, and specify expiry method.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Expire individual responses

Expiring a response forces the Citrix ADC appliance to fetch a refreshed copy from the origin server. Responses that do not have validators, for example, ETag or Last-Modified headers, cannot be revalidated. As a result, flushing these responses has the same effect as expiring them.

To expire a cached response in a content group for static data, you can specify a URL that must match the stored URL. If the cached response is part of a parameterized content group, you must specify the group name and the exact URL stem. The host name and the port number must be the same as in the host HTTP request header of the cached response. If the port is not specified, port 80 is assumed.

To expire individual responses in a content group by using the command line interface

At the command prompt, type:

```
expire cache object -url <URL> -host <hostName> [-port <port>] [-
groupName<contentGroupName>] [-httpMethod GET|POST]
```

To expire individual responses in a content group by using the CLI

At the command prompt, type the following command:

```
expire cache object -locator <positiveInteger>
```

To expire a cached response by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cached Objects**, select the cached response, and expire.

To expire a response by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cached Objects**, click **Search** and, set the search criteria to find the required cached response and expire.

Flushing responses in a content group

You can remove, or flush, all responses in a content group, some responses in a group, or all responses in the cache. Flushing a cached response frees up memory for new cached responses.

> **Note:**
>
> To flush responses for more than one object at a time, use the configuration utility method. The command line interface does not offer this option.

To flush responses from a content group by using the command line interface

At the command prompt, type:

```
flush cache contentGroup <name> [-query <queryString> | [-selectorValue
 <selectorExpressionIDList> -host <hostName>]]
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To flush responses from a content group by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**.
2. In the details pane, flush the responses as follows:
   - To flush all responses in all content groups, click Invalidate All, and flush all the responses.
   - To flush responses in a particular content group, select the content group, click **Invalidate**, and flush all the responses.

> **Note**:
> If this content group uses a selector, you can selectively flush responses by entering a string in the Selector value text box, entering a host name in the Host text box. Then click **Flush and OK**. The Selector value can be a query string of up to 2319 characters that is used for parameterized invalidation.

If the content group uses an invalidation parameter, you can selectively flush responses by entering a string in the **Query** field.

If the content group uses an invalidation parameter and Invalidate objects belonging to the target host is configured, enter strings in the **Query and Host** fields.

To flush a cached response by using the command line interface

At the command prompt, type:

```
flush cache object -locator <positiveInteger> | -url <URL> -host <
hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod
 GET|POST]
```

To flush a cached response by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cached Objects**, select the cached object, and flush.

Deleting a content group

You can remove a content group if it is not used by any policy that stores responses in the cache. If the content group is bound to a policy, you must first remove the policy. Removing the content group removes all responses stored in that group.

You cannot remove the Default, BASEFILE, or Deltas group. The Default group stores cached responses that do not belong in any other content group.

To delete a content group by using the command line interface

At the command prompt, type:

```
rm cache contentgroup <name>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To delete a content group by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Content Groups,** select the content group, and delete.

Configure policies for caching and invalidation

September 14, 2021

Policies enable the integrated cache to determine whether to try to serve a response from the cache or the origin. The NetScaler appliance provides built-in policies for integrated caching, and you can configure more policies. When you configure a policy, you associate it with an action. An action either caches the objects to which the policy applies or invalidates (expires) the objects. Typically, you based caching policies on information in GET and POST requests. You typically base invalidation policies on the presence of the POST method in requests, along with other information. You can use any information in a GET or POST request in a caching or an invalidation policy.

You can view some of the built-in policies in the integrated cache's Policies node in the configuration utility. The built-in policy names begin with an underscore (_).

Actions determine what the NetScaler appliance does when traffic matches a policy. The following actions are available:

- **Caching actions**. Policies that you associate with the CACHE action store responses in the cache and serve them from the cache.
- **Invalidation actions**. Policies that you associate with the INVAL action immediately expire cached responses and refresh them from the origin server. For Web-based applications, invalidation policies often evaluate POST requests.
- **"Do not cache"actions**. Policies that you associate with a NOCACHE action never store objects in the cache.
- **Provisionally cache actions**. Policies that you associate with a MAYCACHE or MAYNOCACHE action depend on the outcome of more policy evaluations.

Although the integrated cache does not store objects specified by the LOCK method, you can invalidate cached objects upon receipt of a `LOCK` request. For invalidation policies only, you can specify `LOCK` as a method by using the expression `http.req.method.eq("lock")`. Unlike policies for `GET` and `POST` requests, you must enclose the LOCK method in quotes because the NetScaler appliance recognizes this method name as a string only.

After you create a policy, you bind it to a particular point in the overall processing of requests and responses. Although you create a policy before binding it, you must understand how the bind points affect the order of processing before you create your policies.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The policies bound to a particular bind point constitute a policy bank. You can use goto expressions to modify the order of execution in a policy bank. You can also invoke policies in other policy banks. In addition, you can create labels and bind policies to them. Such a label is not associated with a processing point, but the policies bound to it can be invoked from other policy banks.

Actions to associate with integrated caching policies

The following table describes actions for integrated caching policies.

Action	Specification
CACHE	Serves a response from the cache if the response has not expired. If the response must be fetched from the origin server, the NetScaler appliance caches the response before serving it. Even data that is updated and accessed frequently can be cached. For example, stock quotes are updated frequently, but they can be cached so that they can be served quickly to multiple users. If necessary, cached data can be refreshed immediately after it is downloaded. A CACHE action can be overridden by built-in policies.
NOCACHE	Always fetches the response from the origin server and marks the response as non-storable. You typically configure NOCACHE policies for data that is sensitive or personalized.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Action	Specification
MAY_CACHE	Used in a request-time policy, this setting provisionally enables a response to be stored in a content group, pending evaluation of response-time policies. The following are possible: 1. If a matching response-time policy has a CACHE action but does not specify a content group, the response is stored in the Default group unless built-in policies override this policy. 2. If a matching response-time policy has a CACHE action and specifies the same content group as the one in the request-time policy, the response is stored in the named content group unless built-in policies override this policy. 3. If a matching response-time policy has a CACHE action but specifies a different content group from the one in the request-time policy, a NOCACHE action is applied. 4. If a matching response-time policy has a NOCACHE action, perform a NOCACHE action. 5. If there is no matching response-time policy, a CACHE action is applied, unless a built-in policy overrides this policy.
MAY_NOCACHE	For a request-time policy, this setting provisionally prevents caching the response. At response time, one of the following actions is taken: - If no response-time policy matches the request, the final action is NOCACHE. - If a matching response-time policy contains a CACHE action, the final action is CACHE, unless built-in policies override this policy. - If a matching response-time policy contains a NOCACHE action, the final action is NOCACHE. -If a matching response-time policy has a CACHE action but does not specify a content group, the final action is to CACHE the response in the Default content group, unless built-in policies override this policy.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Action	Specification
INVAL	Expires cached responses. Depending on how the policy and the content group are configured, all responses in one or more content groups are expired, or selected objects in the content group are expired. Note: You can specify INVAL actions in request-time policies only.

Bind points for a policy

You can bind the policy to one of the following bind points:

- **A global policy bank**. These are the request-time default, request-time override, response-time default, and response-time override policy banks, as described in "Order of Policy Evaluation."
- **A virtual server**. Policies that you bind to a virtual server are processed after the global override policies and before the global default policies, as described in "Order of Policy Evaluation." When binding a policy to a virtual server, you bind it to either request-time or response-time processing.
- **An ad-hoc policy label**. A policy label is a name assigned to a policy bank. In addition to the global labels, the integrated cache has two built-in custom policy labels:
  - _reqBuiltinDefaults. This policy label, by default, is invoked from the request-time default policy bank.
  - _resBuiltinDefaults. This policy label, by default, is invoked from the response-time default policy bank.

You can also define new policy labels. Policies bound to a user-defined policy label must be invoked from within a policy bank for one of the built-in bind points.

> **Important:**
> You must bind a policy with an INVAL action to a request-time override or a response-time override bind point. To delete a policy, you must first unbind it.

Order of policy evaluation

For an advanced policy to take effect, you must ensure that the policy is invoked at some point during the NetScaler appliance's processing of traffic. To specify the invocation time, you associate the policy with a bind point. The following are the bind points, listed in order of evaluation:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Request-time override**. If a request matches a request-time override policy, by default the request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time load balancing virtual server**. If policy evaluation cannot be completed after all the request-time override policies are evaluated, the NetScaler appliance processes request-time policies that are bound to load balancing virtual servers. If the request matches one of these policies, evaluation ends and the NetScaler appliance store the action that is associated with the matching policy.
- **Request-time content switching virtual server**. Policies that are bound to this bind point are evaluated after the request-time policies that are bound to load balancing virtual servers.
- **Request-time default**. If policy evaluation cannot be completed after all the request-time, virtual server-specific policies are evaluated, the NetScaler appliance processes the request-time default policies. If the request matches a request-time default policy, by default the request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Response-time override**. Similar to request-time override policy evaluation.
- **Response-time load balancing virtual server**. Similar to request-time virtual server policy evaluation.
- **Response-time content switching virtual server**. Similar to request-time virtual server policy evaluation.
- **Response-time default**. Similar to request-time default policy evaluation.

You can associate multiple policies with each bind point. To control the order of evaluation of the policies associated with the bind point you configure a priority level. In the absence of any other flow control information, policies are evaluated according to priority level, starting with the lowest numeric priority value.

> **Note:**
> Request-time policies for POST data or cookie headers must be invoked during request-time override evaluation, because the built-in request-time policies in the integrated cache return a `NOCACHE` action for POST requests and a `MAY_NOCACHE` action for requests with cookies. You would associate `MAY_CACHE` or `MAY_NOCACHE` actions with a request-time policy that points to a parameterized content group. The response time policy determines whether the transaction is stored in the cache.

Configure a policy for integrated caching

You configure new policies to handle data that the built-in policies cannot process. You configure separate policies for caching, preventing caching from occurring, and for invalidating cached data. Following are the main components of a policy for integrated caching:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Rule: A logical expression that evaluates an HTTP request or response.
- Action: You associate a policy with an action to determine what to do with a request or response that matches the policy rule.

Content groups: You associate the policy with one or more content groups to identify where the action is to be performed.

To configure a policy for caching by using the command line interface

At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -actionCACHE|MAY_CACHE
|NOCACHE|MAY_NOCACHE [-storeInGroup <contentGroupName>] [-undefAction
 NOCACHE|RESET]
> add cache policy image_cache -rule "http.req.url.contains(\"jpg
\")|| http.req.url.contains(\"jpeg\")"-action CACHE -storeingroup
myImages_group -undefaction NOCACHE

> add cache policy bugReportPolicy -rule "http.req.url.query.contains
(\"IssuePage\")"-action CACHE -storeInGroup bugReportGroup

> add cache policy my_form_policy -rule "http.req.header(\"Host
\")contains(\"my.company.com\")&& http.req.method.eq(\"GET\")&&
http.req.url.query.contains(\"v=7\")"-action CACHE -storeInGroup
my_form_event

> add cache policy viewproducts_policy –rule "http.req.url.contains
(\"viewproducts.aspx\")"–action CACHE -storeInGroup Product_Details
```

To configure a policy for invalidation by using the command line interface

At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -action INVAL [-
    invalObjects "\<contentGroupName1>[,<selectorName1>"]. . .]] | [-
    invalGroup \<contentGroupName1>[, <contentGroupName2>. . .]] [-
    undefAction NOCACHE|RESET]
```

```
> add cache policy invalidation_events_policy -rule "http.req.header("
    Host")contains("my.company.com") && http.req.method.eq("GET") &&
    http.req.url.query.contains("v=8") -action INVAL -invalObjects
    my_form_event -undefaction NOCACHE
```

```
> add cache policy inval_all -rule "http.req.method.eq("POST") && http.
    req.url.contains("jpeg")" -action INVAL -invalGroups myImages_group
    myApps_group PDF_group
```

```
> add cache policy bugReportInvalidationPolicy -rule "http.req.url.
    query.contains(\"TransitionForm\")" -action INVAL -invalObjects
    bugReport`
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
`> add cache policy editproducts_policy  – rule "http.req.url.contains
   (\"editproducts.aspx\")"  – action INVAL -invalObjects "
   Product_Details,batchnum_sel" "Products_In_Depots,batchid_sel"
```

To configure a policy for caching or invalidation by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Policies**, and create the new policy.

Globally binding an integrated caching policy

When you globally bind a policy, it is available to all virtual servers on the NetScaler appliance.

To bind an integrated caching policy globally by using the command line interface:

At the command prompt, type:

```
bind cache global <policy> -priority <positiveInteger> [-
   typeREQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT] [-
   gotoPriorityExpression <expression>] [-invoke <labelType> <labelName
   >]
```

```
> bind cache global myCachePolicy -priority 100 -type req_default
```

> **Note:**
>
> The type argument is optional for globally bound policies, to maintain backward compatibility with policies that you defined using earlier versions of the NetScaler appliance. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression. If the rule contains both request time and response time parameters, it is bound to RES_DEFAULT. Following is an example of a binding that omits the type

Following is an example of a binding that omits the type.

```
> bind cache global myCache Policy 200
```

To bind an integrated caching policy globally by using the configuration utility

Navigate to **Optimization** > **Integrated Caching**, click **Cache Policy Manager** and bind policies by specifying the relevant bind point and connection type (Request/Response).

Bind an integrated caching policy to a virtual server

When you bind a policy to a virtual server, it is available only to requests and responses that match the policy and that flow through the relevant virtual server.

When using the GUI, you can bind the policy using the configuration dialog box for the virtual server. This enables you to view all of the policies from all Citrix ADC modules that are bound to this virtual

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

server. You can also use the **Policy Manager configuration** dialog for the integrated cache. This enables you to view only the integrated caching policies that are bound to the virtual server.

To bind an integrated caching policy to a virtual server by using the command line interface:

At the command prompt, type:

```
bind lb vserver <name>@ -policyName <policyName> -priority <
    positiveInteger> -type(REQUEST|RESPONSE)
```

```
bind cs vserver <name>@ -policyName <policyName> -priority <
    positiveInteger> -type(REQUEST|RESPONSE)
```

To bind an integrated caching policy to a virtual server by using the configuration utility (virtual server method)

- CS Virtual Server - Navigate toTraffic **Management > Content Switching > Virtual Servers**, select the virtual server, and bind relevant cache policies.
- LB Virtual Server - Navigate toTraffic **Management > Load Balancing > Virtual Servers**, select the virtual server, and bind relevant cache policies.

To bind an integrated caching policy to a virtual server by using the GUI (Policy Manager method).

Navigate to **Optimization** > **Integrated Caching**, click **Cache Policy Manager**, and bind cache policies by specifying the relevant bind point and connection type.

> **Note:**
> You can bind cache policies to both load balancing virtual server and content switching virtual server by selecting the appropriate bind point.

How to cache compressed and uncompressed versions of a file

By default, a client that can handle compression can be served uncompressed responses or compressed responses in gzip, deflate, compress, and pack200-gzip format. If the client handles compression, an `Accept-Encoding:compression` format header is sent in the request. The compression type accepted by the client must match the compression type of the cached object. For example, a `cached.gzip` file cannot be served in response to a request with an `Accept-Encoding:deflate` header.

A client that cannot handle compression is served a cache miss if the cached response is compressed.

For dynamic caching, you need to configure two content groups, one for compressed data and one for uncompressed versions of the same data. The following is an example of configuring the selectors, content groups, and policies for serving uncompressed files from the cache to clients that cannot

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

handle compression, and serving compressed versions of the same files to the client that can handle compression.

```
add cache selector uncompressed_response_selector http.req.url "http.
req.header(\"Host\")"

add cache contentGroup uncompressed_group -hitSelector uncompressed_responst_s
 -invalSelector uncomp_resp_sel

add cache policy cache_uncompressed -rule "HTTP.REQ.URL.CONTAINS(\"
xyz\")&& !HTTP.REQ.HEADER(\"Accept-Encoding\").EXISTS"-action CACHE -
storeInGroup uncompressed_group

bind cache global cache_uncompressed -priority 100 -gotoPriorityExpression
 END -type REQ_OVERRIDE

add cache selector compressed_response_selector HTTP.REQ.URL "HTTP.
REQ.HEADER(\"Host\")""HTTP.REQ.HEADER(\"Accept-Encoding\")"

add cache contentGroup compressed_group -hitSelector compressed_response_selec

add cache policy cache_compressed -rule "HTTP.REQ.URL.CONTAINS(\"
xyz\")&& HTTP.REQ.HEADER(\"Accept-Encoding\").EXISTS"-action CACHE -
storeInGroup compressed_group

bind cache global cache_compressed -priority 200 -gotoPriorityExpression
 END -type REQ_OVERRIDE
```

Configure a policy bank for caching

All of the policies that are associated with a particular bind point are collectively known as a policy bank. In addition to configuring priority levels for policies in a bank, you can modify the order of evaluation in a bank by configuring Goto expressions. You can further modify the evaluation order by invoking an external policy bank from within the current policy bank. You can also configure new policy banks, to which you assign your own labels. Because such policy banks are not bound to any point in the processing cycle, they can be invoked only from within other policy banks. For convenience, policy banks whose labels do not correspond to a built-in bind point are called policy labels.

In addition to controlling the order of policy evaluation by binding the policy and assigning a priority level, as described in "Binding Policies", you can establish the flow within a bank of policies by configuring a Goto expression. A Goto expression overrides the flow that is determined by the priority levels. You can also control the evaluation flow by invoking an external policy bank after evaluating an entry in the current bank. Evaluation always returns to the current bank after evaluation has completed.

The following table summarizes the entries to control evaluation in a policy bank.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Attribute	Specifies
Name	The name of a policy, or, to invoke another policy bank without evaluating the policy, the keyword NOPOLICY. You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.
Priority	An integer. The lower the integer, the higher the priority.
Goto Expression	Determines the next policy or policy bank to evaluate. You can provide one of the following values: 1. NEXT: Go to the policy with the next higher priority. 2. END: Stop evaluation. 3. USE_INVOCATION_RESULT: Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT. 4. Positive number: Priority number of the next policy to be evaluated. 5. Numeric expression: Expression that produces the priority number of the next policy to be evaluated. The Goto can only proceed forward in a policy bank. Omitting the Goto expression is the same as specifying END.
Invocation Type	Designates a policy bank type. The value can be one of the following - 1. Request virtual server: Invokes request-time policies that are associated with a virtual server. 2. Response virtual server: Invokes response-time policies that are associated with a virtual server. 3. Policy label: Invokes another policy bank, as identified by the policy label for the bank.
Invocation Name	Name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

The integrated cache has two built-in policy labels, and you can configure more policy labels:

`_reqBuiltInDefaults`: This policy label is invoked from the request-time default bind point.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

`_resBuiltInDefaults`: This policy label is invoked from the response-time default bind point.

To invoke a policy label in a caching policy bank by using the command line interface

At the command prompt, type:

```
bind cache policylabel <labelName> -policname<policyName> -priority<
    priority> [-gotoPriorityExpression <gotoprioritыExpression>] [-
    invoke <labelType> <labelName>]
```

To invoke a policy label in a caching policy bank by using the GUI:

1. Navigate to **Optimization** > **Integrated Caching**, click **Cache policy manager**, and specify the relevant bind point (Override Global or Default Global) and connection type to view the list of policies bound to this bind point.
2. If you want to invoke a policy label without evaluating a policy, click **NOPOLICY**.

> **Note:**
>
> To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name.

To invoke a caching policy label in a virtual server policy bank by using the command line interface

At the command prompt, type:

```
bind lb vserver <name>@ -policyName <policyName>|<NOPOLICY-CACHE> -
    priority<positiveInteger> -gotoPriorityExpression <expression> -type
     REQUEST|RESPONSE -invoke<labelType> <labelName>
```

```
bind cs vserver <name> -policyName <policyName>|<NOPOLICY-CACHE> -
    priority<positiveInteger> -gotoPriorityExpression <expression> -type
     REQUEST|RESPONSE -invoke<labelType> <labelName>
```

To invoke a caching policy label in a virtual server policy bank by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing/Content Switching** > **Virtual Servers**, select the virtual server, and click **Policies**.
2. If you are configuring an existing entry in this bank, skip this step. If you are adding a new policy to this policy bank, or you want to use the “dummy”NOPOLICY entry, click **Add** and do one of the following:
    - To configure a new policy, click Cache and configure the new policy as described in Configuring a Policy in the Integrated Cache.
    - To invoke a policy bank without processing a policy a rule, select the `NOPOLICY-CACHE` option.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:**
>
> To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name.

Configure a policy label in an integrated cache

In addition to configuring policies in a policy bank for one of the built-in bind points or a virtual server, you can create caching policy labels and configure banks of policies for these new labels.

A policy label for the integrated cache can be invoked only from one of the bind points that you can view in the Policy Manager in the **Integrated Caching** details pane (request override, request default, response override, or response default) or the built-in policy labels `\\_reqBuiltinDefaults` and `\\_resBuiltinDefaults`. You can invoke a policy label any number of times unlike a policy, which can only be invoked once.

The Citrix ADC GUI provides an option to rename a policy label. Renaming a policy label does not affect the process of evaluation of the policies bound to the label.

> **Note**:
>
> You can use the `NOPOLICY` "dummy"policy to invoke any policy label from another policy bank. The `NOPOLICY` entry is a placeholder that does not process a rule.

To configure a policy label for caching by using the command line interface

At the command prompt, type the following command to create a policy label and verify the configuration:

- `add cache policylabel <labelName> -evaluates (REQ|RES)`
- `show cache policylabel <labelName>`

Invoke this policy label from a policy bank.

To configure a policy label for caching by using the GUI:

Navigate to **Optimization** > **Integrated Caching** > **Policy Labels**, add a policy label, and bind the cached policies.

> **Note:**
>
> To ensure that the Citrix ADC processes the policy label at the right time, configure an invocation of this label in one of the policy banks that are associated with the built-in bind points.

To rename a policy label by using the GUI:

Navigate to **Optimization** > **Integrated Caching** > **Policy Labels** select the policy label, and rename.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Unbind and delete an integrated caching policy and policy label

You can unbind a policy from a policy bank, and you can delete it. To delete the policy, you must first unbind it. You can also remove a policy label invocation and delete a policy label. To delete the policy label, you must first remove any invocations that you have configured for the label.

You cannot unbind or delete the labels for the built-in bind points (request default, request override, response default, and response override).

To unbind a global caching policy by using the command line interface

At the command prompt, type:

```
unbind cache global <policy>
```

To unbind a virtual server-specific caching policy by using the command line interface

At the command prompt, type:

```
(unbind lb vserver|unbind cs vserver)<vserverName> -policyName <
policyName> -type(REQUEST|RESPONSE)
```

To delete a caching policy by using the command line interface

At the command prompt, type:

```
rm cache policy <policyName>
```

To unbind a caching policy by using the GUI:

Navigate to **Optimization** > **Integrated Caching**, click **Cache Policy Manager**, and unbind policies by specifying the relevant bind point and connection type (Request/Response).

To delete a policy label invocation by using the GUI:

1. Navigate to **Optimization** > **Integrated Caching**, click **Cache policy manager**, and specify the relevant binding point (load balancing virtual server or content switching virtual server) and connection type to view the list of cache policies bound to this virtual server.
2. In the policy Invoke column, clear the entry.

Cache support for database protocols

September 14, 2021

The integrated cache feature monitors and caches database request as determined by the cache policies. Users must configure the cache policies for MYSQL and MSSQL protocols as the Citrix ADC appliance does not provide any default policies. When configuring the default protocols, remember the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

request-based policies support only CACHE and INVAL actions, while the response-based policies support only "NOCACHE"action. After configuring the policies, you must bind them to virtual servers. MYSQL and MSSQL policies, both request and response, are bound only to virtual servers.

Before creating a cache policy, you must create a cache content group of type MYSQL or MSSQL. When you create a cache content group, associate at least one select selector with it. See Setting Up a Basic Content Group for setting up a cache content group.

The following example explains how to configure and verify cache support for SQL protocols.

```
> enable feature IC
> set cache parameter -memlimit 100
> add cache selector sel1 mssql.req.query.text

> add cache contentgroup cg1  -type "MSSQL" -hitselector "sel1" -
   invalselector "inval_sel" -relExpiry "500" -maxResSize
 "100"
> add cache policy cp1  -rule "mssql.req.query.command.contains(\"
   select\")" -action "CACHE" -storeInGroup "cg1"
> add cache policy cp2  -invalObjects "cg1" -rule "mssql.req.query.text
   .contains(\"insert\")" -action "INVAL"
> add db user user1  -password "Pass1"
> add service svc_sql_1 10.102.147.70 mssql 64834 -healthMonitor "NO" -
   downstateflush "ENABLED"
> add lb vserver lb_mssql1 mssql 10.102.147.77 1433  -lbmethod "
   roundrobin"
> bind lb vserver lb_mssql1 svc_sql_1
> bind lb vserver lb_mssql1 -policyName cp1  -type "REQUEST" -priority
   "2"
> bind lb vserver lb_mssql1 -policyName cp2  -type "REQUEST" -priority
   "1"

> show cache selector sel1
     Name:sel1
                    Expressions:
                    1)mssql.req.query.text
> show cache policy cp1
                    Name:cp1
     Rule:mssql.req.query.command.contains("select")
                    CacheAction:CACHE
                    Stored in group: cg1
                    UndefAction:Use Global
                Hits:2
                    Undef Hits:0
                    Policy is bound to following entities
                    1) Bound to:
                                REQ VSERVER lb_mssql1
                                Priority:2
                                GotoPriorityExpression: END
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:**
>
> The methods for reducing flash crowds, as explained in Reducing Flash Crowds, are not supported for MYSQL and MSSQL protocols.

Configure expressions for caching policies and selectors

November 2, 2023

A request-time expression examines data in the request-time transaction, and a response-time expression examines data in a response-time transaction. In a policy for caching, if an expression matches data in a request or response, the Citrix ADC appliance takes the action associated with the policy. In a selector, request-time expressions are used to find matching responses that are stored in a content group.

Before configuring policies and selectors for the integrated cache, you need to know, at minimum, the host names, paths, and IP addresses that appear in HTTP request and response URLs. And you probably need to know the format of entire HTTP requests and responses. Programs such as Live HTTP Headers `http://livehttpheaders.mozdev.org/)or HTTPFox https://addons.mozilla.org/en-US/firefox/addon/6647` can help you investigate the structure of the HTTP data that your organization works with.

Following is an example of an HTTP GET request for a stock quote program:

```
GET /quote.dll?page=dynamic&mode=data&mode=stock&symbol=CTXS&page=multi
    &selected=CTXS&random=0.00792039478975548 HTTP/1.1

Host: quotes.mystockquotes.com

User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9)
    Gecko/2008052906 Firefox/3.0

Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8

Accept-Language: en-us,en;q=0.5

Accept-Encoding: gzip,deflate,compress,pack200-gzip

Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7

Keep-Alive: 300

Connection: keep-alive

Referer: http://quotes.mystockquotes.com/quote.dll?mode=stock&symbol=
    CTXS&page=multi&selected=CTXS
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
20
21 Cookie: __qca=1210021679-72161677-10297606
```

When configuring an expression, note the following limitations:

Expression Type	Restrictions
Request	Do not configure request-time expressions in a policy with a CACHE or NOCACHE action. Use MAY_CACHE or MAY_NOCACHE instead.
Response	Configure response-time expressions in caching policies only. Selectors can use only request-time expressions, Do not configure response-time expressions in a policy with an INVAL action. Note: Do not configure response-time expressions in a policy with a CACHE action and a parameterized content group. Use the MAY_CACHE action.

> **Note:**
> For a comprehensive discussion of advanced expressions, see Policies and Expression.

Expression syntax

Following are the basic components of the syntax:

- Separate keywords with periods (.), as follows:

```
http.req.url
```

- Enclose string values in parentheses and quotes, as follows:

```
http.req.url.query.contains("this")
```

- When configuring an expression from the command line, you must escape internal quote marks (the quotes that delimit the values in the expression, as opposed to the quotes that delimit the expression). One method is to use a slash, as followings:

```
\"abc\"
```

Selector expressions are evaluated in order of appearance, and multiple expressions in a selector definition are joined by a logical AND. Unlike selector expressions, you can specify Boolean operators and modify the precedence in an advanced expression for a policy rule.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure an expression in a caching policy or a selector

> **Note:**
> The syntax for a policy expression is different from a selector expression. For a comprehensive discussion of advanced expressions, see "Policies and Expressions."

To configure a policy expression by using the command line interface

1. Start the policy definition as described in "Globally Binding an Integrated Caching Policy."
2. To configure the policy rule, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

"http.req.url.contains("jpg")"

To add Boolean values, insert &&,

1.

The following are examples:

```
"http.req.url.contains(\"jpg\")|| http.req.url.contains(\"jpeg\")"
```

```
"http.req.url.query.contains(\"IssuePage\")"
```

```
"http.req.header(\"Host\")contains(\"my.company.com\")&& http.req.
method.eq(\"GET\")&& http.req.url.query.contains(\"v=7\")"
```

1. To configure an order of evaluation for the constituent parts of a compound

```
"http.req.url.contains(\"jpg\")|| (http.req.url.contains(\"jpeg\")&&
http.req.method.eq(\"GET\"))"
```

To configure a selector expression by using the command line interface:

1. Start the selector definition as described in "About Content Groups."
2. To configure the selector expression, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

```
"http.req.url.contains(\"jpg\")"
```

You cannot add Boolean values, insert &&,

1.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following are examples:

```
"http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"
   BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
```

To configure a policy or selector expression by using the GUI

1. Start the policy or selector definition as described in "To configure a policy for caching or invalidation by using the configuration utility"or "To configure a selector by using the configuration utility."
2. In the **Expression** field, you can either manually type the default syntax by clicking Switch to Classic Syntax or create new expression using **Expression Editor**.

To insert an operator between two parts of a compound expression, click the Operators button and select the operator type. The following is an example of a configured expression with a Boolean OR (signaled by double vertical bars,

---

3.
4. Click **Frequently Used Expressions** drop-down list to insert the commonly used expressions.
5. To test the expression, click the **Evaluate**. In the **Expression Evaluator** dialog box, select the Flow Type that matches the expression. In the data field, paste the HTTP request or response that you hope to parse using the expression, and click **Evaluate**.

Display cached objects and cache statistics

You can view particular cached objects, and you can view summary statistics on cache requests, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics

View cached objects

After enabling caching, you can view details for cached objects. For example, you can view the following items:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

Properties	Description
Response size (bytes)	The size of the response header and body.
Response header size (bytes)	The size of the header portion of the response.
Response status code	The status code sent with the response.
ETag	The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.
Last-Modified	The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.
Cache-Control	The Cache-Control header inserted in the response.
Date	The Date header that indicates when the response was sent.
Contentgroup	The content group where the response is stored.
Complex match	If this object was cached based on parameterized values, this field value is YES.
Host	The host specified in the URL that requested this response.
Host port	The listen port for the host specified in the URL that requested this response
URL	The URL issued for the stored response.
Destination IP	The IP address of the server from which this response was fetched.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Properties	Description
Destination port	The listen port for the destination server.
Hit parameters	If the content group that stores the response uses hit parameters, they are listed in this field.
Hit selector	If this content group uses a hit selector, it is listed in this field.
Inval selector	If this content group uses an invalidation selector, it is listed in this field.
Selector Expressions	If this content group uses a selector, this field displays the expression that defines the selection rule.
Request time	The time in milliseconds since the request was issued.
Response time	The time in milliseconds since the cache started to receive the response.
Age	Amount of time the object has been in the cache.
Expiry	Amount of time after which the object is marked as expired.
Flushed	Whether the response has been flushed after expiry.
Prefetch	If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 “object not found”responses).
Current readers	Approximately the current number of requests being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Properties	Description
Current misses	The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.
Hits	The number of cache hits for this object.
Misses	The number of cache misses for this object
Compression format	The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.
HTTP version in response	The version of HTTP that was used to send the response.
Weak etag present in response	Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a "W."
Negative marker cell	A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.
Reason marker created	The reason a marker cell was created (for example, "Waiting for minhit,"*"Content-length response data is not in group size limit").
Auto poll every time	If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).
Citrix ADC Etag inserted in response	A variation of the ETag header generated by the Citrix ADC appliance. A value of YES appears if the Citrix ADC inserts an Etag in the response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Properties	Description
Full response present in cache	Indicates whether this is a complete response.
Destination IP verified by DNS	Indicates whether DNS resolution was performed when storing the object.
Object stored through a cache forward proxy	Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.
Object is a Delta basefile	A response that is delta-compressed.
Waiting for minhits	Indicates whether this content group requires a minimum number of origin servers hit before caching a response.
Minhit count	If this content group requires a minimum number of origin server requests before caching an object, this field displays a count of the number of requests received so far.
HTTP Request Method	The method, GET or POST, used in the request that obtained this object.
Stored by policy	The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.
Application firewall metadata exists	This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Properties	Description
HTTP callout object, name, type, response	These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see "HTTP Callouts".

To view cached objects by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cache Objects**. You can view all the cached objects and sort them accordingly as per your requirement.

Find particular cached responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

- If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.
- If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select **Copy**. For more information about selectors, see "Configuring Selectors and Basic Content Groups."

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

```
show cache object [-locator <positiveInteger>] | [(-url <URL> (-
host <hostName> [-port <port>] [-groupName <contentGroupName>]
[-httpMethod GET | POST ]))| [-httpStatus <positive integer>] |
 -group <contentGroupName> | -ignoreMarkerObjects (ON | OFF)| -
includeNotReadyObjects (ON | OFF)]
```

To display cached responses in content groups that have a selector by using the command line interface

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

At the command prompt, type:

```
show cache object -locator <locatorString> MarkerObjects ( ON | OFF )
| -includeNotReadyObjects ( ON | OFF )| [-httpStatus<positive integer
>]
```

To display cached responses in content groups that do not have a selector by using the configuration utility

Navigate to **Optimization > Integrated Caching > Cache Objects**, click Search, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

View cache statistics

The following table summarizes the detailed cache statistics that you can view.

Counter	Description
Hits	Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action.
Misses	Intercepted HTTP requests where the response was ultimately fetched from origin server.
Requests	Total cache requests plus total cache misses.
Non-304 hits This statistic indicates how many items the Citrix ADC appliance served from the cache, excluding 304 responses.	If the user requests an item more than once, and the item in the cache is unchanged since the last time the Citrix ADC appliance served it, the Citrix ADC appliance serves a 304 response instead of the cached object.
304 hits	Number of 304 (object not modified) responses the Citrix ADC appliance served from the cache.
304 hit ratio (%)	Percentage of 304 responses that the Citrix ADC appliance served, relative to other responses.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Counter	Description
Hit ratio (%)	Percentage of responses that the Citrix ADC appliance served from the cache (cache requests) relative to responses that could not be served from the cache.
Origin bandwidth saved (%)	An estimate of the processing capacity that the Citrix ADC appliance saved on the origin server due to serving responses from the cache.
Bytes served by the Citrix ADC	Total number of bytes that the Citrix ADC appliance served from the origin server and the cache.
Bytes served by cache	Total number of bytes that the Citrix ADC appliance served from the cache.
Byte hit ratio(%)	Percentage of data that the Citrix ADC appliance served from the cache, relative to all of the data in all served responses.
Compressed bytes from cache	Amount of data, in bytes, that the Citrix ADC appliance served in compressed form.
Storable misses	If the Citrix ADC appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.
Non-storable misses	A non-storable cache miss cannot be stored in the cache.
Misses	All cache misses.
Revalidations For more information, see ‘‘Inserting a Cache-Control Header.’’	Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user.
Successful revalidations For more information, see ‘‘Inserting a Cache-Control Header.’’	Number of revalidations that have been performed.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Counter	Description
Conversions to conditional req For more information, see "Polling the Origin Server Every Time a Request Is Received."	A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server.
Storable miss ratio (%)	Storable cache misses as a percentage of non-storable cache misses.
Successful reval ratio (%) For more information, see "Inserting a Cache-Control Header."	Successful revalidations as a percentage of all revalidation attempts.
Expire at last byte For more information, see "Example of Performance Optimization."	Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table "Cache Hits and Misses."
`Flashcache` misses For more information, "Queuing Requests to the Cache."	If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses.
Flashcache hits For more information, see "Queuing Requests to the Cache."	Number of Flash Cache requests that were cache hits.
Parameterized inval requests	Requests that match a policy with an invalidation (INVAL) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.
Full inval requests	Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.
Inval requests	Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Counter	Description
Parameterized requests	Number of cache requests that were processed using a policy with a parameterized content group.
Parameterized non-304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.
Parameterized 304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.
Total parameterized hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.
Parameterized 304 hit ratio (%)	Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.
Poll every time requests For more information, see "Polling the Origin Server Every Time a Request Is Received."	If Poll Every Time is enabled, the Citrix ADC appliance always consults the origin server before serving a stored object.
Poll every time hits For more information, see "Polling the Origin Server Every Time a Request Is Received."	Number of times a cache hit was found using the Poll Every Time method.
Poll every time hit ratio (%)	Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Maximum memory (KB)	Maximum amount of memory in the Citrix ADC appliance that is allocated to the cache. For more information, see "Configuring Global Attributes for Caching."

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Counter	Description
Maximum memory active value (KB)	Maximum amount of memory (active value) that will be set after the memory is allocated to the cache. For more information, see "How to Configure the Integrated Caching Feature of a Citrix ADC Appliance for various Scenarios."
Utilized memory (KB)	Amount of memory that is actually being used.
Memory allocation failures	Number of failed attempts to utilize memory for the purpose of storing a response in the cache.
Largest response so far	Largest response in bytes found in either the cache or the origin server and sent to the client.
Cached objects	Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.
Marker objects	Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
Hits being served	Number of hits that have been served from the cache.
Misses being handled	Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

To view summary cache statistics by using the command line interface:

At the command prompt, type:

```
stat cache
```

To view specific cache statistics by using the command line interface:

At the command prompt, type:

```
stat cache -detail
```

```
1 > stat cache -detail
2
3 Integrated Cache Statistics - Detail

To view summary cache statistics by using the GUI

1. Click the **Dashboard** tab at the top of the page.
2. Scroll down to the **Integrated Caching** section of the window.
3. To see detailed statistics, click the More…link at the bottom of the table.

To view specific cache statistics by using the GUI

1. Click the **Reporting** tab at the top of the page.
2. Under Built-In Reports, expand **Integrated Cache**, and then click the report with the statistics you want to view.
3. To save the report as a template, click **Save As** and name the report. The saved report appears under **Custom** Reports.

Display cached objects and cache statistics

September 14, 2021

You can view particular cached objects, and you can view summary statistics on cache hits, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics

View cached objects

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

Properties	Specification
Response size (bytes)	The size of the response header and body.
Response header size (bytes)	The size of the header portion of the response.
Response status code	The status code sent with the response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Properties	Specification
ETag	The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.
Last-Modified	The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.
Cache-Control	The Cache-Control header inserted in the response.
Date	The Date header that indicates when the response was sent.
Contentgroup	The content group where the response is stored.
Complex match	If this object was cached based on parameterized values, this field value is YES.
Host	The host specified in the URL that requested this response.
Host port	The listen port for the host specified in the URL that requested this response
URL	The URL issued for the stored response.
Destination IP	The IP address of the server from which this response was fetched.
Destination port	The listen port for the destination server.
Hit parameters	If the content group that stores the response uses hit parameters, they are listed in this field.
Hit selector	If this content group uses a hit selector, it is listed in this field.
Inval selector	If this content group uses an invalidation selector, it is listed in this field.
Selector Expressions	If this content group uses a selector, this field displays the expression that defines the selection rule.
Request time	The time in milliseconds since the request was issued.
Response time	The time in milliseconds since the cache started to receive the response.
Age	Amount of time the object has been in the cache.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Properties	Specification
Expiry	Amount of time after which the object is marked as expired.
Flushed	Whether the response has been flushed after expiry.
Prefetch	If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 "object not found"responses).
Current readers	Approximately the current number of hits being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.
Current misses	The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.
Hits	The number of cache hits for this object.
Misses	The number of cache misses for this object.
Compression format	The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.
HTTP version in response	The version of HTTP that was used to send the response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Properties	Specification
Weak etag present in response	Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a "W."
Negative marker cell	A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.
Reason marker created	The reason a marker cell was created (for example, "Waiting for minhit,"*"Content-length response data is not in group size limit").
Auto poll every time	If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).
Citrix ADC Etag inserted in response	A variation of the ETag header generated by the Citrix ADC appliance. A value of YES appears if the Citrix ADC inserts an Etag in the response.
Full response present in cache	Indicates whether this is a complete response.
Destination IP verified by DNS	Indicates whether DNS resolution was performed when storing the object.
Object stored through a cache forward proxy	Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.
Object is a Delta basefile	A response that is delta-compressed.
Waiting for minhits	Indicates whether this content group requires a minimum number of origin servers hit before caching a response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Properties	Specification
Minhit count	If this content group requires a minimum number of origin servers hit before caching an object, this field displays a count of the number of hits received so far.
HTTP Request Method	The method, GET or POST, used in the request that obtained this object.
Stored by policy	The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.
Application firewall metadata exists	This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session.
HTTP callout object, name, type, response	These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see "HTTP Callouts".

Find particular cached responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select Copy. For more information about selectors, see "Configuring Selectors and Basic Content Groups."

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

```
show cache object [-locator <positiveInteger>] | [(-url <URL> (-
host <hostName> [-port <port>] [-groupName <contentGroupName>] [-
httpMethod GET | POST ]))| [-httpStatus<positive integer>] | -group <
contentGroupName> | -ignoreMarkerObjects (ON | OFF)| -includeNotReadyObjects
 (ON | OFF)]
```

To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

```
show cache object -locator <locatorString> MarkerObjects ( ON | OFF )
| -includeNotReadyObjects ( ON | OFF )| [-httpStatus<positive integer
>]
```

To display cached responses in content groups that do not have a selector by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cache Objects**, click **Search**, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

To display cached responses in content groups that have a selector by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Cache Objects**, click **Search**, and set the selector search criteria to view the required cached response.

Viewing cache statistics

Updated: 2013-10-28

The following table summarizes the detailed cache statistics that you can view.

Counter	Specifies
Hits	Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action..
Misses	Intercepted HTTP requests where the response was ultimately fetched from origin server.
Requests	Total cache hits plus total cache misses.
Non-304 hits	If the user requests an item more than once, and the item in the cache is unchanged since the last time the Citrix ADC appliance served it, the Citrix ADC appliance serves a 304 response instead of the cached object. This statistic indicates how many items the Citrix ADC appliance served from the cache, excluding 304 responses.
304 hits	Number of 304 (object not modified) responses the Citrix ADC appliance served from the cache.
304 hit ratio (%)	Percentage of 304 responses that the Citrix ADC appliance served, relative to other responses.
Hit ratio (%)	Percentage of responses that the Citrix ADC appliance served from the cache (cache hits) relative to responses that could not be served from the cache.
Origin bandwidth saved (%)	An estimate of the processing capacity that the Citrix ADC appliance saved on the origin server due to serving responses from the cache.
Bytes served by the Citrix ADC	Total number of bytes that the Citrix ADC appliance served from the origin server and the cache.
Bytes served by cache	Total number of bytes that the Citrix ADC appliance served from the cache.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Counter	Specifies
Byte hit ratio(%)	Percentage of data that the Citrix ADC appliance served from the cache, relative to all of the data in all served responses.
Compressed bytes from cache	Amount of data, in bytes, that the Citrix ADC appliance served in compressed form.
Storable misses	If the Citrix ADC appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.
Non-storable misses	A non-storable cache miss cannot be stored in the cache.
Misses	All cache misses.
Revalidations	Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user. For more information, see "Inserting a Cache-Control Header."
Successful revalidations	Number of revalidations that have been performed. For more information, see "Inserting a Cache-Control Header."
Conversions to conditional req	A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Storable miss ratio (%)	Storable cache misses as a percentage of non-storable cache misses.
Successful reval ratio (%)	Successful revalidations as a percentage of all revalidation attempts. For more information, see "Inserting a Cache-Control Header."

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Counter	Specifies
Expire at last byte	Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table "Cache Hits and Misses." For more information, see "Example of Performance Optimization."
Flash cache misses	If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses. For more information, "Queuing Requests to the Cache."
Flashcache hits	Number of Flash Cache requests that were cache hits. For more information, see "Queuing Requests to the Cache."
Parameterized inval requests	Requests that match a policy with an invalidation (INVAL) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.
Full inval requests	Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.
Inval requests	Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.
Parameterized requests	Number of cache requests that were processed using a policy with a parameterized content group.
Parameterized non-304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Counter	Specifies
Parameterized 304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.
Total parameterized hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.
Parameterized 304 hit ratio (%)	Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.
Poll every time requests	If Poll Every Time is enabled, the Citrix ADC appliance always consults the origin server before serving a stored object. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Poll every time hits	Number of times a cache hit was found using the Poll Every Time method. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Poll every time hit ratio (%)	Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Maximum memory (KB)	Maximum amount of memory in the Citrix ADC appliance that is allocated to the cache. For more information, see "Configuring Global Attributes for Caching."
Maximum memory active value (KB)	Maximum amount of memory (active value) that will be set after the memory is actually allocated to the cache. For more information, see "How to Configure the Integrated Caching Feature of a Citrix ADC Appliance for various Scenarios."
Utilized memory (KB)	Amount of memory that is actually being used.
Memory allocation failures	Number of failed attempts to utilize memory for the purpose of storing a response in the cache.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Counter	Specifies
Largest response so far	Largest response in bytes found in either the cache or the origin server and sent to the client.
Cached objects	Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.
Marker objects	Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
Hits being served	Number of hits that have been served from the cache.
Misses being handled	Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

To view summary cache statistics by using the command line interface

At the command prompt, type:

```
stat cache
```

To view specific cache statistics by using the command line interface

At the command prompt, type:

```
1  stat cache -detail
2
3      > stat cache -detail
4      Integrated Cache Statistics - Detail
5      Integrated Cache Statistics - Summary
6                                                  Rate (/s)
                                                      Total

72      Memory allocation failures                         0
73      Largest response so far(B)                         0
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
74      Cached objects                                  0
75      Marker objects                                  0
76      Hits being served                               0
77      Misses being handled                            0
78       Done
```

To view summary cache statistics by using the GUI

1. Click the **Dashboard** tab at the top of the page.
2. Scroll down to the Integrated Caching section of the window.
3. To see detailed statistics, click the More…link at the bottom of the table.

To view specific cache statistics by using the GUI

1. Click the Reporting tab at the top of the page.
2. Under Built-In Reports, expand Integrated Cache, and then click the report with the statistics you want to view.
3. To save the report as a template, click Save As and name the report. The saved report appears under Custom Reports.

Improve cache performance

September 14, 2021

You can improve the performance of the integrated cache, including handling simultaneous requests for the same cached data, avoiding delays that are associated with refreshing cached responses from the origin server, and ensuring that a response is requested often enough to be worth caching.

Reduce flash crowds

Flash crowds occur when many users simultaneously request the same data. The requests in a flash crowd can become cache misses if you configured the cache to serve hits only after the entire object is downloaded.

The following techniques can reduce or eliminate flash crowds:

- **PREFETCH**: Refreshes a positive response before it expires to ensure that it never becomes stale or inactive. For more information, see "Refreshing a Response Prior to Expiration"section.
- **Cache buffering**: Starts serving a response to multiple clients when it receives the response header from the origin server, rather than waiting for the entire response to be downloaded. The only limit on the number of clients that can download a response simultaneously is the available system resources. The Citrix ADC appliance downloads and serves responses even if

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

the client that initiated the download halts before the download is complete. If the response exceeds the cache size or if the response is chunked, the cache stops storing the response, but service to the clients is not disrupted.

- **Flash Cache:** Flash Cache queues requests to the cache, and allows only one request to reach the server at a time.

For more information, see ‘‘Queuing Requests to the Cache’’section.

Refresh a response before expiration

To ensure that a cached response is fresh whenever it is needed, the PREFETCH option refreshes a response before its calculated expiration time. The prefetch interval is calculated after receiving the first client request. From that point onward, the Citrix ADC appliance refreshes the cached response at a time interval that you configure in the PREFETCH parameter.

This setting is useful for data that is updated frequently between requests. It does not apply to negative responses (for example, 404 messages).

To configure prefetch for a content group by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -prefetch YES [-prefetchPeriod <seconds
> | -prefetchPeriodMilliSec <milliseconds>] [-prefetchMaxPending <
positiveInteger>]
```

*To configure prefetch for a content group by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the **content group**.

On **Others** tab, in the Flash Crowd and Prefetch group, select **Prefetch** option, and specify the values in the Interval and Maximum number of pending prefetches text boxes.

Queue requests to the cache

The Flash Cache option queues requests that arrive simultaneously (a flash crowd), retrieves the response, and distributes it to all the clients whose requests are in the queue. If, during this process, the response becomes non-cacheable, the Citrix ADC appliance stops serving the response from the cache and instead serves the origin server’s response to the queued clients. If the response is not available, the clients receive an error message.

Flash Cache is disabled by default. You cannot enable Poll Every Time (PET) and Flash Cache on the same content group.

One disadvantage of Flash Cache is if the server replies with an error (for example, a 404 that is quickly remedied), the error is fanned out to the waiting clients.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note**:
> If Flash Cache is enabled, in some situations the Citrix ADC appliance is unable to correctly match the Accept-Encoding header in the client request with the Content-Encoding header in the response. The Citrix ADC appliance can assume that these headers match and mistakenly serve a hit. As a work-around, you can configure Integrated Caching policies to disallow serving hits to clients that do not have an appropriate Accept-Encoding header.

To enable Flash Cache by using the command line interface

At the command prompt, type:

```
set cache contentgroup <contentGroupName> -flashcache yes
```

To enable Flash Cache by using the GUI

Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.

On **Others** tab, in the Flash Crowd and Prefetch group, select **Prefetch** option.

Cache a response after a client halts a download

You can set the Quick Abort parameter to continue caching a response, even if the client halts a request before the response is in the cache.

If the downloaded response size is less than or equal to the Quick Abort size, the Citrix ADC appliance stops downloading the response. If you set the Quick Abort parameter to 0, all downloads are halted.

To configure quick abort size by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -quickAbortSize <integerInKBytes>
```

To configure quick abort size by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On **Memory** tab, set the relevant value in Quick Abort: Continue caching if more than text box.

Requiring a minimum number of server hits before caching

You can configure the minimum number of times that a response must be found on the origin server before it can be cached. You must consider increasing the minimum hits if the cache memory fills up quickly and has a lower-than-expected hit ratio.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The default value for the minimum number of hits is 0. This value caches the response after the first request.

To configure the minimum number of hits that are required before caching by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -minhits <positiveInteger>
```

To configure the minimum number of hits that are required before caching by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On **Memory** tab, set the relevant value in Do not cache, if hits are less than the text box.

Example for performance optimization

In this example, a client accesses a stock quote. Stock quotes are highly dynamic. You configure the integrated cache to serve the same stock quote to concurrent clients without sending multiple requests to the origin server. The stock quote expires after it is downloaded to the clients, and the next request is fetched from the origin server. This ensures that the quote is always up to date.

The following task overview describes the steps to configure the cache for the stock quote application.

Configure caching for a stock quote application

Create a content group for stock quotes

For more information, see "About Content Groups."

Configure the following for this content group:

1. On the **Expiry Method** tab, select the Expire after complete response received check box.
2. On the **Others** tab, select the **Flash Cache** check box, and click **Create**.
3. Add a cache policy to cache the stock quotes.

For more information, see "Configuring a Policy in the Integrated Cache."

Configure the following for the policy

1. In the **Action and Store in Group lists**, select **CACHE** and select the group that you defined in the previous step.
2. Click **Add**, and in the **Add Expression** dialog box configure an expression that identifies stock quote requests, for example: http.req.url.contains("cgi-bin/stock-quote.pl")
3. Activate the policy.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For more information, see "Globally Binding an Integrated Caching Policy."In this example, you bind this policy to request-time override processing and set the priority to a low value.

Configure cookies, headers, and polling

November 2, 2023

This topic explains how to configure cache manages cookies, HTTP headers, and origin server polling. This includes modifying the default behavior that causes the cache to diverge from documented standards, overriding HTTP headers that might cause cacheable content to not be stored in the cache, and configuring the cache to always poll the origin for updated content.

Divergence of cache behavior from the standards

By default, the integrated cache adheres to the following RFC standards:

- RFC 2616, "HTTP HTTP/1.1"
- The caching behaviors described in RFC 2617, "HTTP Authentication: Basic and Digest Access Authentication"
- The caching behavior described in RFC 2965, "HTTP State Management Mechanism"

The built-in policies and the Default content group attributes ensure conformance with most of these standards.

The default integrated cache behavior diverges from the specification as follows:

- There is a limited support for the Vary header. By default, any response containing a Vary header is considered to be non-cacheable unless it is compressed. A compressed response contains content-encoding: gzip, content-encoding: deflate, or content-encoding: pack200-gzip and is cacheable even if it contains the Vary: Accept-encoding header.
- The integrated cache ignores the values of the headers cache-control: no-cache and cache-control: private. For example, a response that contains cache-control: no-cache="Set-Cookie" is treated as if the response contained Cache-Control: no-cache. By default, the response is not cached.
- An image (content-type = image/*) is always considered cacheable, even if an image response contains set-cookie or set-cookie2 headers, or if an image request contains a cookie header. The integrated cache removes set-cookie and set-cookie2 headers from a response before caching it. This diverges from RFC 2965. You can configure RFC-compliant behavior as follows:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add cache policy rfc_compliant_images_policy -rule "http.res.header.set
    -cookie2.exists || http.res.header.set-cookie.exists" -action
    NOCACHE

bind cache global rfc_compliant_images_policy -priority 100 -type REQ\
    _OVERRIDE
```

- The following cache-control headers in a request force an RFC-compliant cache to reload a cached response from the origin server:

`Cache-control: max-age=0`

`Cache-control: no-cache`

To guard against denial-of-service attacks, this behavior is not the default.

- By default, the caching module considers a response to be cacheable unless a response header state otherwise. To make this behavior RFC 2616 compliant, set `-weakPosRelExpiry` and `-weakNegResExpiry` to 0 for all content groups.

Remove cookies from a response

Cookies are often personalized for a user, and typically should not be cached. The `Remove Response Cookies` parameter removes `Set-Cookie and Set-Cookie2` headers before caching a response. By default, the `Remove Response Cookies` option for a content group prevents caching of responses with `Set-Cookie` or `Set-Cookie2` headers.

> **Note:**
> When images are cached, the built-in behavior is to remove the `Set-Cookie` and `Set-Cookie2` headers before caching, no matter how the content group is configured.
>
> Citrix recommends that you accept the default `Remove Response Cookies` for every content group that stores embedded responses, for example, images.

To configure `Remove Response Cookies` for a content group by using the command line interface:

At the command prompt, type:

`set cache contentgroup <name> -removeCookies YES`

Configure Remove Response Cookies for a content group by using Citrix ADC GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On the **Others** tab, in the **Settings** group, select Remove response cookies option.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Inserting HTTP headers at response time

The integrated cache can insert HTTP headers in responses that result from cache requests. The Citrix ADC appliance does not alter headers in responses that result from cache misses.

The following table describes headers that you can insert in a response.

Header	Specification
Age	Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.
via	Lists protocols and recipients between the start and end points for a request or a response. The Citrix ADC appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is `NS-CACHE-10.0`: last octet of the Citrix ADC IP address."For more information, see "Configuring Global Attributes for Caching."

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Header	Specification
Tag	The cache supports response validation using Last-Modified and Tag headers to determine if a response is stale. The cache inserts an Tag in a response only if it caches the response and the origin server has not inserted its own Tag header. The Tag value is an arbitrary unique number. The Tag value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With Tag header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an Tag header and replace the origin-provided Cache-Control header.
Cache-Control	The Citrix ADC appliance typically does not modify cacheability headers in responses that is serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the Citrix ADC appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Header	Specification
Age	Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.
via	Lists protocols and recipients between the start and end points for a request or a response. The Citrix ADC appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is "NS-CACHE-9.2: last octet of the Citrix ADC IP address."For more information, see "Configuring Global Attributes for Caching."
Tag	The cache supports response validation using the Last-Modified and Tag headers to determine if a response is stale. The cache inserts an Tag in a response only if it caches the response and the origin server has not inserted its own Tag header. The Tag value is an arbitrary unique number. The Tag value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With Tag header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an Tag header and replace the origin-provided Cache-Control header.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Header	Specification
Cache-Control	The Citrix ADC appliance typically does not modify cacheability headers in responses that is serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the Citrix ADC appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache.

Insert an age, via, or Tag header

The following procedures describe how to insert Age, Via, and ETag headers.

Insert an Age, Via, or Etag header by using the Citrix ADC command interface:

At the command prompt, type:

```
set cache contentgroup <name> -insertVia YES -insertAge YES -insertETag
 YES
```

Configure the Age, Via, or Etag header by using the Citrix ADC GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups,** and select the **content group**.
2. On the **Others** tab, in the HTTP Header Insertions group, select the **Via**, **Age**, or **ETag** options, as appropriate.
3. The values for the other header types are calculated automatically. You configure the Via value in the main settings for the cache.

Insert a cache-control header

When the integrated cache replaces a Cache-Control header that the origin server inserted, it also replaces the Expires header. The new Expires header contains an expiration time in the past. This ensures that HTTP/1.0 clients and caches (that do not understand the Cache-Control header) do not cache the content.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Insert a cache-control header by using the Citrix ADC command interface

At the command prompt, type:

```
set cache contentgroup <name> -cacheControl <value>
```

Insert a cache-control header by using the Citrix ADC GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and
    a) Click **Expiry Method** to clear the heuristic and default expiry settings and set the relevant value in the Expire content after text box.
    b) Click **Others** tab and type the header you want to insert in the Cache-Control text box. Alternatively, click Configure to set the Cache-Control directives in cached responses.

Ignore cache-control and pragma headers in requests

By default, the caching module processes Cache-Control and Pragma headers. The following tokens in the Cache-Control headers are processed as described in RFC 2616.

- max-age
- max-stale
- only-if-cached
- no-cache

A Pragma: no-cache header in a request is treated in the same way as a Cache-Control: no-cache header.

If you configure the caching module to ignore the Cache-Control and Pragma headers, a request that contains a Cache-Control: No-Cache header causes the Citrix ADC appliance to retrieve the response from the origin server, but the cached response is not updated. If the caching module processes Cache-Control and Pragma headers, the cached response is refreshed.

The following table summarizes the implications of various settings for these headers and the Ignore Browser's Reload Request setting.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Setting for Ignore Cache-Control and Pragma Headers	Setting for Ignore Browser's Reload Request	Outcome
Yes	Yes or No	Ignore the Cache-Control and Pragma headers from the client, including the Cache-Control: no-cache directive.
No	Yes	The Cache-Control: no-cache header produces a cache miss, but a response that is already in the cache is not refreshed.
No	No	A request that contains a Cache-Control: no-cache header causes a cache miss and the stored response is refreshed.

To ignore Cache-Control and Pragma headers in a request by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReqCachingHdrs YES
```

To ignore browser reload requests by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReloadReq NO
```

> **Note:**
> By default, the -ignoreReloadReq parameter is set to YES.

Ignore Cache-Control and Pragma headers in a request by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On the **Others** tab, in the **Settings** group, select **Ignore Cache-control and Pragma Headers** in **Requests** option.

Example of a policy to ignore Cache-Control headers:

In the following example, you configure a request-time override policy to cache responses that contain Content-type: image/* regardless of the Cache-Control header in the response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure a request-time override policy to cache all responses with image/*

Flush the cache using the Invalidate All option.

Configure a new cache policy, and direct the policy to a particular content group. For more information, see "Configuring a Policy in the Integrated Cache."

Ensure the content group that the policy uses is configured to ignore Cache-Control headers, as described in "Ignoring Cache-Control and Pragma Headers in Requests."

Bind the policy to the request-time override policy bank.

For more information, see Globally Binding an Integrated Caching Policy topic.

Poll origin server every time a request is received

You can configure the Citrix ADC appliance to always consult the origin server before serving a stored response. This is known as Poll Every Time (PET). When the Citrix ADC appliance consults the origin server and the PET response has not expired, a full response from the origin server does not overwrite cached content. This property is useful when serving client-specific content.

After a PET response expires, the Citrix ADC appliance refreshes it when the first full response arrives from the origin server.

The Poll Every Time (PET) function works as follows:

For a cached response that has validators in the form of a Tag or a Last-Modified header, if the response expires it is automatically marked PET and cached.

You can configure PET for a content group.

If you configure a content group as PET, every response in the content group is marked PET. The PET content group can store responses that do not have validators. Responses that are automatically marked PET are always expired. Responses that belong to a PET content group can expire after a delay, based on how you configure the content group.

Two types of requests are affected by polling:

- Conditional Requests: A client issues a conditional request to ensure that the response that it has is the most recent copy. A user-agent request for a cached PET response is always converted to a conditional request and sent to the origin server. A conditional request has validators in If-Modified-Since or If-None-Match headers. The If-Modified-Since header contains the time from the Last-Modified header. An If-None-Match header contains the response's Tag header value. If the client's copy of the response is fresh, the origin server replies with 304 Not Modified. If the copy is stale, a conditional response generates a 200 OK that contains the entire response.
- Non-Conditional Requests: A non-conditional request can only generate a 200 OK that contains the entire response.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Origin Server Response	Action
Send the full response	The origin server sends the response as-is to the client. If the cached response has expired, it is refreshed.
304 Not Modified	The following header values in the 304 response are merged with the cached response and the cached response is served to the client: Date, Expires, Age, Cache-Control header Max-Age, and S-Maxage tokens
401 Unauthorized; 400 Bad Request; 405 Method Not Allowed; 406 Not Acceptable; 407 Proxy Authentication Required	The origin's response is served as-is to the client. The cached response is not changed.
Any other error response, for example, 404 Not Found	The origin's response is served as-is to the client. The cached response is removed.

> **Note:**
> The Poll Every Time parameter treats the affected responses as non-storable.

To configure poll every time by using the command line interface

At the command prompt, type:

```
add cache contentgroup <contentGroupName> -pollEveryTime YES
```

Poll by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Content Groups**, and select the content group.
2. On the **Others** tab, in the Settings group, select Poll every time (validate cached content with origin for every request) option.

PET and client-specific content

The PET function can ensure that content is customized for a client. For example, a website that serves content in multiple languages examines the Accept-Language request header to select the language for the content that it is serving. For a multi-language website where English is the predominant language, all English language content can be cached in a PET content group. This ensures that every request goes to the origin server to determine the language for the response. If the response is English, and the content has not changed, the origin server can serve a 304 Not Modified to the cache.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following example shows commands to cache English responses in a PET content group, configure a named expression that identifies English responses in the cache, and configure a policy that uses this content group and named expression. Bold is used for emphasis:

```
add cache contentgroup EnglishLanguageGroup -pollEveryTime YES
add expression containsENExpression  – rule "http.res.header(\\"Content-
    Language\\").contains(\\"en\\")"
add cache policy englishPolicy -rule containsENExpression -action CACHE
     -storeInGroup englishLanguageGroup
bind cache policy englishPolicy -priority 100 -precedeDefRules NO
```

PET and authentication, authorization, and auditing

Outlook Web Access (OWA) is a good example of dynamically generated content that benefits from PET. All mail responses (*.EML objects) have an ETag validator that enables them to be stored as PET responses.

Every request for a mail response travels to the origin server, even if the response is cached. The origin server determines whether the requestor is authenticated and authorized. It also verifies that the response exists in the origin server. If all results are positive, the origin server sends a 304 Not Modified response.

Configure integrated cache as a forward proxy

September 14, 2021

The integrated cache can service as a forward proxy device that passes requests to other Citrix ADC appliances or to other types of cache servers. You configure the integrated cache as a forward proxy by identifying the IP addresses of the cache server or servers. After configuring the forward proxy, the Citrix ADC appliance sends requests that contain the configured IP address on to the cache server instead of involving the integrated cache.

To configure the Citrix ADC as a forward cache proxy by using the command line interface

At the command prompt, type:

```
add cache forwardProxy <IPAddress> <port>
```

To configure the Citrix ADC as a forward cache proxy by using the GUI

1. Navigate to **Optimization** > **Integrated Caching** > **Forward Proxy**, and add a forward proxy by specifying the IP address and port number.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Default settings for the integrated cache

September 14, 2021

The Citrix ADC integrated cache feature provides built-in policies with default settings and initial settings for the Default content group. The information in this section defines the parameters for the built-in policies and Default content group.

Default caching policies

The integrated cache has built-in policies. The Citrix ADC appliance evaluates the policies in a particular order, as discussed in the following sections.

You can override these built-in policies with a user-defined policy that is bound to a request-time override or response-time override policy bank.

> **Note**
> If you configured policies prior to release 9.0 and specified the -precedeDefRules parameter when binding the policies, they are automatically assigned to override-time bind points during migration.

View default policies

The built-in policy names start with an underscore (_). You can view the built-in policies from the command line and the administrative console using the show cache policy command.

Default request policies

You can override the following built-in request time policies by configuring new policies and binding them to the request-time override processing point. In the following policies, note that the MAY_NOCACHE action stipulates that the transaction is cached only when there is a user-configured or built-in CACHE directive at response time.

The following policies are bound to the _reqBuiltinDefaults policy label. They are listed in priority order.

Do not cache a response for a request that uses any method other than GET.

The policy name is _nonGetReq. The following is the policy rule:

```
!HTTP.REQ.METHOD.eq(GET)
```

Set a NOCACHE action for a request with header value that contains If-Match or If-Unmodified-Since.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The policy name is _advancedConditionalReq. The following is the policy rule:

```
HTTP.REQ.HEADER("If-Match").EXISTS || HTTP.REQ.HEADER("If-Unmodified-Since").EXISTS
```

Set a MAY_NOCACHE action for a request with the following header values: Cookie, Authorization, Proxy-authorization, or a request which contains the NTLM or Negotiate header.

The policy name is _personalizedReq. The following is the policy rule:

```
HTTP.REQ.HEADER("Cookie").EXISTS || HTTP.REQ.HEADER("Authorization").EXISTS || HTTP.REQ.HEADER("Proxy-Authorization").EXISTS || HTTP.REQ.IS_NTLM_OR_NEGOTIATE
```

Default response policies

You can override the following default response-time policies by configuring new policies and binding them to the response-time override processing point.

The following policies are bound to the **_resBuiltinDefaults** policy label and are evaluated in the order in which they are listed:

1. Do not cache HTTP responses unless they are of type 200, 304, 307, 203 or if the types are between 400 and 499 or between 300 and 302.

   The policy name is **_uncacheableStatusRes**. The following is the policy rule:

   ```
   !((HTTP.RES.STATUS.EQ(200))|| (HTTP.RES.STATUS.EQ(304))|| (HTTP.RES.STATUS.BETWEEN(400,499))|| (HTTP.RES.STATUS.BETWEEN(300, 302))|| (HTTP.RES.STATUS.EQ(307))|| (HTTP.RES.STATUS.EQ(203)))
   ```

2. Do not cache an HTTP response if it has a Vary header with a value of anything other than Accept-Encoding.

   The compression module inserts the Vary: Accept_Encoding header. The name of this expression is **_uncacheableVaryRes**. The following is the policy rule:

   ```
   ((HTTP.RES.HEADER("Vary").EXISTS)&& ((HTTP.RES.HEADER("Vary").INSTANCE(1).LENGTH > 0)|| (!HTTP.RES.HEADER("Vary").STRIP_END\\_WS.SET_TEXT_MODE(IGNORECASE).eq("Accept-Encoding"))))
   ```

3. Do not cache a response if its Cache-Control header value is No-Cache, No-Store, or Private, or if the Cache-Control header is not valid.

   The policy name is **_uncacheableCacheControlRes**. The following is the policy rule:

   ```
   ((HTTP.RES.CACHE\\_CONTROL.IS\\_PRIVATE)|| (HTTP.RES.CACHE\\_CONTROL.IS\\_NO\\_CACHE)|| (HTTP.RES.CACHE\\_CONTROL.IS\\_NO\\_STORE)|| (HTTP.RES.CACHE\\_CONTROL.IS\\_INVALID))
   ```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. Cache responses if the Cache-Control header has one of the following values: Public, Must-Revalidate, Proxy-Revalidate, Max-Age, S-Maxage.

   The policy name is **_cacheableCacheControlRes**. The following is the policy rule:

   ```
   ((HTTP.RES.CACHE_CONTROL.IS_PUBLIC)|| (HTTP.RES.CACHE_CONTROL.
   IS_MAX_AGE)|| (HTTP.RES.CACHE_CONTROL.IS_MUST_REVALIDATE)|| (HTTP
   .RES.CACHE_CONTROL.IS_PROXY_REVALIDATE)|| (HTTP.RES.CACHE_CONTROL
   .IS_S_MAXAGE))
   ```

5. Do not cache responses that contain a Pragma header.

   The name of the policy is **_uncacheablePragmaRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Pragma").EXISTS
   ```

6. Cache responses that contain an Expires header.

   The name of the policy is **_cacheableExpiryRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Expires").EXISTS
   ```

7. If the response contains a Content-Type header with a value of Image, remove any cookies in the header and cache it.

   The name of the policy is **_imageRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).STARTSWITH
   ("image/")
   ```

   You can configure the following content group to work with this policy:

   ```
   add cache contentgroup nocookie -group -removeCookies YES
   ```

8. Do not cache a response that contains a Set-Cookie header.

   The name of the policy is **_ personalizedRes**. The following is the policy rule:

HTTP.RES.HEADER(“Set-Cookie”).EXISTS

Restrictions on default policies

You cannot override the following built-in request time policies with user-defined policies.

These policies are listed in priority order.

1. Do not cache any responses if the corresponding HTTP request lacks a GET or POST method.
2. Do not cache any responses for a request if the HTTP request URL length plus host name exceeds 1744 byes.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. Do not cache a response for a request that contains an If-Match header.
4. Do not cache a request that contains an If-Unmodified-Since header.

> **Note**
> This is different from the If-Modified-Since header.

1. Do not cache a response if the server does not set an expiry header.

You cannot override the following built-in response time policies. These policies are evaluated in the order in which they are listed:

1. Do not cache responses that have an HTTP response status code of 201, 202, 204, 205, or 206.
2. Do not cache responses that have an HTTP response status code of 4xx, with the exceptions of status codes 403, 404, and 410.
3. Do not cache responses if the response type is FIN terminated, or the response does not have one of the following attributes: Content-Length, or Transfer-Encoding: Chunked.
4. Do not cache the response if the caching module cannot parse its Cache-Control header.

Initial settings for the default content group

When you first enable integrated caching, the Citrix ADC appliance provides one predefined content group named the Default content group. For detailed information, see Default content group settings table.

Troubleshooting

September 14, 2021

If the integrated cache feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for troubleshooting

For more information about the resources available for troubleshooting and sample configurations, see Resource for troubleshooting PDF file.

Front end optimization

September 14, 2021

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:** Front end optimization is available if you have an Advanced or Premium Citrix ADC license and are running Citrix ADC release 10.5 or later.

The HTTP protocols that underlie web applications were originally developed to support the transmission and rendering of simple webpages. New technologies such as JavaScript and cascading style sheets (CSS), and new media types such as Flash videos and graphics-rich images, place heavy demands on front-end performance, that is, on performance at the browser level.

The Citrix ADC front end optimization (FEO) feature addresses such issues and reduces the load time and render time of webpages by:

- Reducing the number of requests.
- Required for rendering each page.
- Reducing the number of bytes in page responses.

Simplifying and optimizing the content served to the client browser.

You can customize your FEO configuration to provide the best results for your users. Citrix ADCs support numerous web content optimizations for both desktop and mobile users. The following tables describe the front-end optimizations provided by the FEO feature, and the operations performed on different types of files.

Optimizations performed by the FEO feature

Web Optimization	Problem	What Citrix ADC FEO feature does	Benefits
Inlining	Client browsers often send multiple requests to servers for loading external CSS, images, and JavaScript associated with the webpage.	CSS inline, JavaScript inline, CSS combine	Loading the external CSS, images, and JavaScript inline with the HTML files improves page-rendering time. This optimization is beneficial for content that is viewed only once, and for mobile devices that have limited cache sizes.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Web Optimization	Problem	What Citrix ADC FEO feature does	Benefits
Minification	Data fetched from servers includes inessential characters such as white spaces, comments, and newline characters. The time that browsers spend in processing such data creates website latency.	CSS minification, JavaScript minification, Removal of HTML comments	Minified files consume less bandwidth and avoid the latency caused by special processing.
Image optimization	Mobile browsers often have slow connection speeds and limited cache memory. Downloading the images on mobile clients consumes more bandwidth, processing time, and cache space, resulting in website latency.	JPEG optimization, CSS image inlining, **Image shrink-to** attributes, GIF to PNG conversion, HTML image inlining, WebP image conversion, JPEG, GIF, PNG to JPEG-XR image conversion	Reduces the image to the size indicated in the image tag by Citrix ADC, enabling client browsers to load images faster.
Repositioning	Inefficient processing of external CSS, images, and JavaScript increases page-load time.	Image lazy loading, CSS move to Head, JavaScript move to end	Repositions HTML elements, to reduce rendering time for webpages and enable client browsers to load the objects faster.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Web Optimization	Problem	What Citrix ADC FEO feature does	Benefits
Connection Management	Many browsers set limits on the number of simultaneous connections that can be established to a single domain. This can cause browsers to download webpage resources one at a time, resulting in higher browsers time.	Domain sharding	Overcomes the connection limitation, which improves page-rendering time by enabling client browsers to download more resources in parallel.

Web Optimizations on different file types:

Citrix ADC can perform web optimizations on CSS, images, Javascript, and HTML. For more information, see Web Optimizations PDF.

> **Note:**
> The front end optimization feature supports ASCII characters only. It does not support the Unicode character set.

How front end optimization works

After the Citrix ADC receives the response from the server:

1. Parses the contents of the page, creates an entry in the cache (wherever applicable), and applies the FEO policy.

   For example, a Citrix ADC can apply the following optimization rules:

   - Remove white spaces or comments present within a CSS or JavaScript.
   - Combine one or more CSS files to one file.
   - Convert GIF image format to PNG format.

2. Rewrites the embedded objects and saves the optimized content in the cache, with a different signature than the one used for the initial cache entry.
3. For subsequent requests, fetches the optimized objects from the cache, not from the server, and forwards the responses to the client.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

**

Remove extraneous information such as white spaces and comments.

The period during which the browser can use the cached resource without checking to see if fresh content is available on the server.

Configure front end optimization

Optionally, you can change the values of the front end optimization global settings. Otherwise, begin by creating actions that specify the optimization rules to be applied to the embedded objects.

After configuring actions, create policies, each with a rule specifying a type of request for which to optimize the response, and associate the actions with the policies.

> **Note:** The Citrix ADC evaluates front end optimization policies at request time only, not at response time.

To put the policies into effect, bind them to bind points. You can bind a policy globally, so that it applies to all traffic that flows through the Citrix ADC, or you can bind the policy to a load balancing or content switching virtual server of type HTTP or SSL. When you bind a policy, assign it a priority. A lower priority number indicates a higher value. The Citrix ADC applies the policies in the order of their priorities.

Prerequisites

Front end optimization requires the Citrix ADC integrated caching feature to be enabled. Also, you must perform the following integrated caching configurations:

- Allocate cache memory.
- Set the maximum response size and memory limit for a default cache content group.

For more information on configuring integrated caching, see Integrated Caching.

Note: The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

Configure front end optimization by using Citrix ADC command interface

At the command prompt, do the following:

1. Enable the front end optimization feature.

```
enable ns feature FEO
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. Create one or more front end optimization actions.

```
add feo action <name> [-imgShrinkToAttrib] [-imgGifToPng] ...
```

Example: To add a front end optimization action for converting images in GIF format to PNG format and to extend the cache expiry period:

```
add feo action allact -imgGifToPng -pageExtendCache
```

1. [Optional] Specify non-default values for front end optimization global settings.

```
set feo parameter [-cacheMaxage <integer>] [-JpegQualityPercent
<integer>] [-cssInlineThresSize <integer>] [-inlineJsThresSize <
integer> [-inlineImgThresSize <integer>]
```

Example: To specify the cache maximum expiry period:

```
set feo parameter -cacheMaxage 10
```

1. Create one or more front end optimization policies.

```
add feo policy <name> <rule> <action>
```

Example: To add a front end optimization policy and associate it with the above specified allact action:

```
1 >add feo policy pol1 TRUE all act
2 >add feo policy pol1 "(HTTP.REQ.URL.CONTAINS(\"testsite\"))" allact1
```

1. Bind the policy to a load balancing or content switching virtual server, or bind it globally.

```
bind lb vserver <name> -policyName <string> -priority <num>
```

```
bind cs vserver <name> -policyName <string> -priority <num>
```

```
bind feo global <policyName> <priority> -type <type> <gotoPriorityExpression
>
```

Example: To apply the front end optimization policy to a virtual server named “abc”:

```
> bind lb vserver abc -policyName pol1 -priority 1 -type NONE
```

Example: To apply the front end optimization policy for all the traffic reaching the ADC:

```
> bind feo global pol1 100 -type REQ_DEFAULT
```

1. Save the configuration. save ns config

Configure front end optimization by using the GUI

1. Navigate to **Optimization** > **Front End Optimization** > **Actions**, and click **Add** and create a front end optimization action by specifying the relevant details.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. [Optional] Specify the front end optimization global settings.
3. Navigate to **Optimization** > **Front End Optimization**, and on the right-pane, under Settings, click **Change Front End Optimization** settings and specify the front end optimization global settings.
4. Create a front end optimization policy.
5. Navigate to **Optimization** > **Front End Optimization** > **Policies**, click **Add** and create a front end optimization policy by specifying the relevant details.
6. Bind the policy to a load balancing or content switching virtual server.

    a) Navigate to **Optimization** > **Front End optimization** > **Policies**.
    b) Select a front end optimization policy and click **Policy Manager**.
    c) Under **Front End Optimization Policy Manager**, bind the front end optimization policy to a load balancing or content switching virtual server.

Verify front end optimization configuration

The dashboard utility displays summary and detailed statistics in tabular and graphic formats. You can view the FEO statistics to evaluate your FEO configuration.

Optionally, you can also display statistics for an FEO policy, including the number of select that the policy counter increments during the policy based FEO.

> **Note:**
> For more information about statistics and charts, see the Dashboard help on the Citrix ADC appliance.

View FEO statistics by using the CLI

At the command prompt, type the following commands to display a summary of FEO statistics, FEO policy select and details, and detailed FEO statistics, respectively:

- `stat feo` Note: The stat feo policy command displays statistics only for advanced FEO policies.
- `show feo policy name`
- `stat feo -detail`

View FEO statistics on Citrix ADC dashboard

In the dashboard GUI, you can:

- Select Front End Optimization to display a summary of FEO statistics.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Click the **Graphical View** tab to display the rate of requests processed by the FEO feature.

Sample optimization:

Refer to the Sample PDF for some examples of content optimization actions that are applied on HTML content and the embedded objects within the HTML content.

Media classification

September 14, 2021

Understanding the type of traffic in the network helps network administrators to manage bandwidth consumption for optimal network performance. The media classification mode monitors and displays the statistics of media traffic going through the Citrix ADC appliance.

With this mode enabled, a network administrator can collect stats showing the amount of data accessed, and the types of devices from which the media files have been accessed. The Citrix ADC appliance also supports byte-range requests in this mode.

Currently the Citrix ADC appliance can monitor and display statistics for the following media file types:

Media	File type
Microsoft Smooth Streaming	Video
Apple Live Streaming	Video
Audio Data Transport Stream (ADTS)	Audio
Advanced Audio Coding (AAC)	Audio
Flash Video (FLV)	Audio and Video
3GP	Audio and Video

The appliance can display stats for the following devices:

Device Platform	Device Type
iOS	iPad and iPod
Android	Mobiles and tablets
Laptop or Desktop	Windows laptop and desktop computers

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Device Platform	Device Type
Others	Other mobile devices (mobiles and tablets)

The network administrators can check the following stats counters to know the amount of data accessed through the Citrix ADC appliance for various media traffic types.

Media File Name	Stats Counter
Microsoft Smooth Streaming	`mcmssmthstrmvid`—This counter records the total number of Microsoft Smooth Streaming videos served by the Citrix ADC appliance; `Mcmssmthstrvidpl`—This counter records the total number of Microsoft Smooth Streaming video playlists served by the Citrix ADC appliance; `Mcmssmthstrmvidbytes`—This counter records the total number of data bytes served for Microsoft Smooth Streaming media traffic on the Citrix ADC appliance; `Mcmssmthstrmplvidbytespl`—This counter records the total number of Microsoft Smooth Streaming playlist bytes served by the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Media File Name	Stats Counter
Apple Live Streaming	mccaplelivestrmngvid—This counter records the total number of Apple Live Streaming videos served by the Citrix ADC appliance. Mccapplelivestrmngvidpl—This counter records the total number of Apple Live Streaming video playlists served by the Citrix ADC appliance. Mcapplelivestreamingvidbytes—This counter records the total number of data bytes served for Apple Live Streaming media traffic on the Citrix ADC appliance. Mcapplelivestreamingplaylistvidbytespl—This counter records the total number of Apple Live Playlist bytes served by the Citrix ADC appliance.
Audio Data Transport Stream (ADTS)	mcadtsaudio—This counter records the total number of ADTS audio clips served by the Citrix ADC appliance. Mcadtsaudiobytes—This counter records the total number of data bytes served for ADTS media traffic on the Citrix ADC appliance.
Advanced Audio Coding (AAC)	Mcaacaudio—This counter records the total number of AAC audio clips served by the Citrix ADC appliance. Mcaacaudiobytes—This counter records the total number of data bytes served for AAC media traffic on the Citrix ADC appliance.
Flash Video (FLV)	Mcflvvid—This counter records the total number of flash videos served by the Citrix ADC appliance. Mcflvvidbytes—This counter records the total number of data bytes served for flash videos on the Citrix ADC appliance.
3GP	mc3gpvidbytes—This counter records the total number of data bytes served for 3GP media traffic on the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The Citrix ADC appliance detects media file types by their signatures in the *initial body bytes* of the responses. For example, the initial body bytes for an mp4 file have the following signature in the response:

```
**....ftypmp42** ....isommp42....moov...lmvhd.....c.\!.c.\!..
```

The Citrix ADC appliance detects the client device type by the *user agent string* that the client device includes in the HTTP GET request. For example, a window phone using a UC browser has the following user agent string in the HTTP GET request:

```
User-Agent: **UCWEB**/2.0 (**Windows**; U; wds 8.10; en-US; HTC; 8X
by HTC)U2/1.0.0
```

Enable media classification

By default, media classification is disabled on the Citrix ADC appliance. You have to enable the mode before using it.

To enable media classification by using the command line interface

At the command prompt, type:

```
enable ns mode Mediaclassification
```

To enable media classification by using the GUI

Enable media classification on Citrix ADC appliance

Navigate to **System** > **Settings** > **Configure Modes** and select **Media Classification**.

To view media traffic statistics on the Citrix ADC appliance

Navigate to **Optimization** and click **Media Classification** to view the media traffic statistics.

Verify media classification statistics

You can view the media traffic statistics in the dashboard utility or using the command line interface. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

> **Note**
> For more information about statistics and charts, see the Dashboard help on your Citrix ADC appliance.

To View media classification statistics by using the command line interface

At the command prompt, type one of the following commands to display a summary of media classification statistics, display detailed statistics, or clear the display:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
stat Mediaclassification

stat Mediaclassification -detail

stat Mediaclassification -clearstats
```

To view Media Classification statistics on the Dashboard

In the **Dashboard** utility, you can display the following types of media classification statistics:

1. Select **Media Classification** to display a summary of the media traffic statistics.
2. To display detailed media traffic statistics, click the **Details**.
3. To clear the media traffic statistics, click **Clear**.

Reputation

September 14, 2021

Citrix offers reputation based security. Using reputation assessment to determine the risk of processing requests, you can take actions such as blocking or dropping certain requests to improve the performance of your application.

The Citrix ADC IP reputation feature uses IP reputation checks to prevent Zero day attacks and provide protection against malicious sources associated with web attacks, phishing activity, or web scanning.

For more details, see IP Reputation.

IP Reputation

October 30, 2023

IP reputation is a tool that identifies IP addresses that send unwanted requests. Using the IP reputation list you can reject requests that are coming from an IP address with a bad reputation. Optimize Web Application Firewall performance by filtering requests that you do not want to process. Reset, drop a request, or even configure a responder policy to take a specific responder action.

The following are some attacks that you can prevent by using IP Reputation:

- **Virus Infected personal computers**. (home PCs) are the single biggest source of Spam on the internet. IP Reputation can identify the IP address that is sending unwanted requests. IP reputation can be especially useful for blocking large scale DDoS, DoS, or anomalous SYN flood attacks from known infected sources.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **Centrally managed and automated botnet**. Attackers have gained popularity for stealing passwords, because it doesn't take long when hundreds of computers work together to crack your password. It is easy to launch botnet attacks to figure out passwords that use commonly used dictionary words.
- **Compromised web-server**. Attacks are not as common because awareness and server security have increased, so hackers and spammers look for easier targets. There are still web servers and online forms that hackers can compromise and use to send spam (such as viruses and porn). Such activity is easier to detect and quickly shut down, or block with a reputation list such as SpamRats.
- **Windows Exploits**. (such as Active IPs offering or distributing malware, shell code, rootkits, worms, or viruses).
- **Known spammers and hackers**.
- **Mass e-mail marketing campaigns**.
- **Phishing Proxies** (IP addresses hosting phishing sites, and other fraud such as ad click fraud or gaming fraud).
- **Anonymous proxies** (IPs providing proxy and anonymization services including The Onion Router aka TOR).

A Citrix ADC appliance uses **Webroot** as the service provider for a dynamically generated malicious IP database and the metadata for those IP addresses. Metadata might include geolocation details, threat category, threat count, and so on. The Webroot threat Intelligence engine receives real-time data from millions of sensors. It automatically and continuously captures, scans, analyses and scores the data, using advanced machine learning and behavioral analysis. Intelligence about a threat is continually updated.

The Citrix ADC appliance validates an incoming request for its bad reputation using the Webroot's uses IP reputation database. The database has a huge collection of IP address classified based IP threat categories. Following are the IP threat categories and its description.

- Spam Sources. Spam Sources includes Tunneling Spam messages through proxy, anomalous SMTP activities, Forum Spam activities.
- Windows Exploits. The Windows Exploits category includes active IP Address offering or distributing malware, shell code, rootkits, worms, or viruses
- Web Attacks. The Web Attacks category includes cross site scripting, iFrame injection, SQL injection, cross domain injection, or domain password brute force attack
- Botnets. The Botnet category includes Botnet C&C channels, and infected zombie machine controlled by Bot master
- Scanners. The Scanners category includes all reconnaissance such as probes, host scan, domain scan and password brute force attack
- Denial of Service. The Denial of Services category includes DOS, DDOS, anomalous sync flood, anomalous traffic detection

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Reputation. Deny access from IP addresses currently known to be infected with malware. This category also includes IPs with average low Webroot Reputation Index score. Enabling this category prevents access from sources identified to contact malware distribution points.
- Phishing. The Phishing category includes IP addresses hosting phishing sites, other kinds of fraud activities such as Ad Click Fraud or Gaming fraud
- Proxy. The Proxy category includes IP addresses providing proxy and def services.
- Mobile Threats. The Mobile Threats category includes IP addresses of malicious and unwanted mobile applications. This category leverages data from the Webroot mobile threat research team.
- Tor Proxy. The Tor Proxy category includes IP addresses acting as exit nodes for the Tor Network. Exit nodes are the last point along the proxy chain and make a direct connection to the originator's intended destination.

When a threat is detected anywhere in the network, the IP address is flagged as malicious and all appliances connected to the network are immediately protected. The dynamic changes in the IP addresses are processed with high speed and accuracy by using advanced machine learning.

As stated in the data sheet from Webroot, the Webroot's sensor network identifies many key IP threat types, including spam sources, Windows exploits, botnets, scanners, and others. (See the flow diagram on the data sheet.)

The Citrix ADC appliance uses an `iprep` client process to get the database from Webroot. The `iprep` client uses the HTTP GET method to get the absolute IP list from Webroot for the first time. Later, it checks delta changes once every 5 minutes.

> **Important:**
>
> - Make sure that the Citrix ADC appliance has Internet access and DNS is configured before you use the IP Reputation feature.
> - To access the Webroot database, the Citrix ADC appliance must be able to connect to **api.bcti.brightcloud.com** on **port 443**. Each node in the HA or cluster deployment gets the database from Webroot and must be able to access this Fully Qualified Domain Name (FQDN).
> - Webroot hosts its reputation database in AWS currently. Therefore, Citrix ADC must be able to resolve AWS domains for downloading the reputation db. Also, the firewall must be open for AWS domains.
>
> **Note:**
>
> Each packet engine requires at least 4 GB to function properly when the IP Reputation feature is enabled.

Advanced policy Expressions. Configure the IP Reputation feature by using advanced policy expres-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

sions (default syntax expressions) in the policies bound to supported modules, such as Web Application Firewall and responder. The following are two examples showing expressions that can be used to detect whether the client IP address is malicious.

1. **CLIENT.IP.SRC.IPREP_IS_MALICIOUS**: This expression evaluates to TRUE if the client is included in the malicious IP list.
2. **CLIENT.IP.SRC.IPREP_THREAT_CATEGORY (CATEGORY)**: This expression evaluates to TRUE if the client IP is malicious IP and is in the specified threat category.

Following are the possible values for the threat category:

SPAM_SOURCES, WINDOWS_EXPLOITS, WEB_ATTACKS, BOTNETS, SCANNERS, DOS, REPUTATION, PHISHING, PROXY, NETWORK, CLOUD_PROVIDERS, MOBILE_THREATS, TOR_PROXY.

> **Note:**
>
> The IP reputation feature checks both source and destination IP addresses. It detects malicious IPs in the header. If the PI Expression in a policy can identify the IP address, the IP reputation check determines whether it is malicious.

IPRep log message. The `/var/log/iprep.log` file contains useful messages that capture information about communication with the Webroot database. The information can be about the credentials used during Webroot communication, failure to connect with Webroot, information included in an update (such as the number of IP addresses in the database).

Creating a blocklist or allowlist of IPs using a policy data set. You can maintain an allow list to allow access to specific IP addresses that are blocklisted in the Webroot database. You can also create a customized block list of IP addresses to supplement the Webroot reputation check. These lists can be created by using a policy **data set**. A data set is a specialized form of pattern set that is ideally suited for IPv4 address matching. To use data sets, first create the data set and bind IPv4 addresses to it. When configuring a policy for comparing a string in a packet, use an appropriate operator and pass the name of the pattern set or data set as an argument.

To create an allow list of addresses to treat as exceptions during IP reputation evaluation:

- Configure the policy so that the PI expression evaluates to False even if an address in the allow list is listed as malicious by Webroot (or any service provider).

Enabling or disabling IP reputation. IP reputation is a part of the general reputation feature, which is license based. When you enable or disable the reputation feature, it enables or disables IP Reputation.

General procedure. Deploying IP reputation involves the following tasks

- Verify that the license installed on the Citrix ADC appliance has IP reputation support. Premium and standalone application firewall licenses support the IP reputation feature.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Enable the IP reputation and application firewall features.
- Add an application firewall profile.
- Add an application firewall policy using the PI expressions to identify the malicious IP addresses in the IP Reputation database.
- Bind the application firewall policy to an appropriate bind point.
- Verify that any request received from a malicious address gets logged in the `ns.log` file to show that the request was processed as specified in the profile.

Configure the IP reputation feature using the CLI

At the command prompt, type:

- `enable feature reputation`
- `disable feature reputation`

The following examples show how you can add an application firewall policy using the PI expression to identify malicious addresses. You can use the built-in profiles, or add a profile, or configure an existing profile to invoke the desired action when a request matches a policy match.

Examples 3 and 4 show how to create a policy dataset to generate a block list or an allow list of IP addresses.

Example 1:

The following command creates a policy that identifies malicious IP addresses and block the request if a match is triggered:

```
add appfw policy pol1 CLIENT.IP.SRC.IPREP_IS_MALICIOUS APPFW_BLOCK
```

Example 2:

The following command creates a policy that uses the reputation service to check the client IP address in the `X-Forwarded-For` header and reset the connection if a match is triggered.

```
> add appfw policy pol1 "HTTP.REQ.HEADER(\"X-Forwarded-For\").TYPECAST_IP_ADDR
.IPREP_IS_MALICIOUS"APPFW_RESET**
```

Example 3:

The following example shows how to add a list to add exceptions that allow specified IP addresses:

```
> add policy dataset Allow_list1 ipv4
> bind policy dataset Allow_list1 10.217.25.17 -index 1
> bind policy dataset Allow_list1 10.217.25.18 -index 2
```

Example 4:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The following example shows how to add the customized list to flag specified IP addresses as malicious:

```
> add policy dataset Block_list1 ipv4
> bind policy dataset Block_list1 10.217.31.48 -index 1
> bind policy dataset Block_list1 10.217.25.19 -index 2
```

Example 5:

The following example shows a policy expression to block the client IP in the following conditions:

- It matches an IP address configured in the customized Block_list1 (example 4)
- It matches an IP address listed in the Webroot database unless relaxed by inclusion in the Allow_list1 (example 3).

```
1 > add appfw policy "Ip_Rep_Policy" "((CLIENT.IP.SRC.IPREP_IS_MALICIOUS
     || CLIENT.IP.SRC.TYPECAST_TEXT_T.CONTAINS_ANY(\"Block_list1\")) && !
      (CLIENT.IP.SRC.TYPECAST_TEXT_T.CONTAINS_ANY(\"Allow_list1\")))"
     APPFW_BLOCK
```

Using Proxy server:

If the Citrix ADC appliance does not have direct access to the internet and is connected to a proxy, configure the IP Reputation client to send requests to the proxy.

At the command prompt, type:

```
set reputation settings –proxyServer <proxy server ip> -proxyPort <
proxy server port>
```

Example:

```
> set reputation settings proxyServer 10.102.30.112 proxyPort 3128
> set reputation settings –proxyServer testproxy.citrite.net –proxyPort
 3128
> unset reputation settings –proxyserver –proxyport
> sh reputation settings
```

> **Note:**
>
> The Proxy Server IP can be an IP address or a fully qualified domain name (FQDN).

Configure IP reputation by using the Citrix ADC GUI

1. Navigate to the **System > Settings**. In the **Modes and Features** section, click the link to access the **Configure Advanced Features** pane and enable the **Reputation** checkbox.
2. Click **OK**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To configure a proxy server by using the Citrix ADC GUI

1. On the configuration tab, navigate to **Security > Reputation**. Under **Settings**, click **Change Reputation Settings** to configure a proxy server. You can also enable or disable the reputation feature. **Proxy Server** can be an IP address or a fully qualified domain name (FQDN). **Proxy port** accepts values between [1–65535].

Create an allow list and a block list of client IP addresses using the GUI

1. On the **Configuration** tab, navigate to **AppExpert > Data Sets**.
2. Click **Add**.

- In the **Create Data Set** (or **Configure Data set**) pane, provide a meaningful name for the list of the IP addresses. The name must reflect the purpose of the list.
- Select **Type** as **IPv4**.
- Click **Insert** to add an entry.
- In the **Configure Policy dataset binding** pane, add an IPv4 format IP address in the Value input box.
- Provide an index.
- Add a comment that explains the purpose of the list. This step is optional, but is recommended because a descriptive comment is helpful in managing the list.

Similarly, you can create a block list and add the IP addresses that are to be considered malicious.

Also see, Pattern sets and data sets for more details regarding using data sets and configuring default syntax policy expressions.

Configure an application firewall policy by using the Citrix ADC GUI

1. On the **Configuration** tab, navigate to **Security > Application Firewall > Policies > Firewall**. Click **Add** to add a policy using the PI expression to use IP reputation.

You can also use the Expression editor to build your own policy expression. The list shows preconfigured options that are useful for configuring an expression using the threat categories.

Highlights

- Quickly and accurately stop bad traffic at the network's edge from known malicious IP addresses posing different types of threats. You can block the request without parsing the body.
- Dynamically configure IP reputation functionality for multiple applications.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Secure your network against data breach without a performance penalty, and consolidate protections onto a single service fabric using fast and easy deployments.
- You can do IP Reputation checks on source and destination IPs.
- You can also inspect the headers to detect malicious IPs.
- IP reputation check is supported in both forward proxy and reverse proxy deployments.
- The IP Reputation process connects with Webroot and updates the database every 5 minutes.
- Each node in the High Availability (HA) or Cluster deployment gets the database from Webroot.
- The IP reputation data is shared across all partitions in admin-partition deployments.
- You can use an AppExpert data set to create lists of IP addresses to add exceptions for IPs blocklisted in the Webroot database. You can also create your own customized block list to designate specific IPs as malicious.
- The iprep.db file is created in the `/var/nslog/iprep` folder. Once created, it is not deleted even if the feature is disabled.
- When the reputation feature is enabled, the Citrix ADC Webroot database is downloaded. After that, it is updated every 5 minutes.
- The Webroot database version is 1.
- The minor version gets updated every day. The update version is incremented after every 5 minutes and is reset back to 1 when the minor version is incremented.
- PI expressions enable you to use IP reputation with other features, such as responder and rewrite.
- The IP addresses in the database are in decimal notation.

Debugging tips

- If you cannot see the reputation feature in the GUI, verify that you have the right license.
- Monitor the messages in `var/log/iprep.log` for debugging.
- **Webroot connectivity**: If you see the `ns iprep: Not able to connect/resolve WebRoot` message, make sure that the appliance has internet access and DNS is configured.
- **Proxy server**: If you see the `ns iprep: iprep_curl_download: 88 curl_easy_perform failed. Error code: 5 Err msg:couldnt resolve proxy name` message, make sure that the proxy server configuration is accurate.
- **IP Reputation feature not working**: The IP Reputation process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.
- **Database download**: If the IP DB data download is failing after enabling the IP Reputation feature, the following error is seen in the logs.

```
iprep: iprep_curl_download:86 curl_easy_perform failed. Error code:7
Err msg:Couldn't connect to server
```

Solution: Allow the out-bound traffic to the following URLs or configure a proxy to resolve the issue.

```

SSL offload and acceleration

September 14, 2021

A Citrix ADC appliance configured for SSL acceleration transparently accelerates SSL transactions by offloading SSL processing from the server. To configure SSL offloading, you configure a virtual server to intercept and process SSL transactions, and send the decrypted traffic to the server (unless you configure end-to-end encryption, in which case the traffic is re-encrypted). Upon receiving the response from the server, the appliance completes the secure transaction with the client. From the client's perspective, the transaction seems to be directly with the server. A Citrix ADC configured for SSL acceleration also performs other configured functions, such as load balancing.

Configuring SSL offloading requires an SSL certificate and key pair, which you must obtain if you do not already have an SSL certificate. Other SSL-related tasks that you might need to perform include managing certificates, managing certificate revocation lists, configuring client authentication, and managing SSL actions and policies.

A non-FIPS Citrix ADC appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM).

All Citrix ADC appliances that do not support a FIPS card (including virtual appliances) support the Thales nShield® Connect and SafeNet external HSMs. (MPX 9700/10500/12500/15500 appliances do not support an external HSM.)

Note: FIPS-related options for some of the SSL configuration procedures described in this document are specific to a FIPS-enabled Citrix ADC appliance.

SSL offloading configuration

February 28, 2022

To configure SSL offloading, you must enable SSL processing on the Citrix ADC appliance and configure an SSL based virtual server. The virtual server will intercept SSL traffic, decrypt the traffic, and

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

forward it to a service that is bound to the virtual server. To secure time-sensitive traffic, such as media streaming, you can configure a DTLS virtual server. To enable SSL offloading, you must import a valid certificate and key and bind the pair to the virtual server.

Enable SSL

To process SSL traffic, you must enable SSL processing. You can configure SSL based entities, such as virtual servers and services, without enabling SSL processing. However, they do not work until SSL processing is enabled.

Enable SSL processing by using the CLI

At the command prompt, type:

```
enable ns feature ssl

show ns feature
```

Example:

```
enable ns feature SSL
 Done
show ns feature

        Feature                         Acronym             Status
        -------                         -------             ------
 1)     Web Logging                     WL                  OFF
 2)     Surge Protection                SP                  ON
 3)     Load Balancing                  LB                  ON
 .
 .
 .
 9)     SSL Offloading                  SSL                 ON
 .
 .
 .
 24)    NetScaler Push                  push                OFF
 Done
```

Enable SSL processing by using the GUI

Navigate to **System > Settings** and, in the **Modes and Features** group, click **Configure Basic Features**, and click **SSL Offloading**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure services

On the Citrix ADC appliance, a service represents a physical server or an application on a physical server. Once configured, services are in the disabled state until the appliance can reach the physical server on the network and monitor its status.

Add a service by using the CLI

At the command prompt, type the following commands to add a service and verify the configuration:

```
add service <name> (<IP> | <serverName>) <serviceType> <port>
show service <serviceName>
```

Example:

```
add service sslsvc 198.51.100.225 SSL 443

Done

sh ssl service sslsvc

            Advanced SSL configuration for Back-end SSL Service sslsvc:
            DH: DISABLED
            DH Private-Key Exponent Size Limit: DISABLED    Ephemeral
                RSA: DISABLED
            Session Reuse: ENABLED          Timeout: 300 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Server Auth: DISABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            OCSP Stapling: DISABLED
            SSLv2: DISABLED  SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1:
                ENABLED  TLSv1.2: ENABLED  TLSv1.3: DISABLED
            Send Close-Notify: YES
            Strict Sig-Digest Check: DISABLED
            Zero RTT Early Data: ???
            DHE Key Exchange With PSK: ???
            Tickets Per Authentication Context: ???

            ECC Curve: P_256, P_384, P_224, P_521

    1)      Cipher Name: DEFAULT_BACKEND
            Description: Default cipher list for Backend SSL session
     Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Modify or remove a service by using the CLI

To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service.

To remove a service, use the rm service command, which accepts only the <name> argument.

```
rm service <servicename>
```

Example:

```
rm service sslsvc
```

To modify a service, use the set service command, select any parameter, and change its setting.

```
set service <name> (<IP> | <serverName>) <serviceType> <port>
```

Example:

```
set service sslsvc 198.51.100.225 SSL 443
```

Configure a service by using the GUI

Navigate to **Traffic Management > Load Balancing > Services**, create a service, and specify the protocol as SSL.

SSL virtual server configuration

Secure sessions require establishing a connection between the client and an SSL-based virtual server on the Citrix ADC appliance. The SSL virtual server intercepts SSL traffic, decrypts it and processes it before sending it to services that are bound to the virtual server.

Note: The SSL virtual server is marked as down on the Citrix ADC appliance until a valid certificate / key pair and at least one service are bound to it. An SSL based virtual server is a load balancing virtual server of protocol type SSL or SSL_TCP. The load balancing feature must be enabled on the Citrix ADC appliance.

Add an SSL-based virtual server by using the CLI

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

```
add lb vserver <name> (serviceType) <IPAddress> <port>
show ssl vserver <name>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
add lb vserver sslvs SSL 192.0.2.240 443
Done

sh ssl vserver sslvs

            Advanced SSL configuration for VServer sslvs:
            DH: DISABLED
            DH Private-Key Exponent Size Limit: DISABLED    Ephemeral
               RSA: ENABLED          Refresh Count: 0
            Session Reuse: ENABLED          Timeout: 120 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Client Auth: DISABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            OCSP Stapling: DISABLED
            HSTS: DISABLED
            HSTS IncludeSubDomains: NO
            HSTS Max-Age: 0
            SSLv2: DISABLED  SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1:
                ENABLED  TLSv1.2: ENABLED  TLSv1.3: DISABLED
            Push Encryption Trigger: Always
            Send Close-Notify: YES
            Strict Sig-Digest Check: DISABLED
            Zero RTT Early Data: DISABLED
            DHE Key Exchange With PSK: NO
            Tickets Per Authentication Context: 1
            ECC Curve: P_256, P_384, P_224, P_521

     1)     Cipher Name: DEFAULT
            Description: Default cipher list with encryption strength
               >= 128bit
      Done
```

Modify or remove an SSL-based virtual server by using the CLI

To modify the load balancing properties of an SSL virtual server, use the `set lb vserver` command. The set command is similar to the `add lb vserver` command, except that you enter the name of an existing virtual server. To modify the **SSL** properties of an SSL-based virtual server, use the `set ssl vserver` command. For more information, see the "SSL virtual server parameters" section later in this page.

To remove an SSL virtual server, use the `rm lb vserver` command, which accepts only the <`name` > argument.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure an SSL-based virtual server by using the GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, create a virtual server, and specify the protocol as SSL.

Bind services to the SSL virtual server

The ADC appliance forwards decrypted SSL data to servers in the network. To forward data, services representing these physical servers must be bound to the virtual server that receives the SSL data.

Typically, the link between the ADC appliance and the physical server is secure. Therefore, data transfer between the appliance and the physical server does not have to be encrypted. However, you can provide end-to end-encryption by encrypting data transfer between the appliance and the server. For details, see Configure SSL offloading with end to end encryption.

Note: Enable the load balancing feature on the ADC appliance before you bind services to the SSL based virtual server.

Bind a service to a virtual server by using the CLI

At the command prompt, type the following commands to bind the service to the virtual server and verify the configuration:

```
bind lb vserver <name> <serviceName>
show lb vserver <name>
```

Example:

```
bind lb vserver sslvs sslsvc
     Done

sh lb vserver sslvs

            sslvs (192.0.2.240:443) - SSL       Type: ADDRESS
            State: DOWN[Certkey not bound]
            Last state change was at Wed May  2 11:43:04 2018
            Time since last state change: 0 days, 00:13:21.150
            Effective State: DOWN
            Client Idle Timeout: 180 sec
            Down state flush: ENABLED
            Disable Primary Vserver On Down : DISABLED
            Appflow logging: ENABLED
            No. of Bound Services :  1 (Total)       0 (Active)
            Configured Method: LEASTCONNECTION      BackupMethod:
               ROUNDROBIN
            Mode: IP
            Persistence: NONE
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
            Vserver IP and Port insertion: OFF
            Push: DISABLED  Push VServer:
            Push Multi Clients: NO
            Push Label Rule: none
            L2Conn: OFF
            Skip Persistency: None
            Listen Policy: NONE
            IcmpResponse: PASSIVE
            RHIstate: PASSIVE
            New Service Startup Request Rate: 0 PER_SECOND, Increment
               Interval: 0
            Mac mode Retain Vlan: DISABLED
            DBS_LB: DISABLED
            Process Local: DISABLE
            Traffic Domain: 0
            TROFS Persistence honored: ENABLED
            Retain Connections on Cluster: NO
    1) sslsvc (198.51.100.225: 443) - SSL State: DOWN       Weight: 1
     Done
```

Unbind a service from a virtual server by using the CLI

At the command prompt, type the following command:

```
unbind lb vserver <name> <serviceName>
```

Example:

```
unbind lb vserver sslvs sslsvc
     Done
```

Bind a service to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and click the **Load Balancing Virtual Server Service Bindings** tile under the **Services and Service Groups** section.
3. In the **Load Balancing Virtual Server Service Binding** page, click **Add Bindings** tab, click **Click to select** under **Select Service**, and select the check box next to the service to be bound.
4. Click **Select** and click **Bind**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure a server name indication (SNI) virtual server for secure hosting of multiple sites

Virtual hosting is used by web servers to host more than one domain name with the same IP address. The appliance supports hosting of multiple secure domains by offloading SSL processing from the web servers using transparent SSL services or virtual server-based SSL offloading. However, when multiple websites are hosted on the same virtual server, the SSL handshake is completed before the expected host name is sent to the virtual server. As a result, the appliance cannot determine which certificate to present to the client after a connection is established. This problem is resolved by enabling SNI on the virtual server. SNI is a Transport Layer Security (TLS) extension used by the client to provide the host name during handshake initiation. The ADC appliance compares this host name to the common name and, if it does not match, compares it to the subject alternative name (SAN). If the name matches, the appliance presents the corresponding certificate to the client.

A wildcard SSL certificate helps enable SSL encryption on multiple subdomains if the same organization controls these domains and the second-level domain name is the same. For example, a wildcard certificate issued to a sports network using the common name "*.sports.net"can be used to secure domains, such as "login.sports.net"and "help.sports.net". It cannot secure the "login.ftp.sports.net" domain.

Note:
On an ADC appliance, only domain name, URL, and email ID DNS entries in the **SAN** field are compared.

You can bind multiple server certificates to a single SSL virtual server or transparent service using the -SNICert option. The virtual server or service issues these certificates if SNI is enabled on the virtual server or service. You can enable SNI at any time.

Bind multiple server certificates to a single SSL virtual server by using the CLI

At the command prompt, type the following commands to configure SNI and verify the configuration:

```
set ssl vserver <vServerName>@ [-SNIEnable ( ENABLED | DISABLED )]

bind ssl vserver <vServerName>@ -certkeyName <string> -SNICert

show ssl vserver <vServerName>
```

To bind multiple server certificates to a transparent service by using the CLI, replace `vserver` with service and `vservername` with service name in the preceding commands.

Note: Create the SSL service with the `-clearTextPort 80` option.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Bind multiple server certificates to a single SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open an SSL virtual server and, in **Certificates**, select **Server Certificate**.
3. Add a certificate or select a certificate from the list, and click **Server Certificate for SNI**.
4. In **Advanced Settings**, select **SSL Parameters**.
5. Click **SNI Enable**.

Support for SNI on the back-end service

> **Note**: SNI is not supported on a DTLS back-end service.

The Citrix ADC appliance supports Server Name Indication (SNI) at the back end. That is, the common name is sent as the server name in the client hello to the back-end server for successful completion of the handshake. This support helps meet federal system integrator customer security requirements. Also, SNI provides the advantage of using only one port instead of opening hundreds of different IP addresses and ports on a firewall.

Federal system integrator customer security requirements include support for Active Directory Federation Services (ADFS) 3.0 in 2012R2 and WAP servers. To meet this requirement, support for SNI at the back end on a Citrix ADC appliance is required.

> **Note:**
>
> For SNI to work, the server name in the client hello must match the host name configured on the back-end service that is bound to an SSL virtual server. For example, if the host name of the back-end server is www.mail.example.com, the SNI-enabled back-end service must be configured with the server name as https://www.mail.example.com. And this host name must match the server name in the client hello.

Support for dynamic SNI on the back-end service

The Citrix ADC appliance supports dynamic SNI on the back-end TLS connections. That is, the appliance learns the SNI in the client connection and uses it in the server-side connection. You no longer need to specify a common name in the SSL service, service group, or profile. The common name received in the SNI extension of the Client Hello message is forwarded to the back-end SSL connection.

Earlier, you had to configure static SNI on SSL services, service groups, and SSL profiles. As a result, only the configured static SNI extension was sent to the server. If a client needed to access multiple domains at the same time, the ADC appliance was not able to send the SNI received from the client to the back-end service. Instead, it sent the static common name that was configured. Now, if the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

back-end server is configured for multiple domains, the server can respond with the correct certificate based on the SNI received in the Client Hello message from the appliance.

Point to Note:

- SNI must be enabled on the front end and the correct SNI certificate bound to the SSL virtual server. If you don't enable SNI on the front end, the SNI information is not passed to the back end.
- When server authentication is enabled, the server certificate is verified by the CA certificate and the common name/SAN entries in the server certificate are matched with the SNI. Therefore, the CA certificate must be bound to the service.
- Reuse of back-end connection and SSL session is based on SNI when dynamic SNI is enabled.

SSL monitors do not send SNI when dynamic SNI is enabled. For SNI based probing, attach a back-end profile on which static SNI is configured to the SSL monitors. The monitor must be configured with the same custom header as SNI.

Configure SNI on the back-end service by using the CLI

At the command prompt, type:

```
add service <name>  <IP>  <serviceType>  <port>

add lb vserver <name>  <IPAddress> <serviceType>  <port>

bind lb vserver <name> <serviceName>

set ssl service <serviceName> -SNIEnable ENABLED -commonName <string>

set ssl profile <name> -SNIEnable ENABLED
```

Example:

```
    add service service_ssl 198.51.100.100 SSL 443

    add lb vserver ssl-vs 203.0.113.200 SSL 443

    bind lb vserver ssl-vs service_ssl

    set ssl service service_ssl -SNIEnable ENABLED – commonName www.
       example.com

    set ssl profile sslprof -SNIEnable ENABLED
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure SNI on the back-end service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Select an SSL service, and in **Advanced Settings**, click **SSL Parameters**.
3. Click **SNI Enable**.

Configure SNI on the SSL profile by using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. Click **Add**.
3. In **Basic Settings**, select **SNI Enable**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

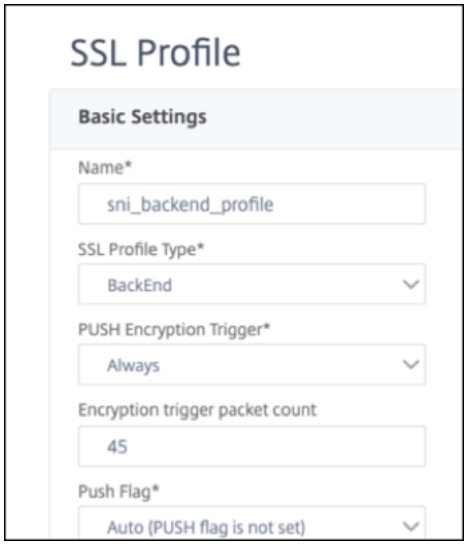
4. Click **OK**.

Bind a secure monitor to an SNI-enabled back-end service

You can bind secure monitors of type HTTP, HTTP-ECV, TCP, or TCP-ECV to the back-end services and service groups that support SNI. However, the monitor probes do not send the SNI extension if dynamic SNI is enabled. To send SNI probes, enable static SNI in the back-end SSL profile and bind the profile to the monitor. Set the custom header in the monitor to the server name that is sent as the SNI extension in the client hello of the monitor probe.

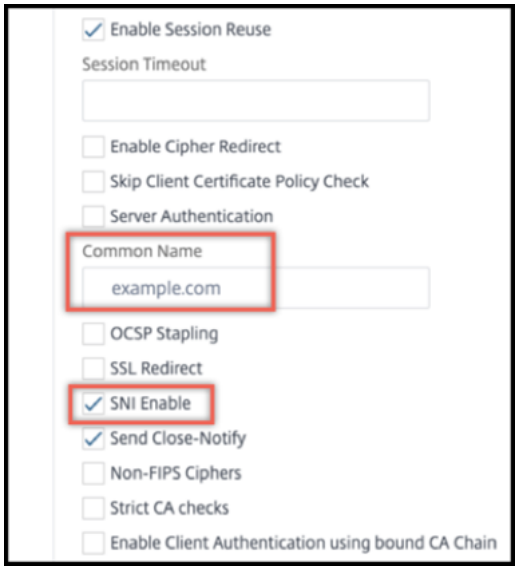
Configure and bind a secure monitor to an SNI-enabled back-end service by using the CLI At the command prompt, type:

```
add lb monitor <monitorName> <type> -secure YES
add ssl profile <name> -sslProfileType BackEnd
set lb monitor <monitorName> <type> -customHeaders <string> -sslprofile
    <backend ssl profile>
set ssl profile <name> -sniEnable ENABLED -commonName <string>
bind service <name> -monitorName <string>
```



Example:

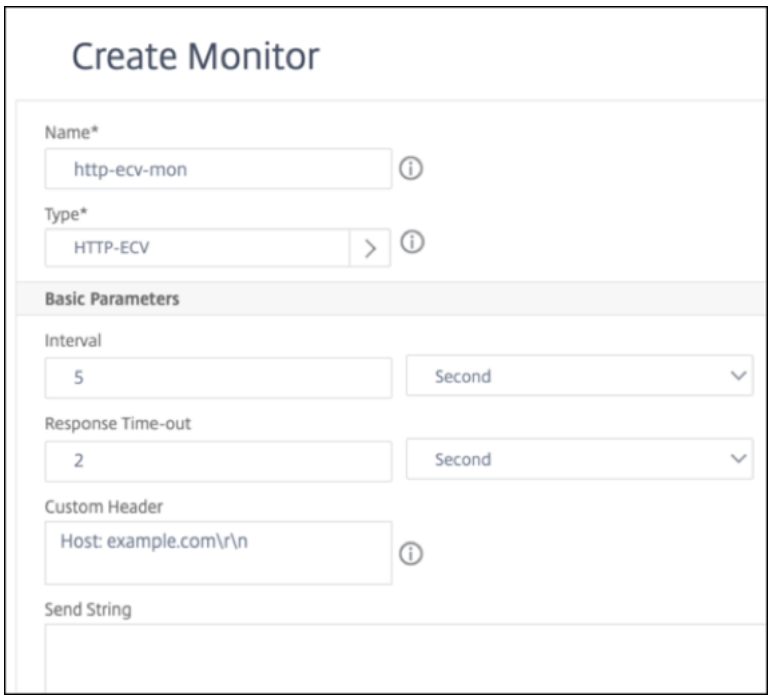
```
add ssl profile sni_backend_profile -sslProfileType BackEnd
set ssl profile sni_backend_profile -sniEnable ENABLED -commonName
   example.com
add lb monitor http-ecv-mon HTTP-ECV -secure YES
set monitor http-ecv-mon HTTP-ECV -customHeaders "Host: example.com\r\n
   " -sslprofile sni_backend_profile
bind service ssl_service – monitorName http-ecv-mon
```



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure and bind a secure monitor to an SNI enabled back-end service by using the GUI

1. Navigate to **System > Profiles > SSL Profiles**.
2. Click **Add**.
3. Specify a name for the profile and in **SSL Profile Type**, select **Backend**.



4. Specify the common name (same as host header) and select **SNI Enable**.

5. Click **OK**.
6. Navigate to **Traffic Management > Load Balancing > Monitor**.
7. Click **Add**.
8. Specify a name for the monitor. In **Type**, select HTTP, HTTP-ECV, TCP, or TCP-ECV.
9. Specify a **Custom Header**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

10. Select **Secure**.
11. In **SSL Profile**, select the back-end SSL profile created in the preceding steps.
12. Click **Create**.
13. Navigate to **Traffic Management > Load Balancing > Services**.
14. Select an SSL service and click **Edit**.
15. In **Monitors**, click **Add Binding**, select the monitor created in the preceding steps, and click **Bind**.

Configure and bind a secure monitor to an SNI-enabled back-end service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitor**.
2. Add a monitor of type **HTTP-ECV** or **TCP-ECV**, and specify a **Custom Header**.
3. Select **Create**.
4. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
5. Select an SSL service and click **Edit**.
6. In **Monitors**, click **Add Binding**, select the monitor created in step 3, and click **Bind**.

Add or update a certificate-key pair

> **Notes:**
>
> If you don't have an existing certificate and key, see Create a certificate.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> To create an ECDSA certificate-key pair, click Create an ECDSA certificate-key pair.
>
> From build 41.x, certificate names of up to 63 characters are supported.
>
> From release 13.0 build 79.x, password protected certificate-key pairs are always added successfully. Earlier, if the strong password option was enabled on a Citrix ADC appliance, sometimes the password protected certificate-key pairs were not added. However, the certificate-key configuration is lost if you downgrade to an earlier build. Also, in the NITRO API response for certificate-key pairs, the `passplain` variable is sent instead of the `passcrypt` variable.

For any SSL transaction, the server needs a valid certificate and the corresponding private and public key pair. The SSL data is encrypted with the server's public key, which is available through the server's certificate. Decryption requires the corresponding private key. The password of the private key used while adding an SSL certificate-key pair is saved using a unique encryption key for each Citrix ADC appliance.

The ADC appliance offloads SSL transactions from the server. Therefore, the server's certificate and private key must be present on the appliance, and the certificate must be paired with its corresponding private key. This certificate-key pair must be bound to the virtual server that processes the SSL transactions.

Note: The default certificate on a Citrix ADC appliance is 2048 bits. In earlier builds, the default certificate was 512 bits or 1024 bits. After upgrading to release 11.0, you must delete all your old certificate-key pairs starting with `"ns-"`, and then restart the appliance to automatically generate a 2048-bit default certificate.

Both the certificate and the key must be in local storage on the Citrix ADC appliance before they can be added to the appliance. If your certificate or key file is not on the appliance, upload it to the appliance before you create the pair.

Important: Certificates and keys are stored in the /nsconfig/ssl directory by default. If your certificates or keys are stored in any other location, you must provide the absolute path to the files on the Citrix ADC appliance. The Citrix ADC FIPS appliances do not support external keys (non-FIPS keys). On a FIPS appliance, you cannot load keys from a local storage device such as a hard disk or flash memory. The FIPS keys must be present in the Hardware Security Module (HSM) of the appliance.

Only RSA keys are supported on Citrix ADC appliances.

Set the notification period and enable the expiry monitor to issue a prompt before the certificate expires.

The Citrix ADC appliance supports the following input formats of the certificate and the private-key files:

- PEM - Privacy Enhanced Mail
- DER - Distinguished Encoding Rule

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- PFX - Personal Information Exchange

The software automatically detects the format. Therefore, you are no longer required to specify the format in the inform parameter. If you do specify the format (correct or incorrect), the software ignores it. The format of the certificate and the key file must be the same.

Note: A certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

An MPX appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A VPX virtual appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

> **Note**
>
> A Citrix ADC SDX appliance supports certificates of 512 or more bits. Each Citrix ADC VPX instance hosted on the appliance supports the preceding certificate sizes for a VPX virtual appliance. However, if an SSL chip is assigned to an instance, that instance supports the certificate sizes supported by an MPX appliance.

Add a certificate-key pair by using the CLI

At the command prompt, type the following commands to add a certificate-key pair and verify the configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add ssl certKey <certkeyName> -cert <string>[(-key <string> [-password
    ]) | -fipsKey <string>] [-inform ( DER | PEM )] [<passplain>] [-
    expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <
    positive_integer>]]

show ssl certKey [<certkeyName>]
```

Example:

```
add ssl certKey sslckey -cert server_cert.pem -key server_key.pem -
    password ssl -expiryMonitor ENABLED -notificationPeriod 30
 Done
Note: For FIPS appliances, replace -key with -fipskey

show ssl certKey sslckey
        Name: sslckey           Status: Valid,   Days to expiration
            :8418
        Version: 3
        Serial Number: 01
        Signature Algorithm: md5WithRSAEncryption
        Issuer:  C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.root.com
        Validity
                Not Before: Jul 15 02:25:01 2005 GMT
                Not After : Nov 30 02:25:01 2032 GMT
        Subject:  C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.server.com
        Public Key Algorithm: rsaEncryption
        Public Key size: 2048
 Done
```

Update or remove a certificate-key pair by using the CLI

To modify the expiry monitor or notification period in a certificate-key pair, use the `set ssl certkey` command. To replace the certificate or key in a certificate-key pair, use the `update ssl certkey` command. The `update ssl certkey` command has an extra parameter for overriding the domain check. For both commands, enter the name of an existing certificate-key pair. To remove an SSL certificate-key pair, use the `rm ssl certkey` command, which accepts only the `<certkeyName>` argument.

Example:

```
set ssl certKey <certkeyName> [-expiryMonitor ( ENABLED | DISABLED )
       [-notificationPeriod <positive_integer>]]

update ssl certKey <certkeyName> [-cert <string> [-password]] [-key
       <string> | -fipsKey <string>] [-inform <inform>] [-noDomainCheck
          ]
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Add or update a certificate-key pair by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates > Server**.
2. Enter the values for the following parameters and click **Install**.
    - Certificate-Key Pair Name - Name for the certificate and private-key pair.
    - Certificate File Name - Signed certificate received from the certificate authority.
    - Key File Name - Name of and, optionally, path to the private-key file that is used to form the certificate-key pair.

Bind the certificate-key pair to the SSL virtual server

Important: Link any intermediate certificates to this certificate before binding the certificate to an SSL virtual server. For information about linking certificates, see Create a chain of certificates.

The certificate being used for processing SSL transactions must be bound to the virtual server that receives the SSL data. If you have multiple virtual servers receiving SSL data, a valid certificate-key pair must be bound to each of them.

Use a valid, existing SSL certificate that you have uploaded to the Citrix ADC appliance. As an alternative for testing purposes, create your own SSL certificate on the appliance. Intermediate certificates created by using a FIPS key on the appliance cannot be bound to an SSL virtual server.

During the SSL handshake, in the certificate request message during client authentication, the server lists the distinguished names (DN) of all the certificate authorities (CA) bound to the server. The server accepts a client certificate only from this list. If you do not want the DN name of a specific CA certificate to be sent to the SSL client, set the `skipCA` flag. This setting indicates that the particular CA certificate's distinguished name must not be sent to the SSL client.

For details on how to create your own certificate, see Managing Certificates.

Note: Citrix recommends that you use only valid SSL certificates issued by a trusted certificate authority.

Bind an SSL certificate-key pair to a virtual server by using the CLI

At the command prompt, type the following commands to bind an SSL certificate-key pair to a virtual server and verify the configuration:

```
1 - bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName
    > -CA -skipCAName
2 - show ssl vserver <vServerName>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
bind ssl vs vs1 -certkeyName cert2 -CA -skipCAName
 Done
sh ssl vs vs1

 Advanced SSL configuration for VServer vs1:

 DH: DISABLED

 Ephemeral RSA: ENABLED Refresh Count: 0

 Session Reuse: ENABLED Timeout: 120 seconds

 Cipher Redirect: DISABLED

 SSLv2 Redirect: DISABLED

 ClearText Port: 0

 Client Auth: DISABLED

 SSL Redirect: DISABLED

 Non FIPS Ciphers: DISABLED

 SNI: DISABLED

 OCSP Stapling: DISABLED

 HSTS: DISABLED

 IncludeSubDomains: NO

 HSTS Max-Age: 0

 SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1: DISABLED
    TLSv1.2: DISABLED

 Push Encryption Trigger: Always

 Send Close-Notify: YES

 Strict Sig-Digest Check: DISABLED

ECC Curve: P_256, P_384, P_224, P_521

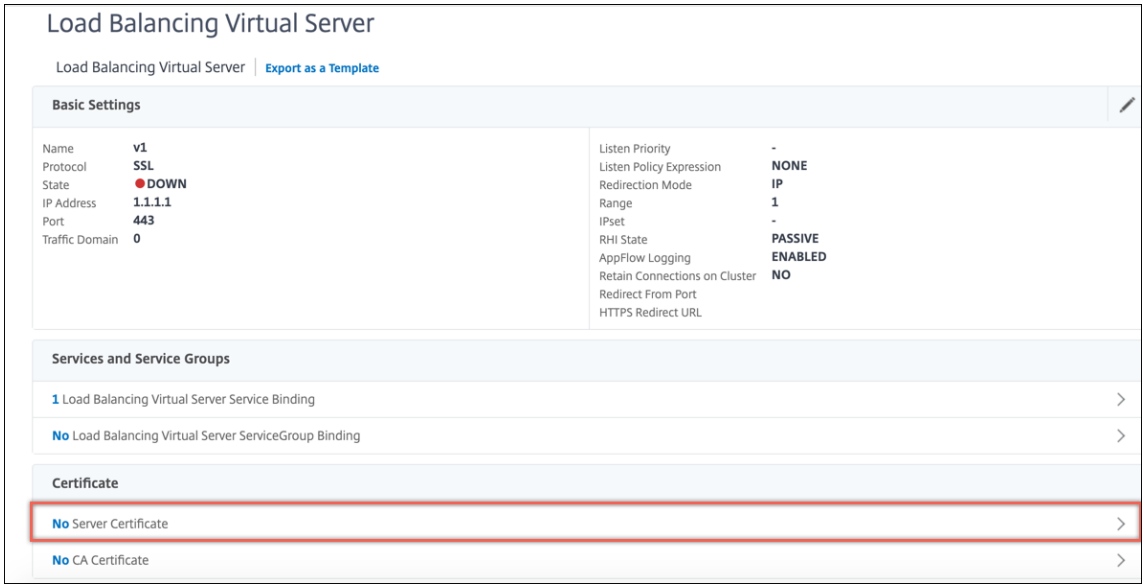
 1) CertKey Name: cert1 CA Certificate OCSPCheck: Optional CA_Name Sent
 2) CertKey Name: cert2 CA Certificate OCSPCheck: Optional CA_Name
    Skipped
 1) Cipher Name: DEFAULT

Description: Default cipher list with encryption strength >= 128bit
Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

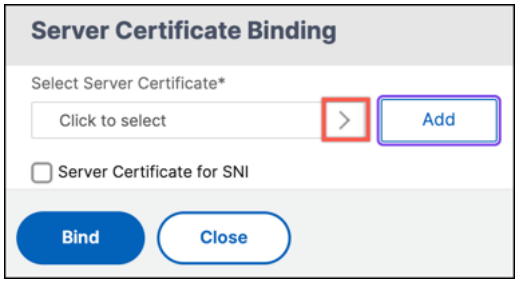
Unbind an SSL certificate-key pair from a virtual server by using the CLI

If you try to unbind a certificate-key pair from a virtual server by using the `unbind ssl certKey <certkeyName>` command, an error message appears. The error appears because the syntax of the command has changed. At the command prompt, type the following command:



```
unbind ssl vserver <vServerName> -certkeyName <string>
```

Example:



```
unbind ssl vserver vssl -certkeyName sslckey
```

Bind an SSL certificate-key pair to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and open an SSL virtual server. Click inside the **Certificate** section.

2. Click the arrow to select the certificate-key pair.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. Select the certificate-key pair from the list.
4. Bind the certificate-key pair to the virtual server. To add a server certificate as an SNI certificate, select **Server Certificate for SNI**.

SSL virtual server parameters

Set the advanced SSL configuration for an SSL virtual server. You can also set many of these parameters in an SSL profile. For information about the parameters that can be set in an SSL profile, see SSL profile parameters.

Set SSL virtual server parameters by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName>@ [-clearTextPort <port>] [-dh ( ENABLED |
    DISABLED ) -dhFile <string>] [-dhCount <positive_integer>][-
    dhKeyExpSizeLimit ( ENABLED | DISABLED )] [-eRSA ( ENABLED |
    DISABLED) [-eRSACount <positive_integer>]] [-sessReuse ( ENABLED |
    DISABLED )[-sessTimeout <positive_integer>]] [-cipherRedirect (
    ENABLED | DISABLED ) [-cipherURL <URL>]] [-sslv2Redirect ( ENABLED |
     DISABLED )[-sslv2URL <URL>]] [-clientAuth ( ENABLED | DISABLED ) [-
    clientCert ( Mandatory | Optional )]] [-sslRedirect ( ENABLED |
    DISABLED )][-redirectPortRewrite ( ENABLED | DISABLED )] [-ssl2 (
    ENABLED | DISABLED )] [-ssl3 ( ENABLED | DISABLED )] [-tls1 (
    ENABLED | DISABLED )] [-tls11 ( ENABLED | DISABLED )] [-tls12 (
    ENABLED | DISABLED )][-tls13 ( ENABLED | DISABLED )] [-SNIEnable (
    ENABLED | DISABLED )][-ocspStapling ( ENABLED | DISABLED )] [-
    pushEncTrigger <pushEncTrigger>] [-sendCloseNotify ( YES | NO )] [-
    dtlsProfileName <string>] [-sslProfile <string>] [-HSTS ( ENABLED |
    DISABLED )][-maxage <positive_integer>] [-IncludeSubdomains ( YES |
    NO )][-strictSigDigestCheck ( ENABLED | DISABLED )] [-
    zeroRttEarlyData (ENABLED | DISABLED )] [-
    tls13SessionTicketsPerAuthContext <positive_integer>] [-
    dheKeyExchangeWithPsk ( YES | NO )]
```

Diffie-Hellman (DH) parameters

To use ciphers on the appliance that require a DH key exchange to set up the SSL transaction, enable DH key exchange on the appliance. Configure other settings based on your network.

To list the ciphers for which DH parameters must be set by using the CLI, type: sh cipher DH.

To list the ciphers for which DH parameters must be set by using the configuration utility, navigate to **Traffic Management > SSL > Cipher Groups**, and double-click **DH**.

For details on how to enable DH key exchange, see Generate a Diffie-Hellman (DH) key.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure DH parameters by using the CLI At the command prompt, type the following commands to configure DH parameters and verify the configuration:

```
- `set ssl vserver <vserverName> -dh <Option> -dhCount <
   RefreshCountValue> -filepath <string>
- show ssl vserver <vServerName>`
```

Example:

```
set ssl vserver vs-server -dh ENABLED  -dhFile /nsconfig/ssl/ns-server.
   cert -dhCount 1000
Done

show ssl vserver vs-server

            Advanced SSL configuration for VServer vs-server:
            DH: ENABLED
            Ephemeral RSA: ENABLED          Refresh Count: 1000
            Session Reuse: ENABLED          Timeout: 120 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Client Auth: DISABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            OCSP Stapling: DISABLED
            HSTS: DISABLED
            HSTS IncludeSubDomains: NO
            HSTS Max-Age: 0
            SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED TLSv1.2:
               ENABLED  TLSv1.2: ENABLED

    1)      Cipher Name: DEFAULT
            Description: Predefined Cipher Alias
Done
```

Configure DH parameters by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable DH Param**, and specify a refresh count and file path.

Ephemeral RSA

Ephemeral RSA allows export clients to communicate with the secure server even if the server certificate does not support export clients (1024-bit certificate). If you want to prevent export clients from accessing the secure web object or resource, you need to disable ephemeral RSA key exchange.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

By default, this feature is enabled on the Citrix ADC appliance, with the refresh count set to zero (infinite use).

Note:

The ephemeral RSA key is automatically generated when you bind an export cipher to an SSL or TCP-based SSL virtual server or service. When you remove the export cipher, the eRSA key is not deleted. It is reused later when another export cipher is bound to an SSL or TCP-based SSL virtual server or service. The eRSA key is deleted when the system restarts.

Configure ephemeral RSA by using the CLI At the command prompt, type the following commands to configure ephemeral RSA and verify the configuration:

```
set ssl vserver <vServerName> -eRSA (enabled | disabled) -eRSACount <
   positive_integer>
show ssl vserver <vServerName>
```

Example:

```
set ssl vserver vs-server -eRSA ENABLED -eRSACount 1000
 Done

show ssl vserver vs-server

        Advanced SSL configuration for VServer vs-server:
        DH: DISABLED
        Ephemeral RSA: ENABLED          Refresh Count: 1000
        Session Reuse: ENABLED          Timeout: 120 seconds
        Cipher Redirect: DISABLED
        SSLv2 Redirect: DISABLED
        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        OCSP Stapling: DISABLED
        HSTS: DISABLED
        HSTS IncludeSubDomains: NO
        HSTS Max-Age: 0
        SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED TLSv1.2:
           ENABLED  TLSv1.2: ENABLED

1)      Cipher Name: DEFAULT
        Description: Predefined Cipher Alias
 Done
```

Configure ephemeral RSA by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. In the **SSL Parameters** section, select **Enable Ephemeral RSA**, and specify a refresh count.

Session reuse

For SSL transactions, establishing the initial SSL handshake requires CPU-intensive public key encryption operations. Most handshake operations are associated with the exchange of the SSL session key (client key exchange message). When a client session is idle for some time and is then resumed, the SSL handshake is typically conducted all over again. With session reuse enabled, session key exchange is avoided for session resumption requests received from the client.

Session reuse is enabled on the Citrix ADC appliance by default. Enabling this feature reduces server load, improves response time, and increases the number of SSL transactions per second (TPS) that the server can support.

Configure session reuse by using the CLI At the command prompt, type the following commands to configure session reuse and verify the configuration:

```
set ssl vserver <vServerName> -sessReuse ( ENABLED | DISABLED ) -
    sessTimeout <positive_integer>
show ssl vserver <vServerName>
```

Example:

```
set ssl vserver vs-ssl -sessreuse enabled -sesstimeout 600
 Done

show ssl vserver vs-ssl

        Advanced SSL configuration for VServer vs-ssl:
        DH: DISABLED
        Ephemeral RSA: ENABLED          Refresh Count: 1000
        Session Reuse: ENABLED          Timeout: 600 seconds
        Cipher Redirect: DISABLED
        SSLv2 Redirect: DISABLED
        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        OCSP Stapling: DISABLED
        HSTS: DISABLED
        HSTS IncludeSubDomains: NO
        HSTS Max-Age: 0
        SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED TLSv1.2:
            ENABLED  TLSv1.2: ENABLED

1)      CertKey Name: Auth-Cert-1       Server Certificate

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
1)      Cipher Name: DEFAULT
        Description: Predefined Cipher Alias
 Done
```

Configure session reuse by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable Session Reuse**, and specify a time for which to keep the session active.

SSL protocol settings

The Citrix ADC appliance supports the SSLv3, TLSv1, TLSv1.1, and TLSv1.2 protocols. Each of these protocols can be set on the appliance as required by your deployment and the type of clients that connect to the appliance.

TLS protocol versions 1.0, 1.1, and 1.2 are more secure than older versions of the TLS/SSL protocol. However, to support legacy systems, many TLS implementations maintain backward compatibility with the SSLv3 protocol. In an SSL handshake, the highest protocol version common to the client and the SSL virtual server configured on the Citrix ADC appliance is used.

In the first handshake attempt, a TLS client offers the highest protocol version that it supports. If the handshake fails, the client offers a lower protocol version. For example, if a handshake with TLS version 1.1 is not successful, the client attempts to renegotiate by offering the TLSv1.0 protocol. If that attempt is unsuccessful, the client reattempts with the SSLv3 protocol. A "man in the middle" (MITM) attacker can break the initial handshake and trigger renegotiation with the SSLv3 protocol, and then exploit a vulnerability in SSLv3. To mitigate such attacks, you can disable SSLv3 or not allow renegotiation using a downgraded protocol. However, this approach might not be practical if your deployment includes legacy systems. An alternative is to recognize a signaling cipher suite value (TLS_FALLBACK_SCSV) in the client request.

A TLS_FALLBACK_SCSV value in a client hello message indicates to the virtual server that the client has previously attempted to connect with a higher protocol version and that the current request is a fallback. If the virtual server detects this value, and it supports a version higher than the one indicated by the client, it rejects the connection with a fatal alert. The handshake succeeds if one of the following conditions is met:

- TLS_FALLBACK_SCSV value is not included in the client hello message.
- The protocol version in the client hello is the highest protocol version supported by the virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure SSL protocol support by using the CLI At the command prompt, type the following commands to configure SSL protocol support and verify the configuration:

```
set ssl vserver <vServerName> -ssl2 ( ENABLED | DISABLED ) -ssl3 (
    ENABLED | DISABLED ) -tls1 ( ENABLED | DISABLED ) -tls11 ( ENABLED |
     DISABLED ) -tls12 ( ENABLED | DISABLED )

show ssl vserver <vServerName>
```

Example:

```
set ssl vserver vs-ssl -tls11 ENABLED -tls12 ENABLED
Done

sh ssl vs vs-ssl

        Advanced SSL configuration for VServer vs-ssl:
            DH: DISABLED
            Ephemeral RSA: ENABLED                              Refresh
               Count: 0
            Session Reuse: ENABLED                                Timeout
               : 120 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Client Auth: DISABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            SSLv2: DISABLED        SSLv3: ENABLED    TLSv1.0: ENABLED
               TLSv1.1: ENABLED  TLSv1.2: ENABLED
            Push Encryption Trigger: Always
            Send Close-Notify: YES
            1 bound certificate:

    1)      CertKey Name: mycert  Server Certificate
            1 configured cipher:

    1)      Cipher Name: DEFAULT
            Description: Predefined Cipher Alias

Done
```

Configure SSL protocol support by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select a protocol to enable.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Close-notify

A close-notify is a secure message that indicates the end of SSL data transmission. A close-notify setting is required at the global level. This setting applies to all virtual servers, services, and service groups. For information about the global setting, see the "Global SSL parameters"section later in this page.

In addition to the global setting, you can set the close-notify parameter at the virtual server, service, or service group level. You therefore have the flexibility of setting the parameter for one entity and unsetting it for another entity. However, make sure that you set this parameter at the global level. Otherwise, the setting at the entity level does not apply.

Configure close-notify at the entity level by using the CLI At the command prompt, type any of the following commands to configure the close-notify feature and verify the configuration:

1. To configure at the virtual server level, type:

```
set ssl vserver <vServerName> -sendCloseNotify ( YES | NO )
show ssl vserver <vServerName>
```

1. To configure at the service level, type:

```
set ssl service <serviceName> -sendCloseNotify ( YES | NO )
show ssl service <serviceName>
```

1. To configure at the service group level, type:

```
set ssl serviceGroup <serviceGroupName> -sendCloseNotify ( YES | NO )
show ssl serviceGroup <serviceGroupName>
```

Example:

```
set ssl vserver sslvsvr -sendCloseNotify YES

Done
```

Configure the close-notify feature at the entity level by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Send Close-Notify**.

Global SSL parameters

Advanced customization of your SSL configuration addresses specific issues. You can use the `set ssl parameter` command or the configuration utility to specify the following:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Quantum size to be used for SSL transactions.
- CRL memory size.
- OCSP cache size.
- Deny SSL renegotiation.
- Set the PUSH flag for decrypted, encrypted, or all records.
- Drop requests if the client initiates the handshake for one domain and sends an HTTP request for another domain.
- Set the time after which encryption is triggered.
  Note: The time that you specify applies only if you use the `set ssl vserver` command or the configuration utility to set timer-based encryption.
- NDCPP compliance certificate check –Applies when the appliance acts a client (back-end connection). During certificate verification, ignore the common name if SAN is present in the SSL certificate.
- Enable a heterogeneous cluster of Cavium chip based appliances, such as MPX 14000, and Intel Coleto chip based appliances, such as MPX 15000 appliances with a different number of packet engines. (Support added in release 13.0 build 47.x).
- Enable secure renegotiation at the back end (Support added from release 1.0 build 58.x).
- Adaptive SSL traffic control (Support added in release 13.0 build 58.x).

Configure global SSL parameters by using the CLI

At the command prompt, type the following commands to configure advanced SSL settings and verify the configuration:

```
set ssl parameter [-quantumSize <quantumSize>] [-crlMemorySizeMB <
    positive_integer>] [-strictCAChecks (YES | NO)] [-sslTriggerTimeout
    <positive_integer>] [-sendCloseNotify (YES | NO)] [-
    encryptTriggerPktCount <positive_integer>] [-denySSLReneg <
    denySSLReneg>] [-insertionEncoding (Unicode|UTF-8)] [-ocspCacheSize
    <positive_integer>][- pushFlag <positive_integer>] [-
    dropReqWithNoHostHeader (YES | NO)] [-pushEncTriggerTimeout <
    positive_integer>] [-ndcppComplianceCertCheck ( YES | NO)] [-
    heterogeneousSSLHW (ENABLED | DISABLED )]
show ssl parameter
```

Example:

```
set ssl parameter -quantumSize 8 -crlMemorySizeMB 256 -strictCAChecks
    no -ssltriggerTimeout 100 -sendClosenotify no -
    encryptTriggerPktCount 45 -denySSLReneg NONSECURE -insertionEncoding

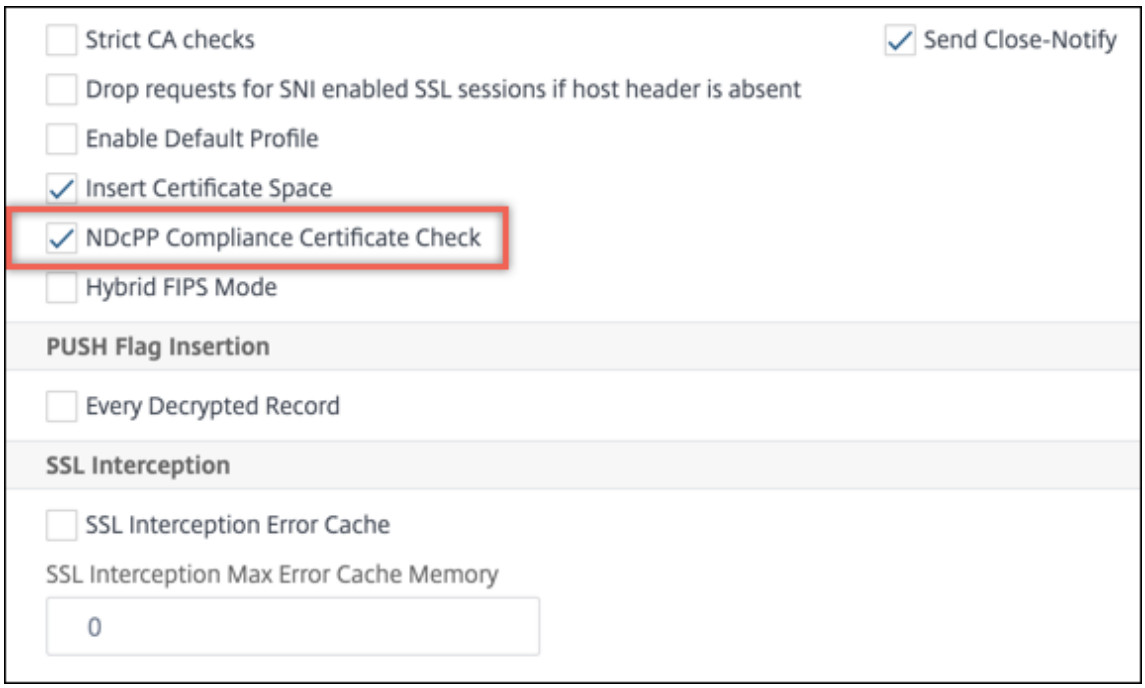
Advanced SSL Parameters
-----------------------
    SSL quantum size                                        : 8 KB
    Max CRL memory size                                     : 256 MB
    Strict CA checks                                        : NO
    Encryption trigger timeout                              : 100 ms
    Send Close-Notify                                       : NO
    Encryption trigger packet count                         : 45
    Deny SSL Renegotiation                                  : NONSECURE
    Subject/Issuer Name Insertion Format                    : Unicode
    OCSP cache size                                         : 10 MB
    Push flag                                               : 0x3 (On
       every decrypted and encrypted record)
    Strict Host Header check for SNI enabled SSL sessions : YES
    PUSH encryption trigger timeout                         : 100 ms
    Crypto Device Disable Limit                             : 0
    Global undef action for control policies                : CLIENTAUTH
    Global undef action for data policies                   : NOOP
    Default profile                                         : DISABLED
    SSL Insert Space in Certificate Header                  : YES
    Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors      : NO
    Disable TLS 1.1/1.2 for dynamic and VPN services        : NO
    Software Crypto acceleration CPU Threshold              : 0
    Hybrid FIPS Mode                                        : DISABLED
    Signature and Hash Algorithms supported by TLS1.2       : ALL
    SSL Interception Error Learning and Caching             : DISABLED
    SSL Interception Maximum Error Cache Memory             : 0 Bytes
    NDCPP Compliance Certificate Check                      : YES
    Heterogeneous SSL HW (Cavium and Intel Based)           : ENABLED
 Done
```



Configure NDcPP compliance certificate check by using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **Settings** group, select **Change advanced SSL settings**.

2. Select **NDCPP Compliance Certificate Check**. Click **OK**.

Support for secure renegotiation at the back end of a Citrix ADC appliance

Note: This feature is supported in release 13.0 build 58.x and later. In earlier releases and builds, only non-secure renegotiation was supported on the back end.

The feature is supported on the following platforms:
• VPX
• MPX platforms containing N2 or N3 chips
• Intel Coleto SSL chip based platforms

The feature is not yet supported on the FIPS platform.

Secure renegotiation is denied by default on the back end of an ADC appliance. That is, the `denySSLReneg` parameter is set to ALL (default).

To allow secure renegotiation on the back end, select from one of the following settings for the `denySSLReneg` parameter:

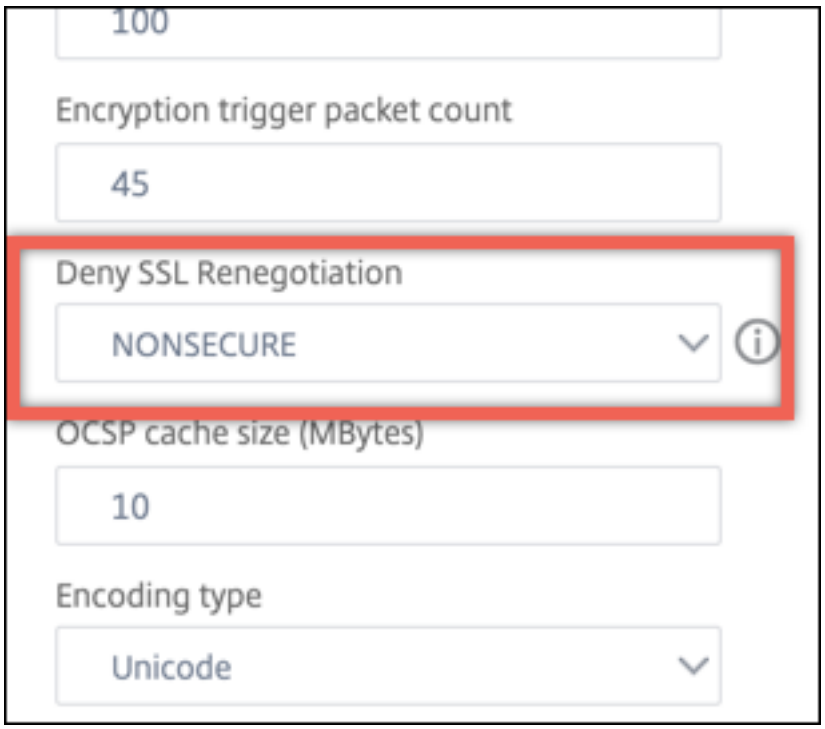
- NO
- FRONTEND_CLIENT
- FRONTEND_CLIENTSERVER
- NONSECURE

Enable secure renegotiation by using the CLI At the command prompt, type:

```
set ssl parameter -denySSLReneg <denySSLReneg>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:



```
set ssl parameter -denySSLReneg NONSECURE
 Done

sh ssl parameter
Advanced SSL Parameters

    Disable TLS 1.1/1.2 for dynamic and VPN services    : NO
    Software Crypto acceleration CPU Threshold          : 0
    Hybrid FIPS Mode                                    : DISABLED
    Signature and Hash Algorithms supported by TLS1.2   : ALL
    SSL Interception Error Learning and Caching         : DISABLED
    SSL Interception Maximum Error Cache Memory         : 0 Bytes
    NDCPP Compliance Certificate Check                  : NO
    Heterogeneous SSL HW (Cavium and Intel Based)       : DISABLED
    Crypto Operation Queue Limit                        : 150%
 Done
```

Enable secure renegotiation by using the GUI

1. Navigate to **Traffic Management > SSL > Change advanced SSL settings**.
2. Set **Deny SSL Renegotiation** to any value other than ALL.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Adaptive SSL traffic control

Note: This feature is supported in release 13.0 build 58.x and later.

When high traffic is received on the appliance and the crypto acceleration capacity is full, the appliance starts queuing connections to process later. Currently, the size of this queue is fixed at 64 K and the appliance starts dropping connections if this value is exceeded.

From release 13.0 build 58.x, the user can configure a value that is a percentage of the actual capacity. With this enhancement, the appliance drops new connections if the number of elements in the queue is greater than the limit that is adaptively and dynamically calculated. This approach controls incoming SSL connections and prevents excessive resource consumption and other failures, such as load balancing monitoring failure or slow response to secure applications, on the appliance.

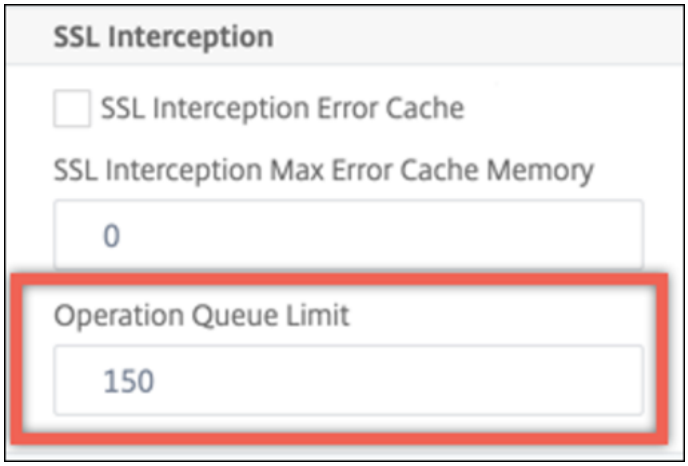
If the queue is empty, the appliance can continue to accept connections. If the queue is not empty, the crypto system has reached its capacity and the appliance starts queuing connections.

The limit is calculated based on:

- The actual capacity of the appliance.
- Value configured by the user as a percentage of the actual capacity. Default value is set to 150%.

For example, if the actual capacity of an appliance is 1000 operations/second at a given time and the default percentage is configured, the limit after which the appliance drops connections is 1500 (150% of 1000).

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



To configure the operation queue limit by using the CLI At the command prompt, type:

```
set ssl parameter -operationQueueLimit <positive_integer>
```

Operation Queue Limit - Limit in percentage of capacity of the crypto operations queue beyond which new SSL connections are not accepted until the queue is reduced. Default value: 150. Minimum value: 0. Maximum value: 10000.

To configure the operation queue limit by using the GUI

1. Navigate to **Traffic Management > SSL**.
2. In **Settings**, click **Change advanced SSL settings**.
3. Type a value in **Operation Queue Limit**. Default is 150.
4. Click **OK**.

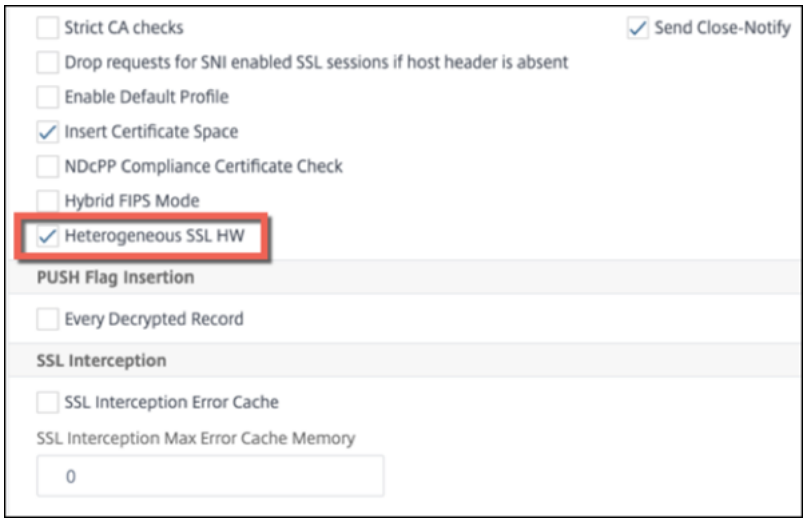
Heterogeneous cluster deployments

From release 13.0 build 47.x, you can form a heterogeneous cluster deployment of Citrix ADC MPX appliances with a different number of packet engines by setting the SSL parameter "Heterogeneous SSL HW"to ENABLED. For example, to form a cluster of Cavium chip based appliances (MPX 14000 or similar) and Intel Coleto chip based appliances (MPX 15000 or similar), enable the SSL parameter "Heterogeneous SSL HW."To form a cluster of platforms using the same chip, keep the default value (DISABLED) for this parameter.

> **Notes:**
>
> The following features are not supported in a heterogeneous cluster:
>
> - VPX instances hosted on Citrix ADC SDX appliances.
> - SSLv3 protocol on SSL entities, such as virtual server, services, service group, and internal

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> services.
> - Software crypto acceleration CPU threshold (using hardware and software to improve ECDSA and ECDHE cipher performance).



For more information about the platforms supported in a heterogeneous cluster, see https://docs.citrix.com/en-us/citrix-adc/13/clustering/support-for-heterogeneous-cluster.html.

Enable a heterogeneous cluster using the CLI At the command prompt, type:

```
set ssl parameter -heterogeneousSSLHW ENABLED
```

Enable a heterogeneous cluster using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **Settings** group, select **Change advanced SSL settings**.
2. Select **Heterogeneous SSL HW**. Click **OK**.

PUSH flag based encryption trigger mechanism

The encryption trigger mechanism that is based on the PSH TCP flag now enables you to do the following:

- Merge consecutive packets in which the PSH flag is set into a single SSL record, or ignore the PSH flag.
- Perform timer-based encryption, in which the time-out value is set globally by using the `set ssl parameter -pushEncTriggerTimeout <positive_integer>` command.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure PUSH flag-based encryption by using the CLI At the command prompt, type the following commands to configure PUSH flag-based encryption and verify the configuration:

```
set ssl vserver <vServerName> [-pushEncTrigger <pushEncTrigger>]

show ssl vserver
```

Example:

```
set ssl vserver vserver1 -pushEncTrigger always

Done

sh ssl vserver vserver1

            Advanced SSL configuration for VServer vserver1:
            DH: DISABLED
            DH Private-Key Exponent Size Limit: DISABLED    Ephemeral
               RSA: ENABLED

               Refresh Count: 0
            Session Reuse: ENABLED          Timeout: 120 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            ClearText Port: 0
            Client Auth: DISABLED

            Non FIPS Ciphers: DISABLED
            SNI: DISABLED
            OCSP Stapling: DISABLED
            HSTS: DISABLED
            HSTS IncludeSubDomains: NO
            HSTS Max-Age: 0
            SSLv2: DISABLED  SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1:
                ENABLED  TLSv1.2: ENABLED  TLSv1.3: DISABLED
            Push Encryption Trigger: Always
            Send Close-Notify: YES
            Strict Sig-Digest Check: DISABLED
            Zero RTT Early Data: DISABLED
            DHE Key Exchange With PSK: NO
            Tickets Per Authentication Context: 1
            ECC Curve: P_256, P_384, P_224, P_521

    1)      Cipher Name: DEFAULT
            Description: Default cipher list with encryption strength
               >= 128bit
Done
```

Configure PUSH flag-based encryption by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual servers** and open an SSL virtual

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

server.

2. In the **SSL Parameters** section, from the **PUSH Encryption Trigger** list, select a value.

Support for TLS1.2 signature hash algorithm

The Citrix ADC appliance is completely TLS1.2 signature hash extension compliant.

In an SSL handshake, a client sends a list of supported signature hash algorithms. The client indicates to the server which signature hash algorithm pairs might be used in the SSL handshake messages (SKE and CCV) by using the "signature_algorithms"extension. The "extension_data"field of this extension contains a "supported_signature_algorithms"value in the Client Hello message. The SSL handshake proceeds if the server supports one of these signature hash algorithms. If the server does not support any of these algorithms, the connection is dropped.

Similarly, if the server requests a client certificate for client authentication, the Certificate Request message contains a "supported_signature_algorithms"value. The client certificate is selected based on this signature hash algorithm.

> **Note:**
>
> The Citrix ADC appliance acts as a server to a client and as a client to the back-end server.

The appliance supports only RSA-SHA1 and RSA-SHA256 on the front end, and RSA-MD5, RSA-SHA1, and RSA-SHA256 on the back end.

The MPX/SDX/VPX appliance supports the following signature hash combinations. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies.

- On a VPX instance and on an MPX/SDX appliance without N3 chips:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384
  - RSA-SHA512
- On an MPX/SDX appliance with N3 chips:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- RSA-SHA512
- ECDSA-SHA1
- ECDSA-SHA224
- ECDSA-SHA256
- ECDSA-SHA384
- ECDSA-SHA512

By default, all the signature hash algorithms are enabled. However, you can enable only a few signature hash algorithms by using the following command:

```
set ssl parameter -sigDigestType <sigDigestType>

Parameters

sigDigestType

Signature digest algorithms supported by the appliance. The platform
   determines the list of algorithms supported by default.

             On VPX: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-SHA256 RSA-SHA384
                 RSA-

             SHA512

             On MPX with N3 cards: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-

             SHA256 RSA-SHA384 RSA-SHA512 ECDSA-SHA1 ECDSA-SHA224
                ECDSA-

             SHA256 ECDSA-SHA384 ECDSA-SHA512

             Other MPX Platforms: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-
                SHA256 RSA-SHA384 RSA-

             SHA512.

    set ssl parameter -sigDigestType RSA-SHA224 RSA-SHA256 RSA-SHA384
       RSA-SHA512
```

Validate the peer certificate According to RFC 5246, the peer certificate must be signed using one of the signature hash algorithms included in the Client Hello extension. You can use the `strictSigDigestCheck` parameter. Depending on the signature hash list sent by the client, if you enable `strictSigDigestCheck`, the appliance returns a certificate signed by one of the signature hash algorithms mentioned in the Client Hello extension. If the peer does not have a proper certificate, the connection is dropped. If this parameter is disabled, the signature hash is not checked in the peer certificate.

You can configure a strict signature digest check on an SSL virtual server and service. If you enable

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

this parameter on an SSL virtual server, the server certificate sent by the server must be signed by one of the signature hash algorithms listed in the Client Hello extension. If client authentication is enabled, then the client certificate received by the server must be signed using one of the signature hash algorithms listed in the certificate request sent by the server.

If you enable this parameter on an SSL service, the server certificate received by the client must be signed by one of the signature hash algorithms listed in the Client Hello extension. The client certificate must be signed using one of the signature hash algorithms listed in the certificate request message.

If the default profile is enabled, you can use it to configure a strict signature digest check on an SSL virtual server, SSL service, and SSL profile.

Configure strict signature digest check on an SSL virtual server, service, or profile by using the CLI At the command prompt, type:

```
set ssl vserver <vServerName> -strictSigDigestCheck ( ENABLED |
   DISABLED )

set ssl service <serviceName> -strictSigDigestCheck ( ENABLED |
   DISABLED )

set ssl profile <name>-strictSigDigestCheck ( ENABLED | DISABLED )

Parameters

strictSigDigestCheck

              Check whether peer entity certificate is signed using one
                  of the signature-hash algorithms supported by the
                 Citrix ADC appliance.

              Possible values: ENABLED, DISABLED

              Default: DISABLED
```

Example:

```
set ssl vserver v1 –strictSigDigestCheck Enabled
set ssl service s1 –strictSigDigestCheck Enabled
set ssl profile p1 –strictSigDigestCheck Enabled
```

> **Important:**
>
> If DH, ECDHE, or ECDSA ciphers are configured on the appliance, the SKE message must be signed using one of the signature-hashes common to the client list and the list configured on the appliance. If there is no common signature hash, the connection is dropped.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

TLSv1.3 protocol support as defined in RFC 8446

January 28, 2025

The Citrix ADC VPX and Citrix ADC MPX appliances now support the TLSv1.3 protocol, specified in RFC 8446.

> **Notes:**
>
> - From release 13.0 build 71.x and later, TLS1.3 hardware acceleration is supported on the following platforms:
>   - MPX 5900
>   - MPX/SDX 8900
>   - MPX/SDX 15000
>   - MPX/SDX 15000-50G
>   - MPX/SDX 26000
>   - MPX/SDX 26000-50S
>   - MPX/SDX 26000-100G
>   - Software-only support for the TLSv1.3 protocol is available on all other Citrix ADC MPX and SDX appliances except Citrix ADC FIPS appliances.
> - TLSv1.3 is only supported with the enhanced profile. To enable the enhanced profile, see Enable the enhanced profile.
> - To use TLS1.3, you must use a client that conforms to the RFC 8446 specification.

Supported Citrix ADC features

The following SSL features are supported:

1. TLSv1.3 cipher suites:
   - TLS1.3-AES256-GCM-SHA384 (0x1302)
   - TLS1.3_CHACHA20_POLY1305_SHA256 (0x1303)
   - TLS1.3-AES128_GCM-SHA256 (0x1301)
2. ECC curves for ephemeral Diffie-Hellman key exchange:
   - P_256
   - P_384

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- P_521

3. Abbreviated handshakes when ticket-based session resumption is enabled
4. 0-RTT early application data
5. Optional or mandatory certificate-based client authentication, with support for OCSP and CRL validation of client certificates
6. Server name extension: server certificate selection by using SNI
7. Application protocol negotiation (ALPN) by using the application_level_protocol_negotiation extension.
8. OCSP stapling
9. Log messages and AppFlow records are produced for TLSv1.3 handshakes.
10. Optional logging of TLS 1.3 traffic secrets by the `nstrace` packet capture utility.
11. Interoperability with TLS clients implementing RFC 8446. For example, Mozilla Firefox, Google Chrome, and OpenSSL.

Supported browsers

The following browser versions are supported and compatible with the Citrix ADC implementation oF TLS 1.3 protocol:

- Google Chrome - Version 72.0.3626.121 (Official Build) (64-bit)
- Mozilla Firefox - 65.0.2 (64-bit)
- Opera - Version:58.0.3135.79

Configuration

TLSv1.3 is disabled by default on an SSL profile.

Add an SSL profile by using the CLI

At the command prompt, type:

```
add ssl profile <tls13-profile-name>
```

Example:

```
add ssl profile tls13profile

sh ssl profile tls13profile
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
1)  Name: tls13profile           (Front-End)
    SSLv3: DISABLED               TLSv1.0: ENABLED  TLSv1.1: ENABLED
       TLSv1.2: ENABLED  TLSv1.3: DISABLED
    Client Auth: DISABLED
    Use only bound CA certificates: DISABLED
    Strict CA checks:   NO
    Session Reuse: ENABLED                      Timeout: 120 seconds
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED   Ephemeral RSA:
       ENABLED                              Refresh Count: 0

    Strict Host Header check for SNI enabled SSL sessions: NO
    Push flag:            0x0 (Auto)
    SSL quantum size:                            8 kB
    Encryption trigger timeout           100 mS
    Encryption trigger packet count:               45
    Subject/Issuer Name Insertion Format: Unicode

    SSL Interception: DISABLED
    SSL Interception OCSP Check: ENABLED
    SSL Interception End to End Renegotiation: ENABLED
    SSL Interception Maximum Reuse Sessions per Server:  10
    Session Ticket: DISABLED
    HSTS: DISABLED
    HSTS IncludeSubDomains: NO
    HSTS Max-Age: 0

    ECC Curve: P_256, P_384, P_224, P_521

1)  Cipher Name: DEFAULT Priority :1
    Description: Predefined Cipher Alias
Done
```

Add an SSL profile by using the GUI

1. Navigate to **System > Profiles**. Select **SSL Profiles**.
2. Click **Add** and specify a name for the profile.
3. In **Protocol**, select **TLSv13**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. Click **OK**.

Bind an SSL profile to an SSL virtual server by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName> -sslProfile <tls13-profile-name>
```

Example:

```
set ssl vserver ssl-vs -sslProfile tls13profile
```

Bind an SSL profile to an SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select an SSL virtual server.
2. In **Advanced Settings**, click **SSL Profile**.
3. Select the TLSv1.3 profile created earlier.
4. Click **OK**.
5. Click **Done**.

SSL profile parameters for TLSv1.3 protocol

1. Enable or disable TLS1.3 parameters in an SSL profile.

   tls13: State of TLSv1.3 protocol support for the SSL profile.

   Possible values: ENABLED, DISABLED

   Default value: DISABLED

   ```
   set ssl profile tls13profile -tls13 enable
   ```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set ssl profile tls13profile -tls13 disable
```

2. Set number of session tickets issued.

   tls13SessionTicketsPerAuthContext: Number of tickets the SSL virtual server issues when TLS1.3 is negotiated, ticket-based resumption is enabled, and either (1) a handshake completes or (2) client authentication completes after the handshake.

   This value can be increased to enable clients to open multiple parallel connections using a fresh ticket for each connection.

   No tickets are sent if resumption is disabled.

   Default value: 1

   Minimum value: 1

   Maximum value: 10

```
set ssl profile tls13profile -tls13sessionTicketsPerAuthContext 1

set ssl profile tls13profile -tls13sessionTicketsPerAuthContext 10
```

3. Set DH key exchange

   dheKeyExchangeWithPsk: Specifies whether an SSL virtual server requires a DHE key exchange to occur when a preshared key is accepted during a TLS 1.3 session resumption handshake. A DHE key exchange ensures forward secrecy, even if ticket keys are compromised, at the expense of extra resources required to carry out the **DHE** key exchange.

   Available settings work as follows, if the session ticket is enabled:

   YES: DHE key exchange is required when a pre-shared key is accepted, regardless of whether the client supports the key exchange. The handshake is aborted with a fatal alert, if the client does not support DHE key exchange when offering a pre-shared key.

   NO: DHE key exchange is performed when a pre-shared key is accepted, only if requested by the client.

   Possible values: YES, NO

   Default value: NO

```
set ssl profile tls13profile dheKeyExchangeWithPsk yes

set ssl profile tls13profile dheKeyExchangeWithPsk no
```

4. Enable or disable 0-RTT early data acceptance

   zeroRttEarlyData: State of TLS 1.3 early application data. Applicable settings work as follows:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

ENABLED: Early application data might be processed before the handshake is complete.
DISABLED: Early application data is ignored.

Possible values: ENABLED, DISABLED

Default value: DISABLED

```
set ssl profile tls13profile -zeroRttEarlyData ENABLED

set ssl profile tls13profile -zeroRttEarlyData DISABLED
```

Default cipher group

The default cipher group includes TLS1.3 ciphers.

```
sh cipher DEFAULT
1) Cipher Name: TLS1-AES-256-CBC-SHA    Priority : 1
    Description: SSLv3 Kx=RSA      Au=RSA  Enc=AES(256)  Mac=SHA1
       HexCode=0x0035

2)  Cipher Name: TLS1-AES-128-CBC-SHA    Priority : 2
    Description: SSLv3 Kx=RSA      Au=RSA  Enc=AES(128)  Mac=SHA1
       HexCode=0x002f
...
...
27) Cipher Name: TLS1.3-AES256-GCM-SHA384         Priority : 27
    Description: TLSv1.3 Kx=any      Au=any  Enc=AES-GCM(256) Mac=AEAD
         HexCode=0x1302

28) Cipher Name: TLS1.3_CHACHA20_POLY1305_SHA256     Priority : 28
    Description: TLSv1.3 Kx=any      Au=any  Enc=CHACHA20/POLY1305(256)
        Mac=AEAD   HexCode=0x1303

29) Cipher Name: TLS1.3-AES128_GCM-SHA256        Priority : 29
    Description: TLSv1.3 Kx=any      Au=any  Enc=AES-GCM(128) Mac=AEAD
         HexCode=0x1301
Done
```

Limitations

- TLSv1.3 is not supported on the back end.
- TLSv1.3 is not supported on a Citrix Secure Web Gateway appliance and on a Citrix ADC FIPS appliance.
- Only RSA certificates with 1024-bit and larger keys are supported in a TLSv1.3 handshake.
- Prior to release 14.1 build 3.4, TLSv1.3 handshake logs are not captured even if the debug level was set.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Security restrictions

TLSv1.3 server operators must keep in mind the following security restrictions for backward compatibility outlined in RFC 8446. The default configuration on a NetScaler appliance is compliant with these restrictions. However, a NetScaler appliance does not enforce that these rules are adhered to.

- The security of RC4 cipher suites is considered insufficient as described in RFC7465. Implementations must not offer or negotiate RC4 cipher suites for any version of TLS.
- Old versions of TLS allowed the use of low strength ciphers. Ciphers with a strength less than 112 bits must not be offered or negotiated for any version of TLS.
- The security of SSL 3.0 [SSLv3] is considered insufficient as described in RFC7568, and must not be negotiated. Disable SSLv3 when TLSv1.3 is enabled (SSLv3 is disabled by default.)
- The security of SSL 2.0 [SSLv2] is considered insufficient as described in RFC6176, and must not be negotiated. Disable SSLv2 when TLS 1.3 is enabled (SSLv2 is disabled by default.)

> **Note:**
>
> For information about troubleshooting protocols that run over TLS1.3, see Decrypting TLS1.3 traffic from packet trace.

How-to articles

September 14, 2021

How-to articles are simple and easy to use articles with configuration steps for common deployments. Click a link to view the article.

Create a certificate signing request and use SSL certificates on a Citrix ADC appliance

Configure SSL action to forward client traffic

Configure SSL action to forward client traffic if a cipher is not supported on the ADC

Configure per directory client authentication

Configure support for Outlook web access

Configure SSL based header insertion

Configure SSL offloading with end-to-end encryption

Configure transparent SSL acceleration

Configure SSL offloading with other TCP protocols

Configure SSL bridging

Configure SSL monitoring when client authentication is enabled on the back-end service

Configure a secure content switching server

Configure an HTTPS virtual server to accept HTTP traffic

Configure graceful cleanup of SSL sessions

Configure support for HTTP strict transport security (HSTS)

Configure SSLv2 redirection

Configure synchronization of files in a high availability setup

Disable TLS 1.0 and TLS 1.1 on NSIP

Export certificates used on the Citrix ADC appliance as PFX file

SSL certificates

September 14, 2021

An SSL certificate, which is a part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. The certificate has a public key component that is visible to any client that wants to initiate a secure transaction with the server. The corresponding private key, which resides securely on the Citrix ADC appliance, is used to complete asymmetric key (or public key) encryption and decryption.

You can obtain an SSL certificate and key in either of the following ways:

- From an authorized certificate authority (CA), such as Verisign
- By generating a new SSL certificate and key on the Citrix ADC appliance

Alternately, you can use an existing SSL certificate on the appliance.

Certificates are categorized into four types by the Citrix ADC appliance:

- **Server certificates:** A server certificate authenticates the server's identity to the client. On the front-end, the ADC appliance acts as a server. You bind a server certificate and a private key to an SSL virtual server on the ADC appliance.
- **Client certificates:** A client certificate authenticates the client's identity to the server. On the back-end, the ADC appliance acts as a client. You bind a client certificate and private key to the SSL service or service group on the ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- **CA certificates:** CA certificates issue the end-user certificates (client and server certificates). A CA certificate can be a trusted root CA (self-signed by the certificate authority) or an intermediate CA (signed by a trusted root CA). Typically, CA certificates do not need private keys.
- **Unknown certificates:** All other certificates fall in this category.

Important: Citrix recommends that you use certificates obtained from authorized CAs, such as Verisign, for all your SSL transactions. Use certificates generated on the Citrix ADC appliance for testing purposes only, not in any live deployment.

- If while adding a certificate-key pair, you add a certificate file with the same name as an existing certificate file, the original certificate file is overwritten with no warning. This action might cause issues after the appliance is restarted because the original certificate file is no longer available in the `/nsconfig/ssl` directory.
- Removing any certificate or key files in a cluster environment restricts further configuration on the ADC appliance. Add the files back at the same location to make any configuration changes.

Note: You can use the ADM SSL dashboard for ease of SSL certificate management and set notifications for certificates that are unused or soon to expire. For more information, see SSL certificate management.

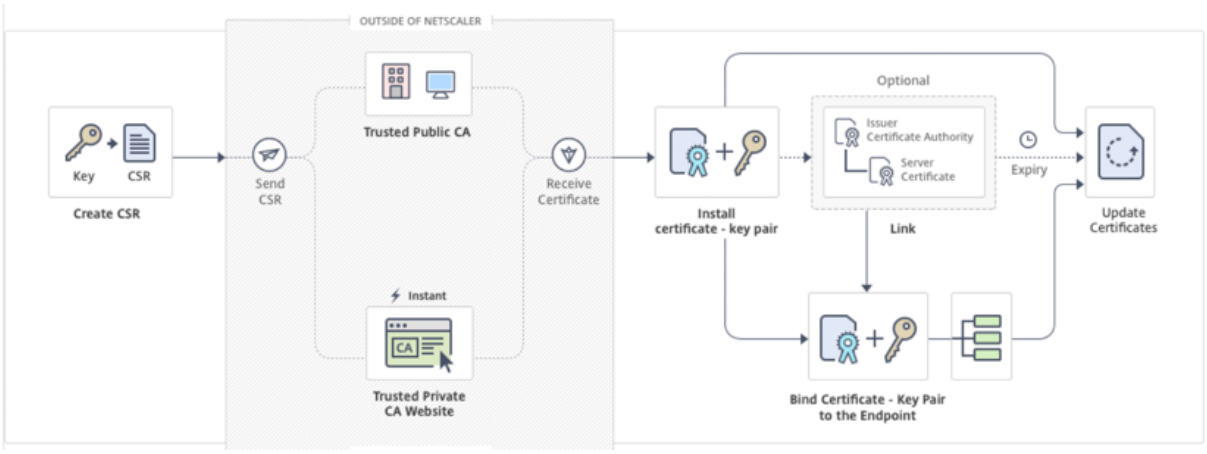
Create a certificate

July 25, 2023

A certificate authority (CA) is an entity that issues digital certificates for use in public key cryptography. Applications, such as web browsers, that conduct SSL transactions trust certificates issued or signed by a Certificate Authority. These applications maintain a list of the CAs that they trust. If any of the trusted CAs sign the certificate being used for the secure transaction, the application proceeds with the transaction.

Caution: Citrix recommends that you use certificates obtained from authorized CAs, such as Verisign, for all your SSL transactions. Use certificates generated on the Citrix ADC appliance for testing purposes only, not in any live deployment.

To import an existing certificate and key, see Import a Certificate.



Perform the following steps to create a certificate and bind it to an SSL virtual server. The only special characters allowed in the file names are underscore and dot.

- Create a private key.
- Create a certificate signing request (CSR).
- Submit the CSR to a certificate authority.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Create a certificate-key pair.
- Bind the certificate-key pair to an SSL virtual server

The following diagram illustrates the workflow.

How to create and install a new certificate

This is an embedded video. Click the link to watch the video

Create a private key

> **Notes:**
>
> - From release 12.1 build 49.x, you can use the AES256 algorithm with PEM key format to encrypt a private key on the appliance. AES with 256-bit key is more mathematically efficient and secure compared to the 56-bit key of the Data Encryption Standard (DES).
> - From release 12.1 build 50.x, you can create an RSA key in PKCS#8 format.

The private key is the most important part of a digital certificate. By definition, this key is not to be shared with anyone and must be kept securely on the Citrix ADC appliance. Any data encrypted with the public key can be decrypted only by using the private key.

The certificate that you receive from the CA is valid only with the private key that was used to create the CSR. The key is required for adding the certificate to the Citrix ADC appliance.

The appliance supports only the RSA encryption algorithms for creating private keys. You can submit either type of private key to the certificate authority (CA). The certificate that you receive from the CA is valid only with the private key that was used to create the CSR. The key is required for adding the certificate to the Citrix ADC appliance.

Important:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

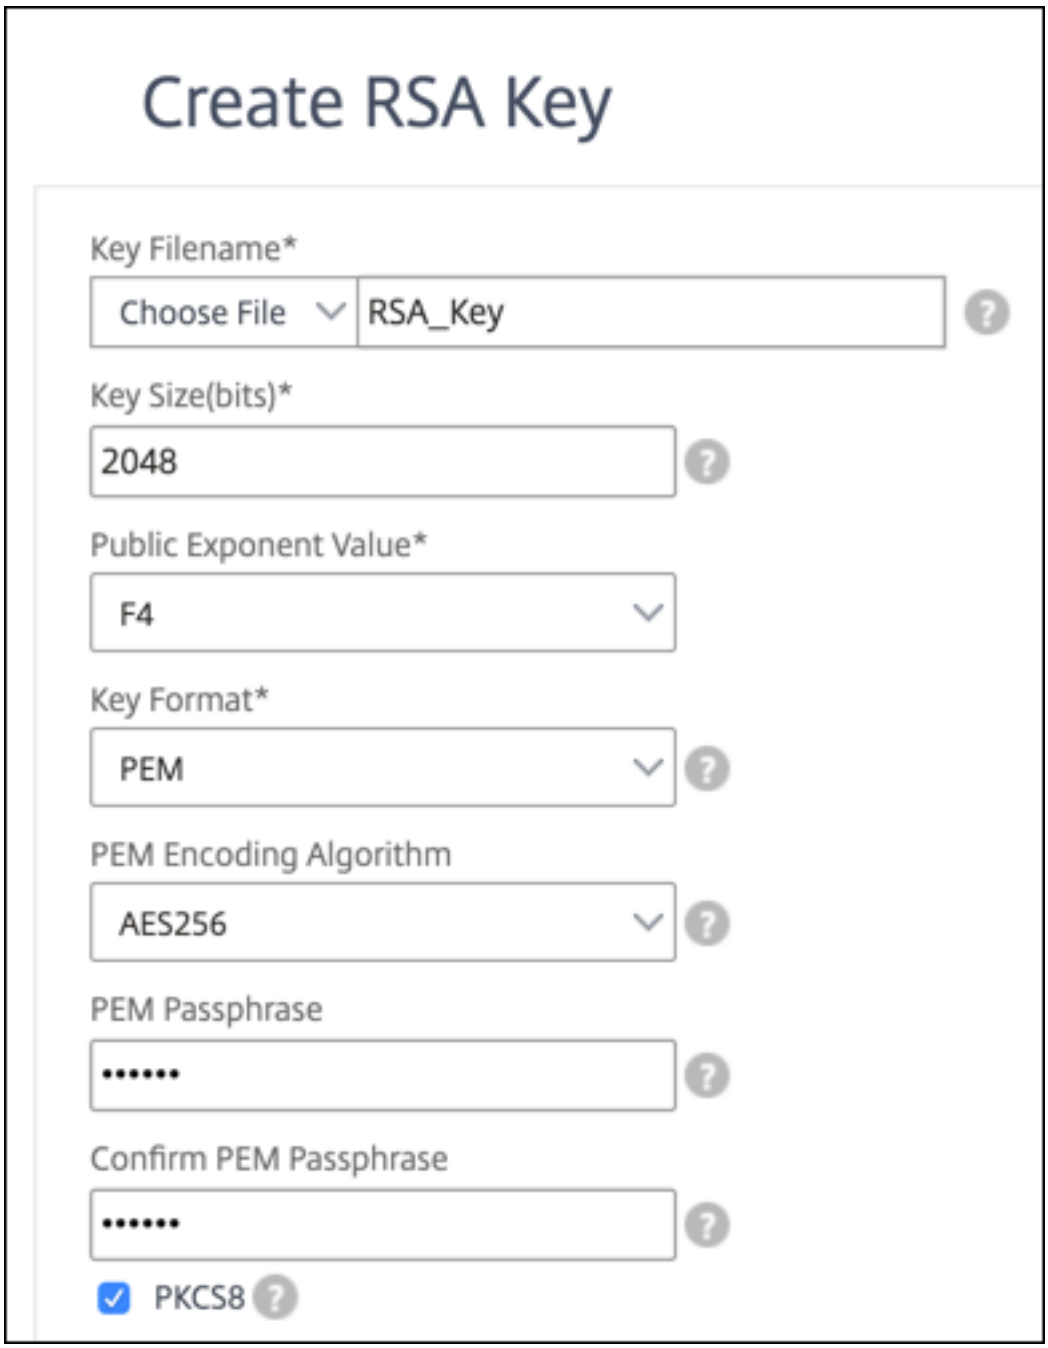
> - Be sure to limit access to your private key. Anyone who has access to your private key can decrypt your SSL data.
> - The length of the SSL key name allowed includes the length of the absolute path name if the path is included in the key name.

All SSL certificates and keys are stored in the /nsconfig/ssl folder on the appliance. For added security, you can use the DES or triple DES (3DES) algorithm to encrypt the private key stored on the appliance.

Create an RSA private key by using the CLI

At the command prompt, type:

```
create ssl rsakey <keyFile> <bits> [-exponent ( 3 | F4 )] [-keyform (
   DER | PEM )] [-des | -des3 | -aes256] {
 -password  }
  [-pkcs8]
```



Example:

```
create rsakey testkey 2048 -aes256 -password 123456 -pkcs8
```

Create an RSA private key by using the GUI

1. Navigate to **Traffic Management > SSL > SSL Files**.
2. In the **Keys** tab, select **Create RSA Key**.
3. Enter values for the following parameters and click **Create**.
   - **Key Filename** - Name for and, optionally, path to the RSA key file. /nsconfig/ssl/ is the default path.
   - **Key Size** - Size, in bits, of the RSA key. Can range from 512 bits to 4096 bits.
   - **Public Exponent Value** - Public exponent for the RSA key. The exponent is part of the cipher algorithm and is required for creating the RSA key.
   - **Key Format** - The format in which the RSA key file is stored on the appliance.
   - **PEM Encoding Algorithm** - Encrypt the generated RSA key by using the AES 256, DES, or Triple-DES (DES3) algorithm. By default, private keys are unencrypted.
   - **PEM Passphrase** - If the private key is encrypted, enter a pass phrase for the key.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Select an AES256 encoding algorithm in an RSA key by using the GUI

1. Navigate to **Traffic Management > SSL > SSL Files > Create RSA Key**.
2. In **Key Format**, select **PEM**.
3. In **PEM Encoding Algorithm**, select **AES256**.
4. Select **PKCS8**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Create a certificate signing request by using the CLI

At the command prompt, type:

```
create ssl certreq <reqFile> -keyFile <input_filename> | -fipsKeyName <string>) [-keyForm (DER | PEM) {
 -PEMPassPhrase  }
 ] -countryName <string> -stateName <string> -organizationName <string> -organizationUnitName <string> -localityName <string> -commonName <string> -emailAddress <string> {
 -challengePassword  }
  -companyName <string> -digestMethod ( SHA1 | SHA256 )
```

Example:

```
create ssl certreq priv_csr_sha256 -keyfile priv_2048_2 -keyform PEM -countryName IN -stateName Karnataka -localityName Bangalore -organizationName Citrix -organizationUnitName NS -digestMethod SHA256
```

Create a certificate signing request by using the GUI

1. Navigate to **Traffic Management > SSL**.
2. In **SSL** Certificate, click **Create Certificate Signing Request (CSR)**.
3. In **Digest** Method, select **SHA256**.

See Create a CSR for more information.

Support for subject alternative name in a certificate signing request

The subject alternative name (SAN) field in a certificate allows you to associate multiple values, such as domain names and IP addresses, with a single certificate. In other words, you can secure multiple domains, such as www.example.com, www.example1.com, www.example2.com, with a single certificate.

Some browsers, such as Google Chrome, no longer support a common name in a certificate signing request (CSR). They enforce SAN in all publicly trusted certificates.

The Citrix ADC appliance supports adding SAN values when creating a CSR. You can send a CSR with a SAN entry to a certificate authority to obtain a signed certificate with that SAN entry. When the appliance receives a request, it checks for a matching domain name in the SAN entries in the server certificate. If a match is found, it sends the certificate to the client and completes the SSL handshake. You can use the CLI or the GUI to create a CSR with SAN values.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note:** The Citrix ADC appliance processes only DNS based SAN values.

Create a CSR with the subject alternative name by using the CLI

```
create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName
   <string>) [-subjectAltName <string>] [-keyform ( DER | PEM )  {
-PEMPassPhrase  }
] -countryName <string> -stateName <string> -organizationName <string>
    [-organizationUnitName <string>] [-localityName <string>] [-
   commonName <string>] [-emailAddress <string>] {
-challengePassword  }
 [-companyName <string>] [-digestMethod ( SHA1 | SHA256 )]
```

Parameters:

subjectAltName: The subject alternative name (SAN) is an extension to X.509 that allows various values to be associated with a security certificate using a subjectAltName field. These values are called "Subject Alternative Names"(SAN). Names include:

1. IP addresses (Prefix with "IP:"Example: IP:198.51.10.5 IP:192.0.2.100)
2. DNS names (Prefix with "DNS:"Example: DNS:www.example.com DNS:www.example.org DNS:www.example.net)

On the command line, enter values within quotation marks. Separate two values with a space. Quotation marks are not required in the GUI.
Maximum Length: 127

Example:

```
create certReq test1.csr -keyFile test1.ky -countryName IN -stateName
   Kar -organizationName citrix -commonName ctx.com -subjectAltName "
   DNS:*.example.com DNS:www.example.org DNS:www.example.net"
```

> **Note:**
>
> On a FIPS appliance, you must replace the key file name with the FIPS key name if you create the FIPS key directly on the appliance.
>
> ```
> create certReq <csrname> -fipsKeyName fipskey.ky -countryName IN -
>    stateName Kar -organizationName citrix -commonName ctx.com -
>    subjectAltName "DNS:www.example.com DNS:www.example.org DNS:www.
>    example.net"
> ```

Create a CSR by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **SSL Files**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. In the **CSR** tab, click **Create Certificate Signing Request (CSR)**.
3. Enter the values and click **Create**.

Limitations

To use SAN when creating an SSL certificate, you must explicitly specify the SAN values. The values are not read automatically from the CSR file.

Submit the CSR to the Certificate Authority

Most certificate authorities (CA) accept certificate submissions by email. The CA returns a valid certificate to the email address from which you submit the CSR.

The CSR is stored in the `/nsconfig/ssl` folder.

Generate a test certificate

> **Note:**
>
> To generate a server test certificate, see Generating a Server Test Certificate.

The Citrix ADC appliance has a built-in CA tools suite that you can use to create self-signed certificates for testing purposes.

Caution: Because the Citrix ADC appliance signs these certificates, and not an actual CA, you must not use them in a production environment. If you attempt to use a self-signed certificate in a production environment, users receive a "certificate invalid"warning each time the virtual server is accessed.

The appliance supports creation of the following types of certificates

- Root-CA certificates
- Intermediate-CA certificates
- End-user certificates
  - server certificates
  - client certificates

Before generating a certificate, create a private key and use that to create a certificate signing request (CSR) on the appliance. Then, instead of sending the CSR out to a CA, use the Citrix ADC CA Tools to generate a certificate.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Create a certificate by using a wizard

1. Navigate to **Traffic Management > SSL**.
2. In the details pane, under **Getting Started**, select the wizard for the type of certificate that you want to create.
3. Follow the instructions on the screen.

Create a root-CA certificate by using the CLI

At the command prompt, type the following command:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <
    input_filename>] [-keyform ( DER | PEM )] [-days <positive_integer>]
```

In the following example, csreq1 is the CSR and rsa1 is the private key that was created earlier.

Example:

```
create ssl cert cert1 csreq1 ROOT_CERT -keyFile rsa1 -keyForm PEM -days
    365

  Done
```

Create an intermediate-CA certificate by using the CLI

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <
    input_filename>] [-keyform ( DER | PEM )] [-days <positive_integer>]
     [-certForm ( DER | PEM )] [-CAcert <input_filename>] [-CAcertForm (
     DER | PEM )] [-CAkey <input_filename>] [-CAkeyForm ( DER | PEM )]
    [-CAserial <output_filename>]
```

In the following example, csr1 is the CSR created earlier. Cert1 and rsakey1 are the certificate and corresponding key of the self-signed (root-CA) certificate, and pvtkey1 is the private key of the intermediate-CA certificate.

Example:

```
create ssl cert certsy csr1 INTM_CERT -CAcert cert1 -CAkey rsakey1 -
    CAserial 23
Done

create ssl rsakey pvtkey1 2048 -exponent F4 -keyform PEM
Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Create a root-CA certificate by using the GUI

Navigate to **Traffic Management > SSL** and, in the Getting Started group, select **Root-CA Certificate Wizard**, and configure a root CA certificate.

Create an intermediate-CA certificate by using the GUI

Navigate to **Traffic Management > SSL** and, in the Getting Started group, select **Intermediate-CA Certificate Wizard**, and configure an intermediate CA certificate.

Create an end-user certificate

An end-user certificate can be a client certificate or a server certificate. To create a test end-user certificate, specify the Intermediate CA certificate or the self-signed root-CA certificate.

> **Note:** To create an end-user certificate for production use, specify a trusted CA certificate and send the CSR to a certificate authority (CA).

Create a test end-user certificate by using the command line interface

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <
    input_filename>] [-keyform ( DER | PEM )] [-days<positive_integer>]
    [-certForm ( DER | PEM )] [-CAcert <input_filename>] [-CAcertForm (
    DER | PEM )] [-CAkey<input_filename>] [-CAkeyForm ( DER | PEM )] [-
    CAserial <output_filename>]
```

If there is no intermediate certificate, use the certificate (cert1) and private key (rsakey1) values of the root-CA certificate in `CAcert` and `CAkey`.

Example:

```
create ssl cert cert12 csr1 SRVR_CERT -CAcert cert1 -CAkey rsakey1 -
    CAserial 23

Done
```

If there is an intermediate certificate, use the certificate (`certsy`) and private key (pvtkey1) values of the intermediate certificate in `CAcert` and `CAkey`.

Example:

```
create ssl cert cert12 csr1 SRVR_CERT -CAcert certsy -CAkey pvtkey1 -
    CAserial 23

Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Create a self-signed SAN Certificate using OpenSSL

To create a self-signed SAN certificate with multiple subject alternate names, perform the following steps:

1. Create an OpenSSL configuration file on your local computer by editing the fields related as per the company requirements.

   Note: In the following example, the configuration file is "req.conf".

```
[req]
distinguished_name = req_distinguished_name
x509_extensions = v3_req
prompt = no
[req_distinguished_name]
C = US
ST = VA
L = SomeCity
O = MyCompany
OU = MyDivision
CN = www.company.com
[v3_req]
keyUsage = keyEncipherment, dataEncipherment
extendedKeyUsage = serverAuth
subjectAltName = @alt_names
[alt_names]
DNS.1 = www.company.net
DNS.2 = company.com
DNS.3 = company.net
```

2. Upload the file to the /nsconfig/ssl directory on the Citrix ADC appliance.
3. Log on to Citrix ADC CLI as `nsroot` user and switch to the shell prompt.
4. Run the following command to create the certificate:

```
cd /nsconfig/ssl
openssl req -x509 -nodes -days 730 -newkey rsa:2048 -keyout cert.
   pem -out cert.pem -config req.conf -extensions 'v3_req'
```

5. Run the following command to verify the certificate:

```
openssl x509 -in cert.pem -noout  – text
Certificate:
Data:
Version: 3 (0x2)
Serial Number:
ed:90:c5:f0:61:78:25:ab
Signature Algorithm: md5WithRSAEncryption
Issuer: C=US, ST=VA, L=SomeCity, O=MyCompany, OU=MyDivision, CN=
   www.company.com
Validity
Not Before: Nov 6 22:21:38 2012 GMT
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
Not After : Nov 6 22:21:38 2014 GMT
Subject: C=US, ST=VA, L=SomeCity, O=MyCompany, OU=MyDivision, CN=
   www.company.com
Subject Public Key Info:
Public Key Algorithm: rsaEncryption
RSA Public Key: (2048 bit)
Modulus (2048 bit):
...
Exponent: 65537 (0x10001)
X509v3 extensions:
X509v3 Key Usage:
Key Encipherment, Data Encipherment
X509v3 Extended Key Usage:
TLS Web Server Authentication
X509v3 Subject Alternative Name:
DNS:www.company.net, DNS:company.com, DNS:company.net
Signature Algorithm: md5WithRSAEncryption ...
```

Install, link, and update certificates

December 29, 2023

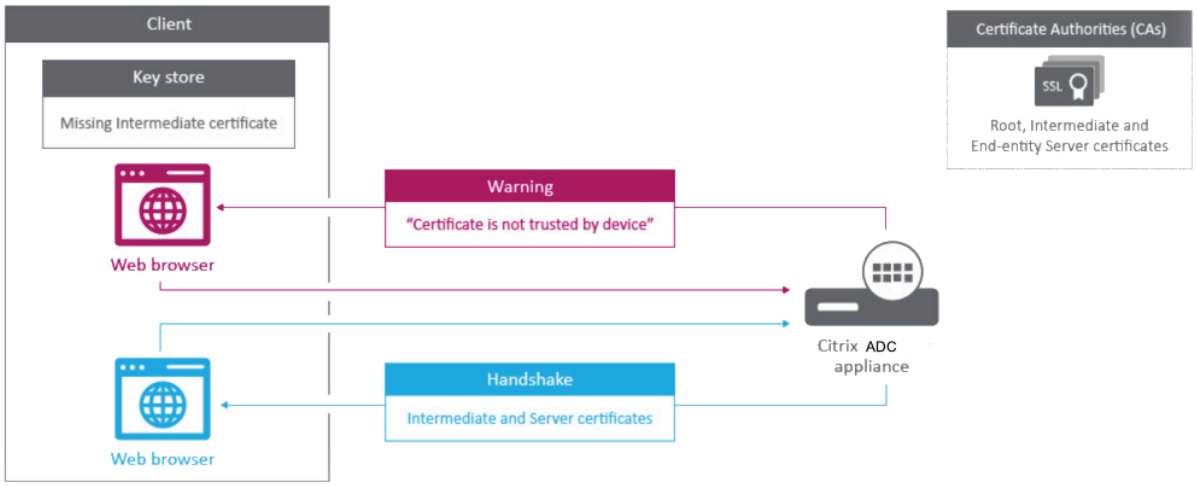
To install a certificate, see Add or update a certificate-key pair.

Link certificates

Many server certificates are signed by multiple hierarchical Certificate Authorities (CA), which means that the certificates form a chain like the following:

```
Root CA
|
+---------- Intermediate CA
|
+---------------------- End-Entity (Server) Certificate
```

Sometimes, the Intermediate CA is split into a primary and secondary intermediate CA certificate. Then the certificates form a chain like the following:



```
Root CA
|
+------ Primary Intermediate CA
|+-------------- Secondary Intermediate CA
|
+---------------------- End-Entity (Server) Certificate
```

Client machines usually contain the root CA certificate in their local certificate store, but not one or more intermediate CA certificates. The ADC appliance must send one or more intermediate CA certificates to the clients.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: The appliance must not send the root CA certificate to the client. The Public Key Infrastructure (PKI) trust relationship model requires root CA certificates to be installed on clients through an out-of-band method. For example, the certificates are included with the operating system or web browser. The client ignores a root CA certificate sent by the appliance.

Sometimes, an intermediate CA that standard web browsers do not recognize as a trusted CA, issues the server certificate. In this case, one or more CA certificates must be sent to the client with the server's own certificate. Otherwise, the browser terminates the SSL session because it fails to authenticate the server certificate.

Refer to the following sections to add the server and intermediate certificates:

- Manual certificate linking
- Automated certificate linking
- Create a chain of certificates

How to link an intermediate authority certificate

This is an embedded video. Click the link to watch the video

Manual certificate linking

Note: This feature is not supported on the Citrix ADC FIPS platform and in a cluster setup.

Instead of adding and linking individual certificates, you can now group a server certificate and up to nine intermediate certificates in a single file. You can specify the file's name when adding a certificate-key pair. Before you do so, make sure that the following prerequisites are met.

- The certificates in the file are in the following order:
  - Server certificate (must be the first certificate in the file)

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

  - Optionally, a server key
  - Intermediate certificate 1 (ic1)
  - Intermediate certificate 2 (ic2)
  - Intermediate certificate 3 (ic3), and so on
    Note: Intermediate certificate files are created for each intermediate certificate with the name "<certificatebundlename>.pem_ic<
    n>"where n is between 1 and 9. For example, bundle.pem_ic1, where **bundle** is the name of the certificate set and ic1 is the first intermediate certificate in the set.

- Bundle option is selected.
- No more than nine intermediate certificates are present in the file.

The file is parsed and the server certificate, intermediate certificates, and server key (if present) are identified. First, the server certificate and key are added. Then, the intermediate certificates are added, in the order in which they were added to the file, and linked accordingly.

An error is reported if any of the following conditions exist:

- A certificate file for one of the intermediate certificates exists on the appliance.
- The key is placed before the server certificate in the file.
- An intermediate certificate is placed before the server certificate.
- Intermediate certificates are not in placed in the file in the same order as they are created.
- No certificates are present in the file.
- A certificate is not in the proper PEM format.
- The number of intermediate certificates in the file exceeds nine.

Add a certificate set by using the CLI

At the command prompt, type the following commands to create a certificate set and verify the configuration:

```
add ssl certKey <certkeyName> -cert <string> -key <string> -bundle (YES
    | NO)

show ssl

show ssl certlink
```

In the following example, the certificate set (bundle.pem) contains the following files:

Server certificate (bundle) linked to bundle_ic1

First intermediate certificate (bundle_ic1) linked to bundle_ic2

Second intermediate certificate (bundle_ic2) linked to bundle_ic3

Third intermediate certificate (bundle_ic3)

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add ssl certKey bundletest -cert bundle9.pem -key bundle9.pem -bundle
   yes

sh ssl certkey

1)      Name: ns-server-certificate
        Cert Path: ns-server.cert
        Key Path: ns-server.key
        Format: PEM
        Status: Valid,   Days to expiration:5733
        Certificate Expiry Monitor: ENABLED
        Expiry Notification period: 30 days

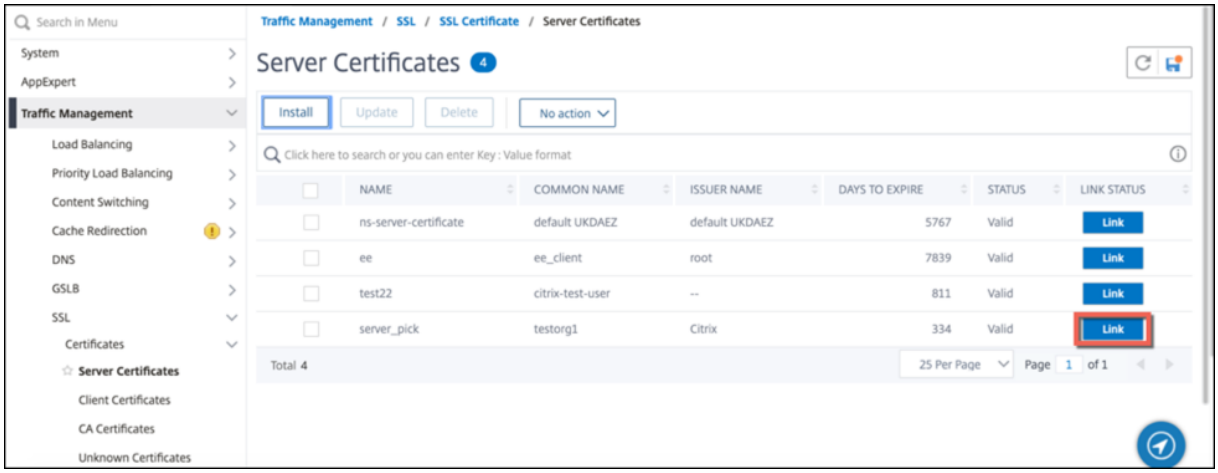
Add a certificate set by using the GUI



1. Navigate to **Traffic Management** > **SSL** > **Certificates** > **CA Certificates**.
2. In the details pane, click **Install**.
3. In the **Install Certificate** dialog box, type the details, such as the certificate and key file name, and then select **Certificate Bundle**.
4. Click **Install**, and then click **Close**.

Automated certificate linking

Note: This feature is available from release 13.0 build 47.x.

You no longer have to manually link a certificate to its issuer all the way to the root certificate. If the intermediate CA certificates and the root certificate are present on the appliance, you can click the **Link** button in the end user certificate.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

The potential chain appears.

Click **Link Certificate** to link all the certificates.

Create a chain of certificates

Instead of using a set of certificates (a single file), you can create a chain of certificates. The chain links the server certificate to its issuer (the intermediate CA). This approach requires that the intermediate CA certificate file is installed on the ADC appliance, and the client application must trust one of the certificates in the chain. For example, link Cert-Intermediate-A to Cert-Intermediate-B, where Cert-Intermediate-B is linked to Cert-Intermediate-C, which is a certificate trusted by the client application.

Note: The appliance supports sending a maximum of 10 certificates in the chain of certificates sent to the client (one server certificate and nine CA certificates).

Create a certificate chain by using the CLI

At the command prompt, type the following commands to create a certificate chain and verify the configuration. (Repeat the first command for each new link in the chain.)

```
link ssl certkey <certKeyName> <linkCertKeyName>
show ssl certlink
```

Example:

```
link ssl certkey siteAcertkey CAcertkey
Done

show ssl certlink

linked certificate:
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
        1) Cert Name: siteAcertkey CA Cert Name: CAcertkey
Done
```

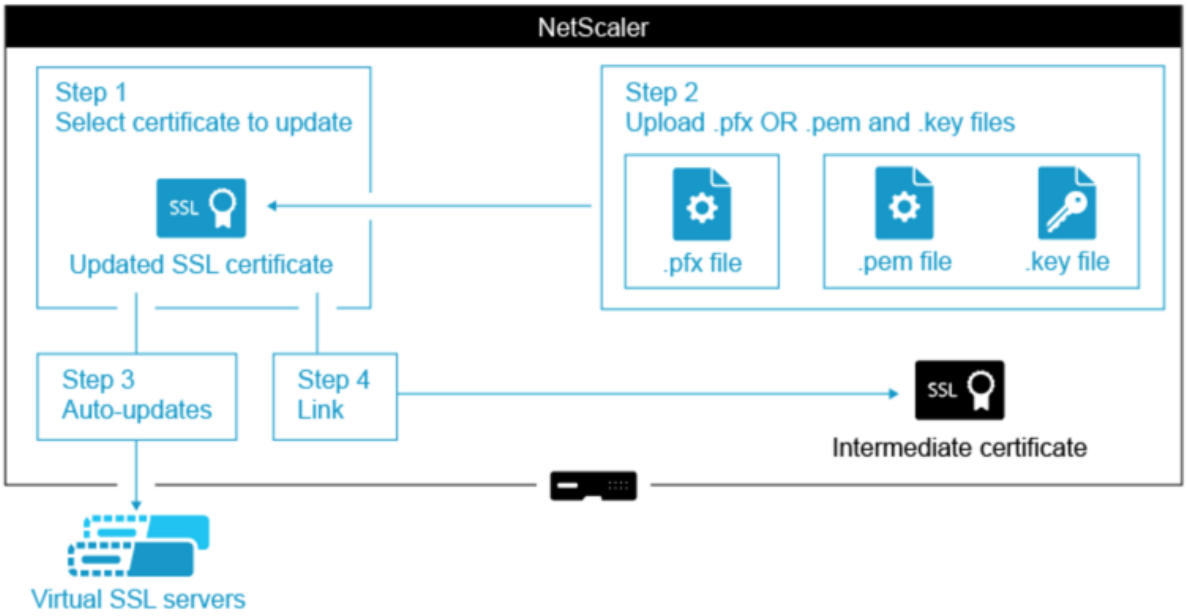
Create a certificate chain by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Certificates**.
2. Select a server certificate, and in the **Action** list, select **Link**, and specify a CA certificate name.

Update an existing server certificate

To change an existing server certificate manually, you must perform the following steps:

1. Unbind the old certificate from the virtual server.
2. Remove the certificate from the appliance.
3. Add the new certificate to the appliance.
4. Bind the new certificate to the virtual server.



To reduce downtime when replacing a certificate-key pair, you can update an existing certificate. If you want to replace a certificate with a certificate that was issued to a different domain, you must disable domain checks before updating the certificate.

To receive notifications about certificates due to expire, you can enable the expiry monitor.

When you remove or unbind a certificate from a configured SSL virtual server or service, the virtual server or service becomes inactive. They are active after a new valid certificate is bound to them. To reduce downtime, you can use the update feature to replace a certificate-key pair that is bound to an SSL virtual server or an SSL service.

Overview diagram of how to update an SSL certificate on the Citrix ADC appliance.

How to update an existing certificate

This is an embedded video. Click the link to watch the video

Update an existing certificate-key pair by using the CLI

At the command prompt, type the following commands to update an existing certificate-key pair and verify the configuration:

```
update ssl certkey <certkeyName> -cert <string> -key <string>

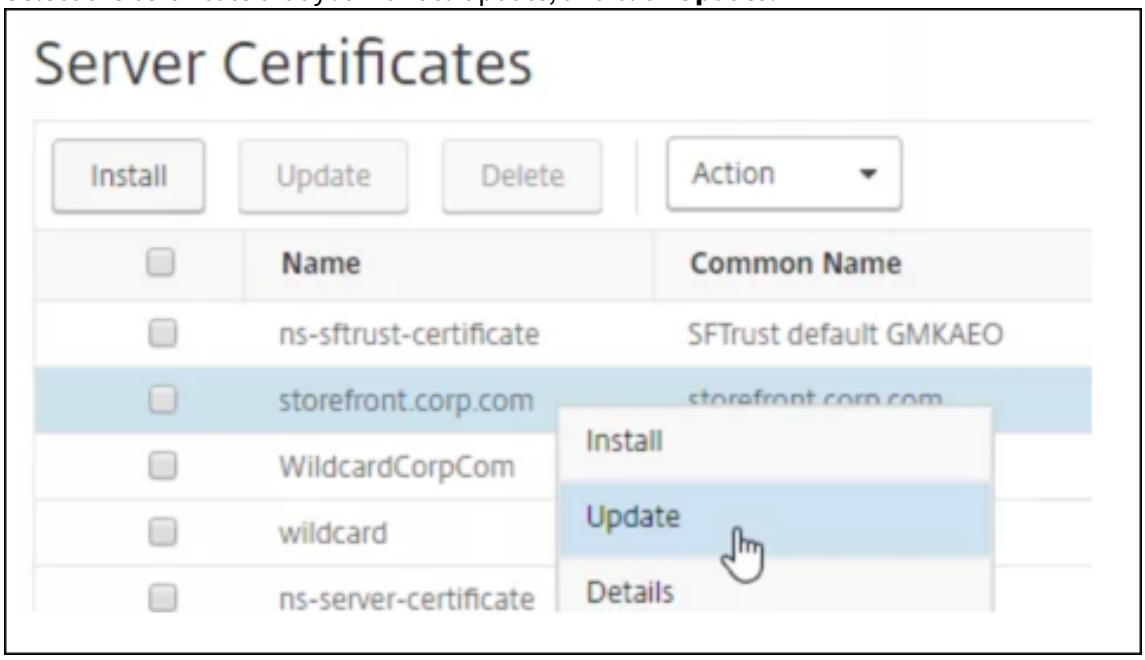
show ssl certKey <certkeyName>
```

Example:

```
update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /
   nsconfig/ssl/pkey.pem

Done

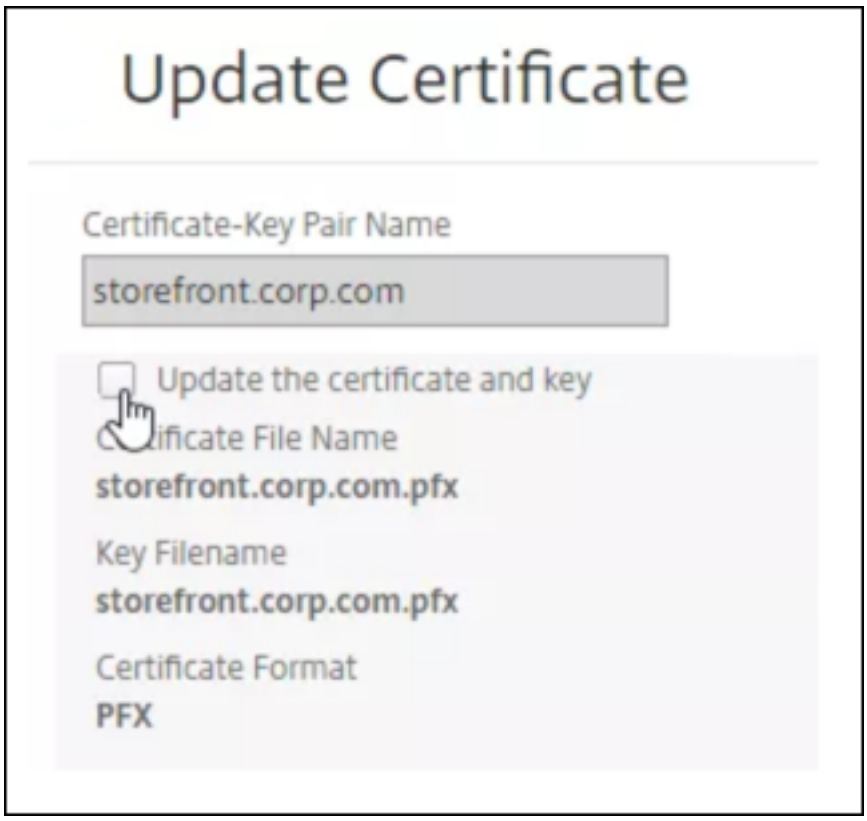
show ssl certkey siteAcertkey



Name: siteAcertkey       Status: Valid
          Version: 3
          Serial Number: 02
          Signature Algorithm: md5WithRSAEncryption
          Issuer: /C=US/ST=CA/L=Santa Clara/O=siteA/OU=Tech
          Validity
               Not Before: Nov 11 14:58:18 2001 GMT
```

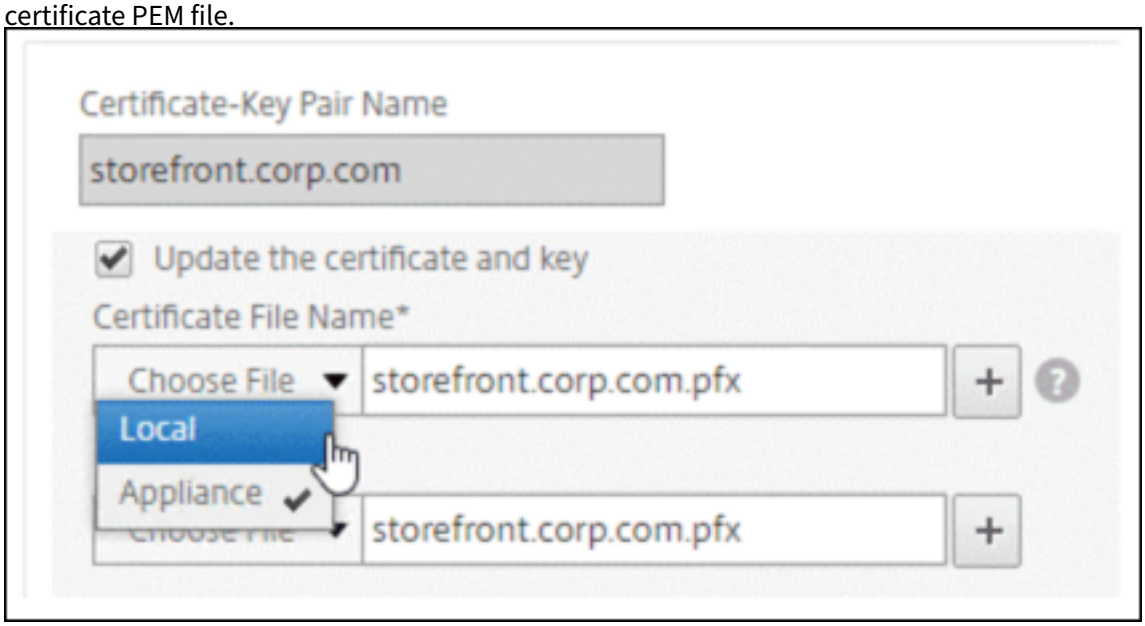
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
                Not After: Aug 7 14:58:18 2004 GMT
            Subject: /C=US/ST-CA/L=San Jose/O=CA/OU=Security
            Public Key Algorithm: rsaEncryption
            Public Key size: 2048
Done
```



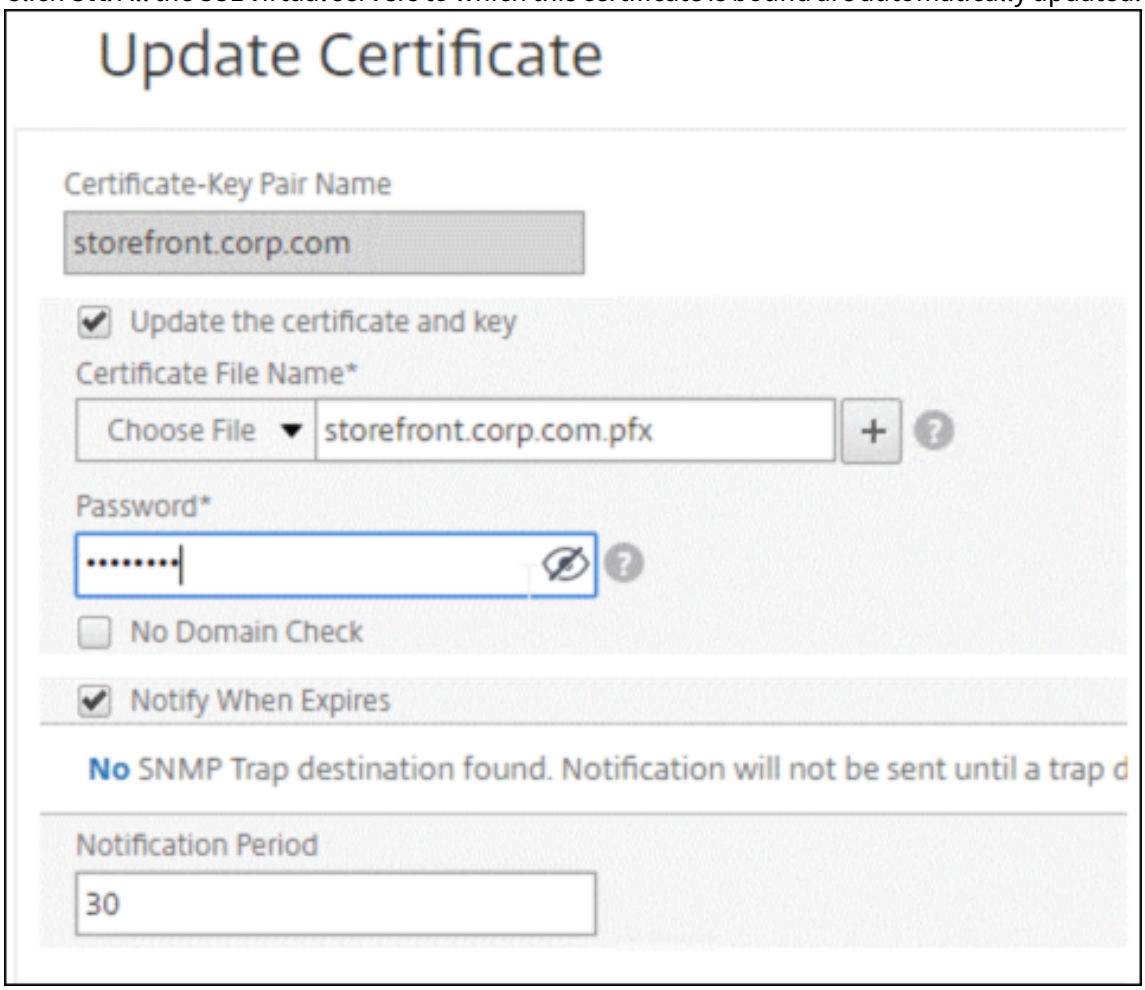
Update an existing certificate-key pair by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Certificates** > **Server Certificates**.
2. Select the certificate that you want to update, and click **Update**.



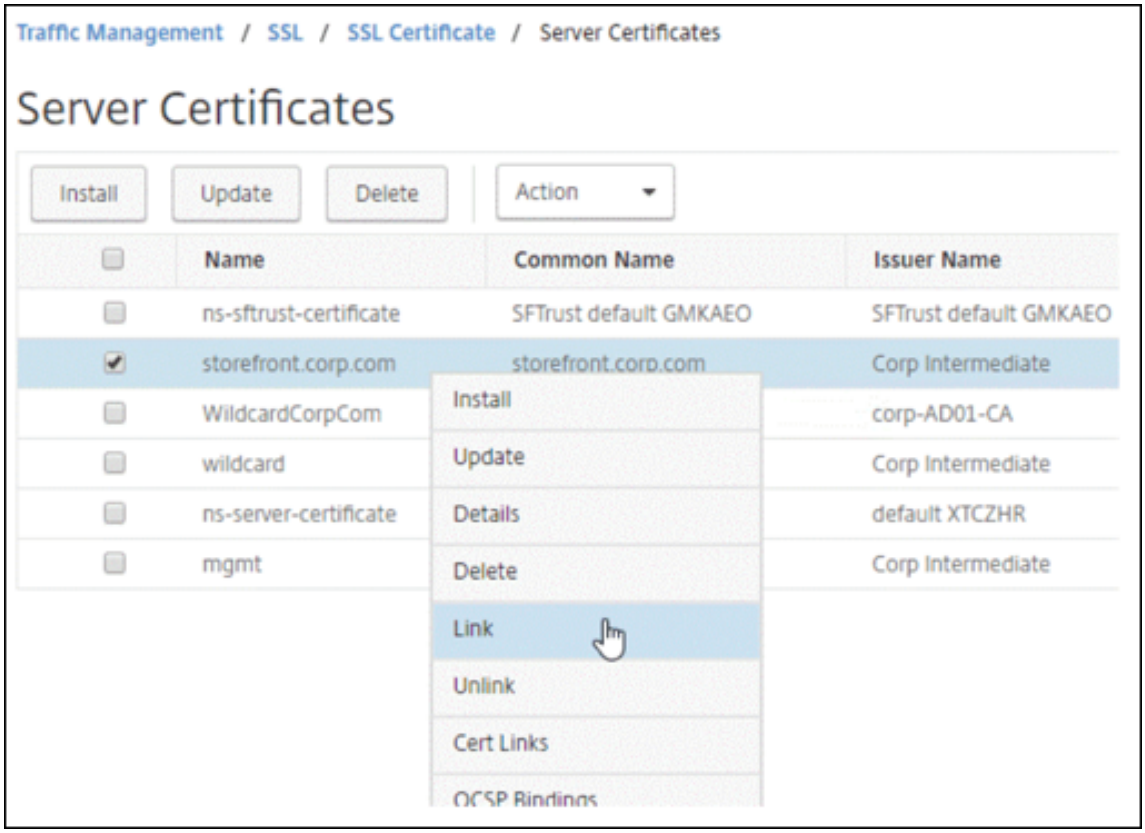
3. Select **Update the certificate and key**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



4. In **Certificate File Name**, click **Choose File** > **Local**, and browse to the updated .pfx file or certificate PEM file.

- If you upload a .pfx file, you are prompted to specify the .pfx file password.
- If you upload a certificate pem file, you must also upload a certificate key file. If the key is encrypted, you must specify the encryption password.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

5. If the common name of the new certificate does not match the old certificate, then select **No Domain Check**.
6. Click **OK**. All the SSL virtual servers to which this certificate is bound are automatically updated.

7. After replacing the certificate, you might have to update the certificate link to a new intermediate certificate. For more information about updating an intermediate certificate without breaking the links, see Update an intermediate certificate without breaking the links.
    - Right-click the updated certificate, and click **Cert Links**, to see if it is linked to an intermediate certificate.
    - If the certificate is not linked, then right-click the updated certificate, and click **Link** to link it to an intermediate certificate. If you don't see an option to link, then you must first have to install a new intermediate certificate on the appliance under the **CA Certificates** node.

Update an existing CA certificate

The steps to update an existing CA certificate are the same as updating an existing server certificate. The only difference is that you do not need a key in the case of CA certificates.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Disable domain checks

When an SSL certificate is replaced on the appliance, the domain name mentioned on the new certificate must match the domain name of the certificate being replaced. For example, if you have a certificate issued to abc.com, and you are updating it with a certificate issued to def.com, the certificate update fails.

However, if you want the server that has been hosting a particular domain to host a new domain, disable the domain check before updating its certificate.

Disable the domain check for a certificate by using the CLI

At the command prompt, type the following commands to disable the domain check and verify the configuration:

```
update ssl certKey <certkeyName> -noDomainCheck

show ssl certKey <certkeyName>
```

Example:

```
update ssl certKey sv -noDomainCheck

Done

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
show ssl certkey sv

Name: sv
Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
Format: PEM
Status: Valid,   Days to expiration:9349
Certificate Expiry Monitor: DISABLED
Done
```

Disable the domain check for a certificate by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates**, select a certificate, and click **Update**.
2. Select **No Domain Check**.

Replace the default certificate of an ADC appliance with a trusted CA certificate that matches the host name of the appliance

The following procedure assumes that the default certificate (`ns-server-certificate`) is bound to the internal services.

1. Navigate to **Traffic Management > SSL > SSL Certificates > Create Certificate Request**.
2. In common name, type `test.citrixadc.com`.
3. Submit the CSR to a trusted certificate authority.
4. After receiving the certificate from the trusted CA, copy the file to the `/nsconfig/ssl` directory.
5. Navigate to **Traffic Management > SSL > Certificates > Server Certificates**.
6. Select the default server certificate (`ns-server-certificate`) and click **Update**.
7. In the **Update Certificate** dialog box, in **Certificate File Name**, browse to the certificate received from the CA after signing.
8. In the **Key File Name** field, specify the default private key file name (`ns-server.key`).
9. Select **No Domain Check**.
10. Click **OK**.

Enable the expiry monitor

An SSL certificate is valid for a specific period. A typical deployment includes multiple virtual servers that process SSL transactions, and the certificates bound to them can expire at different times. An expiry monitor configured on the appliance creates entries in the appliance's syslog and ns audit logs when a certificate configured is due to expire.

If you want to create SNMP alerts for certificate expiration, you must configure them separately.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Enable an expiry monitor for a certificate by using the CLI

At the command prompt, type the following commands to enable an expiry monitor for a certificate and verify the configuration:

```
set ssl certKey <certkeyName> [-expiryMonitor ( ENABLED | DISABLED ) [-
    notificationPeriod <positive_integer>]]

show ssl certKey <certkeyName>
```

Example:

```
set ssl certKey sv -expiryMonitor ENABLED  – notificationPeriod 60
Done
```

Enable an expiry monitor for a certificate by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates**, select a certificate, and click **Update**.
2. Select **Notify When Expires**, and optionally specify a notification period.

Update an intermediate certificate without breaking the links

You can now update an intermediate certificate without breaking any existing links. The 'AuthorityKeyIdentifier'extension, in the linked certificate issued by the certificate to be replaced, must not contain an authority certificate serial number ('authorityCertSerialNumber') field. If the 'AuthorityKeyIdentifier'extension contains a serial number field, then the certificate serial numbers of the old and new certificate must be the same. You can update any number of certificates in the link, one at a time, if the preceding condition is met. Previously, the links broke if an intermediate certificate was updated.

For example, there are four certificates: `CertA`, `CertB`, `CertC`, and `CertD`. Certificate `CertA` is the issuer for `CertB`, `CertB` is the issuer for `CertC`, and so on. If you want to replace an intermediate certificate `CertB` with `CertB_new`, without breaking the link, the following condition must be met:

The certificate serial number of `CertB` must match the certificate serial number of `CertB_new` if both of the following conditions are met:

- The `AuthorityKeyIdentifier` extension is present in `CertC`.
- This extension contains a serial number field.

If the common name in a certificate changes, while updating the certificate specify `nodomaincheck`

.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

In the preceding example, to change “www.example.com”in CertD to “*.example.com,”select the ‘No Domain Check”parameter.

Update the certificate by using the CLI

At the command prompt, type:

```
update ssl certKey <certkeyName> -cert <string> [-password] -key <
   string>  [-noDomainCheck]
```

Example:

```
update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /
   nsconfig/ssl/pkey.pem -noDomainCheck
```

Display a certificate chain

A certificate contains the name of the issuing authority and the subject to whom the certificate is issued. To validate a certificate, you must look at the issuer of that certificate and confirm if you trust the issuer. If you do not trust the issuer, you must see who issued the issuer certificate. Go up the chain until you reach the root CA certificate or an issuer that you trust.

As part of the SSL handshake, when a client requests a certificate, the appliance presents a certificate and the chain of issuer certificates present on the appliance. An administrator can view the certificate chain for the certificates present on the appliance and install any missing certificates.

View the certificate chain for the certificates present on the appliance by using the CLI

At the command prompt, type:

```
show ssl certchain <cert_name>
```

Examples

There are 3 certificates: c1, c2, and c3. Certificate c3 is the root CA certificate and signs c2, and c2 signs c1. The following examples illustrate the output of the
`show ssl certchain c1` command in different scenarios.

Scenario 1:

Certificate c2 is linked to c1, and c3 is linked to c2.

Certificate c3 is a root CA certificate.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If you run the following command, the certificate links up to the root CA certificate are displayed.

```
show ssl certchain c1

Certificate chain details of certificate name c1 are:
    1) Certificate name: c2              linked; not a root
       certificate
    2) Certificate name: c3              linked; root certificate
Done
```

Scenario 2:

Certificate c2 is linked to c1.

Certificate c2 is not a root CA certificate.

If you run the following command, the information that certificate c3 is a root CA certificate but is not linked to c2 is displayed.

```
show ssl certchain c1

Certificate chain  details of certificate name c1 are:
    1) Certificate Name: c2              linked; not a root
       certificate
    2) Certificate Name: c3              not linked; root certificate
    Done
```

Scenario 3:

Certificate c1, c2, and c3 are not linked but are present on the appliance.

If you run the following command, information about all the certificates starting with the issuer of certificate c1 is displayed. It is also specified that the certificates are not linked.

```
show ssl certchain c1

Certificate chain details of certificate name c1 are:
    1) Certificate Name: c2              not linked; not a root
       certificate
    2) Certificate Name: c3              not linked; root certificate
    Done
```

Scenario 4:

Certificate c2 is linked to c1.

Certificate c3 is not present on the appliance.

If you run the following command, information about the certificate linked to c1 is displayed. You are prompted to add a certificate with the subject name specified in c2. In this case, the user is asked to add the root CA certificate c3.

```
show ssl certchain c1
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
2
3 Certificate chain details of certificate name c1 are:
4     1) Certificate Name: c2              linked; not a root
       certificate
5     2) Certificate Name: /C=IN/ST=ka/O=netscaler/CN=test
6        Action: Add a certificate with this subject name.
7 Done
```

Scenario 5:

A certificate is not linked to certificate c1 and the issuer certificate of c1 is not present on the appliance.

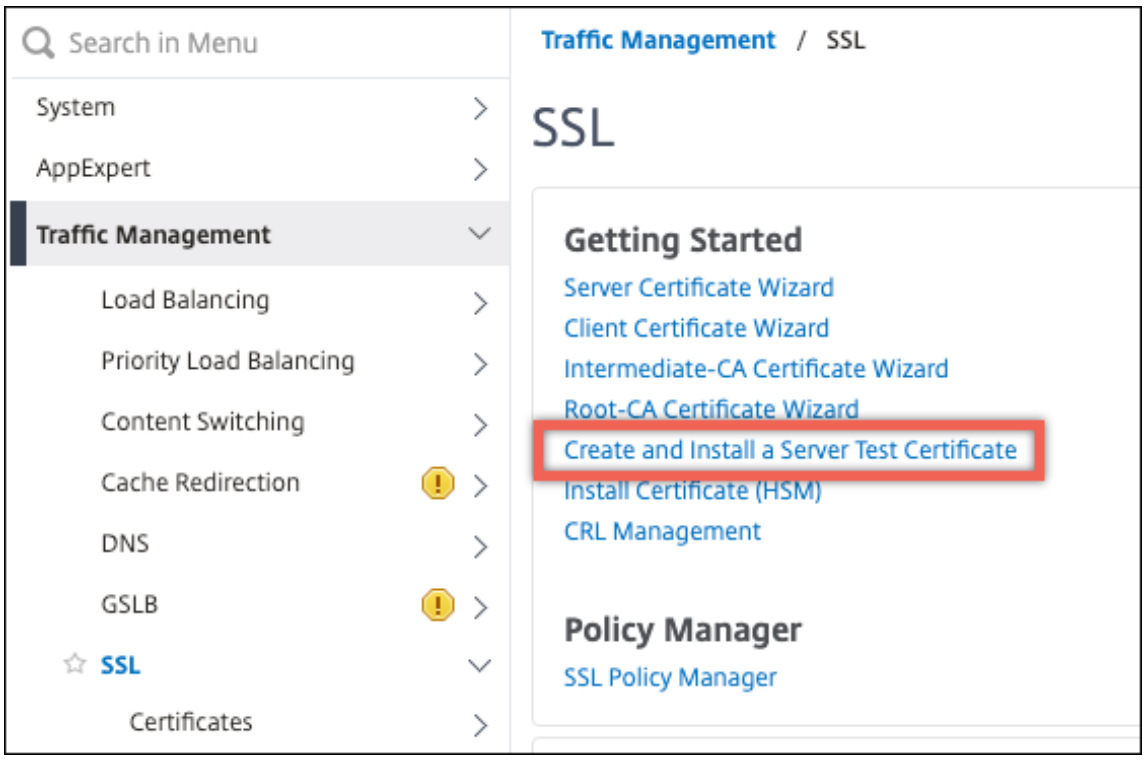
If you run the following command, you are prompted to add a certificate with the subject name in certificate c1.

```
1 sh ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4     1) Certificate Name: /ST=KA/C=IN
5        Action: Add a certificate with this subject name.
```

Generate a server test certificate

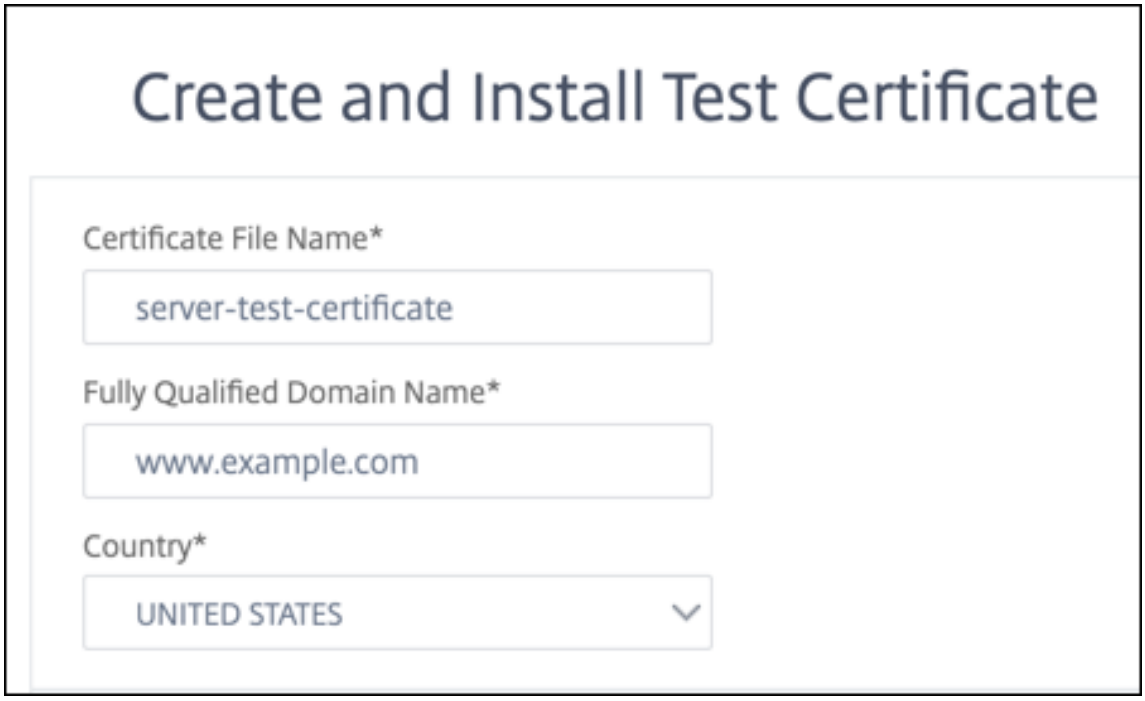
September 14, 2021

The Citrix ADC appliance allows you to create a test certificate for server authentication by using a GUI wizard in the configuration utility. A server certificate is used to authenticate and identify a server in an SSL handshake. Typically, a trusted CA issues a server certificate. The server sends the certificate to a client who uses it to authenticate the server.



For issuing a server test certificate, the appliance operates as a certificate authority. This certificate can be bound to an SSL virtual server for authentication in an SSL handshake with a client. This certificate is for testing purposes only. Do not use in a production environment.

You can install the server test certificate on any virtual server that uses the SSL or the SSL_TCP protocol.



Generate a server test certificate by using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **SSL Certificates group**, select **Create and Install a Server Test Certificate**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. Enter details for the parameters and click **Create**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Import and convert SSL files

September 14, 2021

You can now import SSL resources, such as certificates, private keys, CRLs, and DH keys, from remote hosts even if FTP access to these hosts is not available. This feature is especially helpful in environments where shell access to the remote host is restricted. Default folders are created in /nsconfig/ssl as follows:

- For certificate files: /nsconfig/ssl/certfile
- For private keys: the /nsconfig/ssl/keyfile
- For CRLs: /var/netscaler/ssl/crlfile
- For DH keys: /nsconfig/ssl/dhfile

Imports from both HTTP and HTTPS servers are supported. However, the import fails if the file is on an HTTPS server that requires client certificate authentication for access.

> **Note:**
>
> The import command is not stored in the configuration (ns.conf) file, because reimporting the file after a restart might cause an error.

Import a certificate file

You can use the CLI and GUI to import a file (resource) from a remote host.

Import a certificate file from a remote host by using the CLI

At the command prompt, type:

```
import ssl certFile [<name>] [<src>]
```

Example:

```
import ssl certfile my-certfile http://www.example.com/file_1
```

```
show ssl certfile
     Name : my-certfile
     URL : http://www.example.com/file_1
```

To remove a certificate file, use the `rm ssl certFile` command, which accepts only the 'name' argument.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Import a key file from a remote host by using the CLI

At the command prompt, type:

```
import ssl keyFile [<name>] [<src>]
```

Example:

```
import ssl keyfile my-keyfile http://www.example.com/key_file
```

```
show ssl keyfile
     Name : my-keyfile
     URL : http://www.example.com/key_file
```

To remove a key file, use the `rm ssl keyFile` command, which accepts only the 'name'argument.

Import a CRL file from a remote host by using the CLI

At the command prompt, type:

```
import ssl crlFile [<name>] [<src>]
```

To remove a CRL file, use the `rm ssl crlFile` command, which accepts only the <name> argument.

Example:

```
import ssl crlfile my-crlfile http://www.example.com/crl_file

show ssl crlfile

    Name : my-crlfile
    URL : http://www.example.com/crl_file
```

Import a DH file from a remote host by using the CLI

At the command prompt, type:

```
import ssl dhFile [<name>] [<src>]
```

Example:

```
import ssl dhfile my-dhfile http://www.example.com/dh_file
show ssl dhfile
     Name : my-dhfile
     URL : http://www.example.com/dh_file
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To remove a DH file, use the `rm ssl dhFile` command, which accepts only the <name> argument.

Import an SSL resource by using the GUI

Navigate to **Traffic Management > SSL > Imports**, and then select the appropriate tab.

Import PKCS#8 and PKCS#12 certificates

If you want to use certificates and keys that you already have on other secure servers or applications in your network, you can export them, and then import them to the Citrix ADC appliance. You might have to convert exported certificates and keys before you can import them to the Citrix ADC appliance.

For the details of how to export certificates from secure servers or applications in your network, see the documentation of the server or application from which you want to export.

> **Note:**
>
> For installation on the Citrix ADC appliance, key and certificate names cannot contain spaces or special characters other than those characters supported by the UNIX file system. Follow the appropriate naming convention when you save the exported key and certificate.

A certificate and private key pair is commonly sent in the PKCS#12 format. The appliance supports PEM and DER formats for certificates and keys. To convert PKCS#12 to PEM or DER, or PEM or DER to PKCS#12, see the "Convert SSL certificates for import or export"section later in this page.

The Citrix ADC appliance does not support PEM keys in PKCS#8 format. However, you can convert these keys to a supported format by using the OpenSSL interface, which you can access from the CLI or the configuration utility. Before you convert the key, you need to verify that the private key is in PKCS#8 format. Keys in PKCS#8 format typically start with the following text:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----

leuSSZQZKgrgUQ==

-----END ENCRYPTED PRIVATE KEY-----
```

Open the OpenSSL interface from the CLI

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. Log on to the appliance by using the administrator credentials.
3. At the command prompt, type shell.
4. At the shell prompt type `openssl`.

Open the OpenSSL interface from the GUI

Navigate to **Traffic Management > SSL** and, in the Tools group, select **OpenSSL interface**.

Convert a non-supported PKCS#8 key format to an encrypted supported key format by using the OpenSSL interface

At the OpenSSL prompt, type one of the following commands, depending on whether the non-supported key format is of type RSA or ECDSA:

```
OpenSSL>rsa- in <PKCS#8 Key Filename> -des3 -out <encrypted Key
   Filename>

OpenSSL>ec -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename
   >
```

Parameters for converting an unsupported key format to a supported key format

- **PKCS#8 Key Filename:** The input file name of the incompatible PKCS#8 private key.
- **encrypted Key Filename:** The output file name of the compatible encrypted private key in PEM format.
- **unencrypted Key Filename:** The output file name of the compatible unencrypted private key in PEM format.

Convert SSL certificates for import or export

A Citrix ADC appliance supports the PEM and DER formats for SSL certificates. Other applications, such as client browsers and some external secure servers, require various public key cryptography standard (PKCS) formats. The appliance can convert the PKCS#12 format to PEM or DER format for importing a certificate to the appliance, and can convert PEM or DER to PKCS#12 for exporting a certificate. For more security, conversion of a file for import can include encryption of the private key with the DES or DES3 algorithm.

> **Note:**
>
> If you use the GUI to import a PKCS#12 certificate, and the password contains a dollar sign ($), back quote (‘), or escape () character, the import might fail. If it does, the ERROR: Invalid pass-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

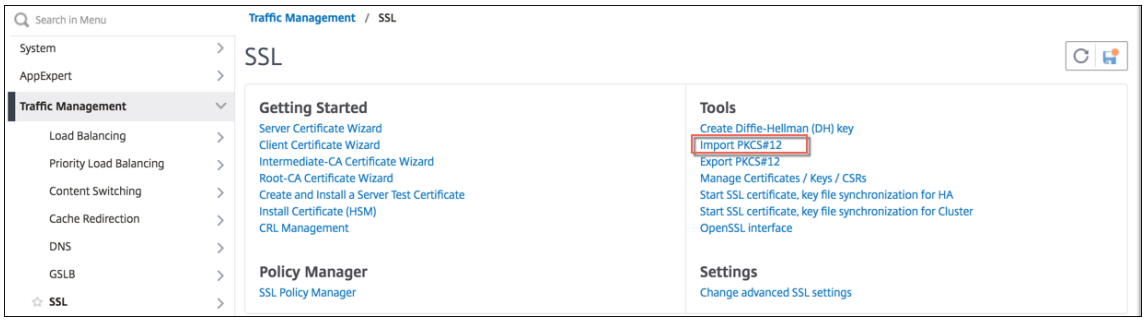
> word message appears. If you must use a special character in the password, be sure to prefix it with an escape character () unless all imports are performed by using the CLI.

Convert the format of a certificate by using the CLI

At the command prompt, type the following command:

```
convert ssl pkcs12 <outfile> [-import [-pkcs12File <inputFilename>] [-
    des | -des3] [-export [-certFile <inputFilename>] [-keyFile <
    inputFilename>]]
```

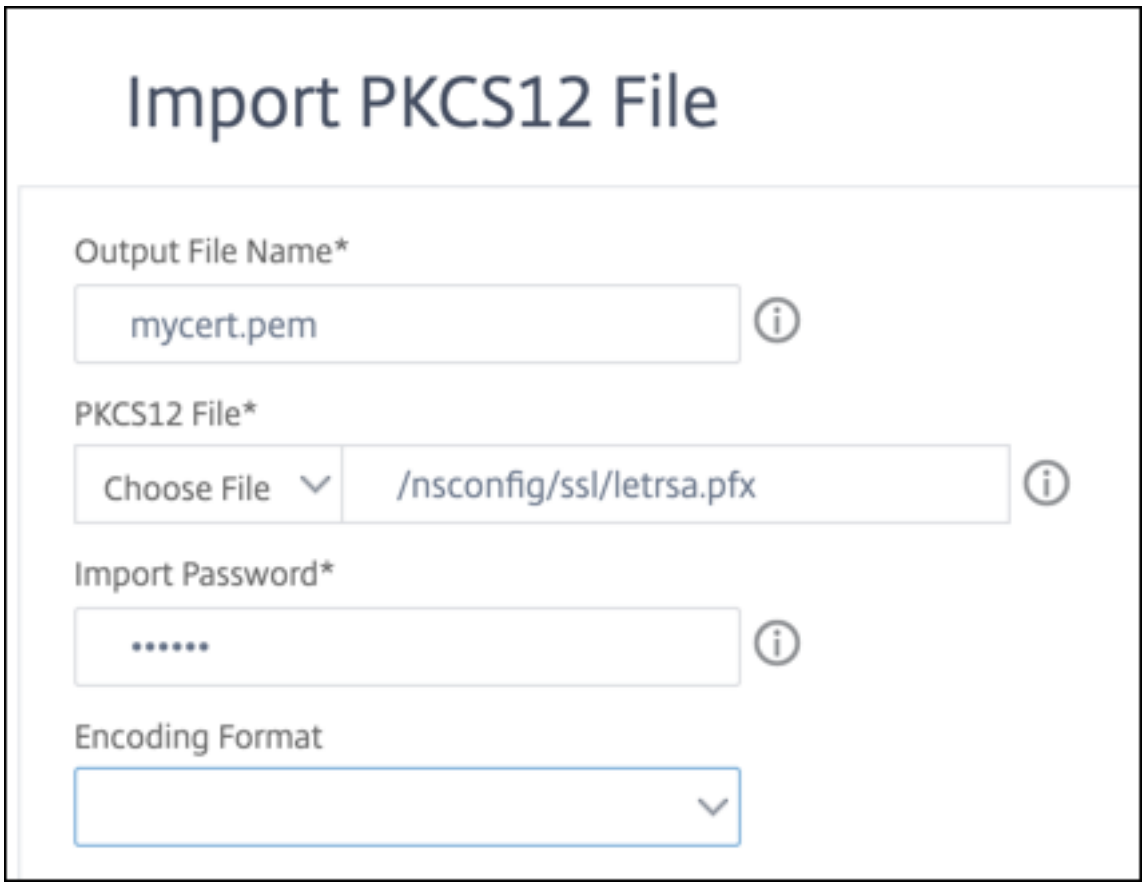
During the operation, you are prompted to enter an import password or an export password. For an encrypted file, you are also prompted to enter a passphrase.



Example:

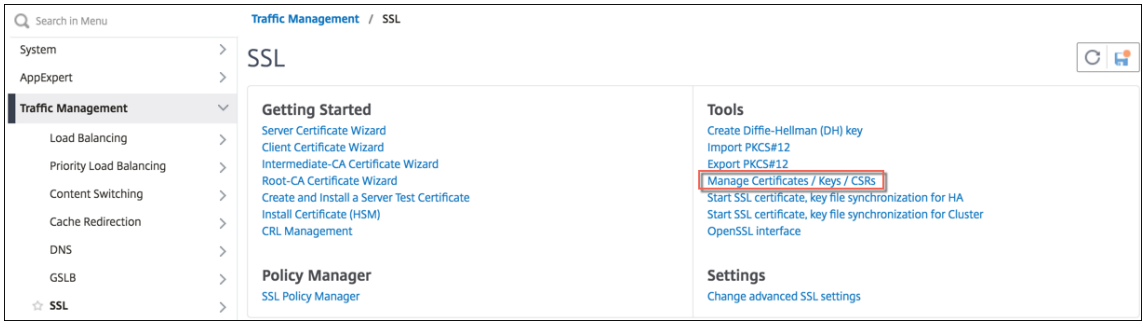
```
convert ssl pkcs12 Cert-Import-1.pem -import -pkcs12File Cert-Import-1.
    pfx -des

convert ssl pkcs12 Cert-Client-1.pfx -export -certFile Cert-Client-1 -
    keyFile Key-Client-1
```

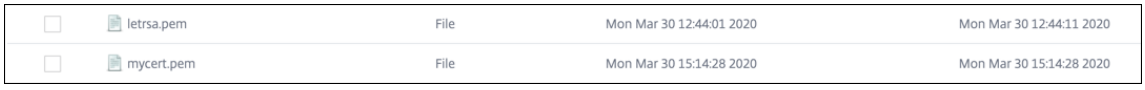


Convert the format of a certificate by using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **Tools** group, select **Import PKCS#12**.

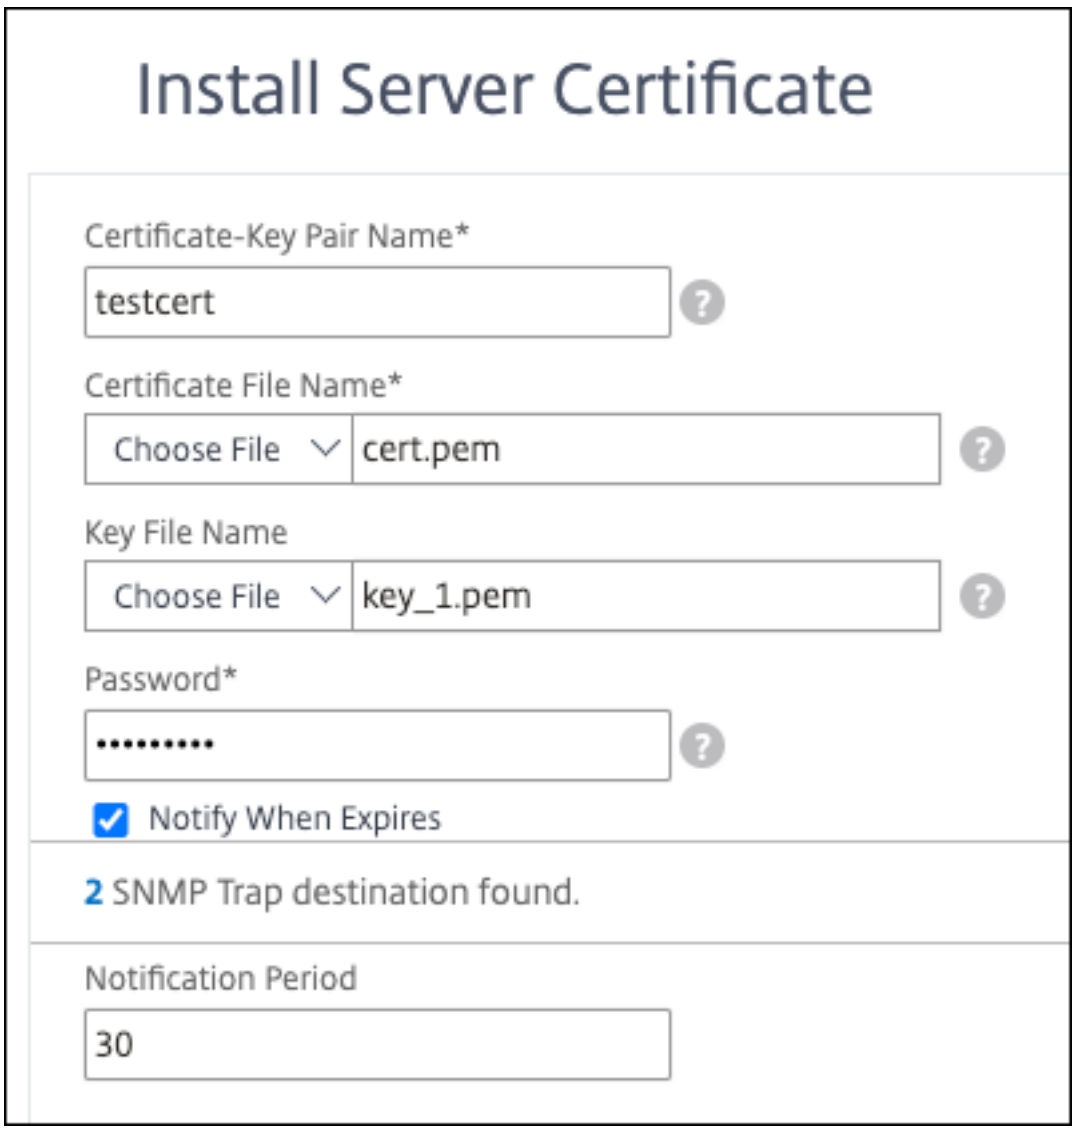


2. Specify the PEM certificate name in the **Output File Name** field.
3. Browse to the location of the PFX certificate on your local computer or the appliance.



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. Click **OK**.
5. Click **Manage Certificates / Keys / CSRs** to view the converted PEM file.



6. You can view the uploaded PFX file and the converted PEM file.

7. Navigate to **SSL** > **Certificates** > **Server Certificates** and click **Install**.
8. Specify a **Certificate-Key Pair Name**.
9. Browse to the location of the PEM file.
10. Specify the password when prompted.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

11. Click **Install**.

12. Bind the certificate-key pair to an SSL virtual server.

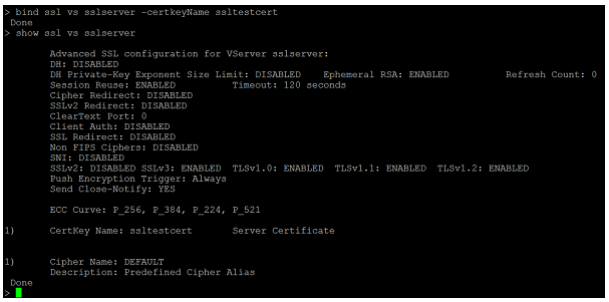
Bind an SSL certificate to a virtual server on the Citrix ADC appliance

May 12, 2023

An SSL certificate is an essential part of SSL encryption and decryption processes. The certificate is used during an SSL handshake to establish the identity of the SSL server, which is the Citrix ADC appliance as it acts as the SSL termination point for the clients.

The certificate used for processing the SSL transactions must be bound to the virtual server (SSL) that

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



receives the SSL data.

To bind an SSL certificate to an SSL virtual server using the command line interface

At the command prompt, type:

```
bind ssl vs <vServerName> -certkeyName <certificate-KeyPairName>
show ssl vs <vServerName>
```

Example:

To bind an SSL certificate to an SSL virtual server using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a virtual server of type SSL and click **Edit**.
3. In the **Load Balancing Virtual Server** page, under the **Certificates** section, click **No Server Certificate**.

4. In the **Server Certificate Binding** page, click **Click to select**.
5. Select the SSL certificate and click **Select**.
6. Click **Bind** to bind the SSL certificate to the virtual server.
7. Click **Done**.

   You have completed binding the SSL certificate to the virtual server.

> **Note**
>
> When you try to bind a certificate-key pair to a virtual server that already has a certificate-key pair bound to it, NetScaler unbinds the old certkey and binds the new one. The following message appears:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> `Warning: Current certificate replaces the previous binding`
>
> Existing connections where the handshake is complete are not affected. The other connections are terminated.

SSL profiles

September 14, 2021

An SSL profile is a collection of settings for SSL entities. It offers ease of configuration and flexibility. Instead of configuring the settings on each entity, you can configure them in a profile and bind the profile to all the entities that the settings apply to.

The SSL profile infrastructure has been enhanced to use the latest ciphers and protocols. Differences between the legacy profile (old profile) and the enhanced SSL profile (new profile) are highlighted.

Differences between the old and the new SSL profile infrastructure

Differences	Old Profile	New Profile
Ciphers and ECC Curves included in the profile	No	Yes
Inserting a cipher or cipher group in the middle of an existing list	Unbind all the ciphers and bind again in the order of the required priority.	Add a cipher and assign it a priority. If a priority is not specified, the cipher is assigned the lowest priority in the list.
Unbinding all the ciphers	`unbind ssl vserver \<name\> ciphername –ALL`	`unbind ssl profile –cipherName FlushAllCiphers` (Release 11.0 build 64.x or later includes the FlushAllCiphers parameter for unbinding all the ciphers or cipher groups from a profile, because ALL is treated like a cipher group.)

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Differences	Old Profile	New Profile
State of SSLv3	n/a	Disabled on the default front-end profile (ns_default_ssl_profile_frontend). Note: Before you enable this profile, SSLv3 is enabled globally. After enabling the profile, SSLv3 is disabled on the front-end default profile.

SSL profile infrastructure

September 14, 2021

Vulnerabilities in SSLv3 and RC4 implementation have emphasized the need to use the latest ciphers and protocols to negotiate the security settings for a network connection. Implementing any changes to the configuration, such as disabling SSLv3 across thousands of SSL end points, is a cumbersome process. Therefore, settings that were part of the SSL end points configuration have been moved to the SSL profiles, along with the default ciphers. To implement changes in the configuration, including cipher support, you need only modify the profile that is bound to the entities.

The default front-end and default back-end SSL profiles contain all the default ciphers and ECC curves, in addition to the settings that were part of the old profiles. Sample outputs for the default profiles are provided in the appendix. The Enable Default Profile operation automatically binds the default front-end profile to all front-end entities, and the default back-end profile to all back-end entities. You can modify a default profile to suit your deployment. You can also create custom profiles and bind them to SSL entities.

The front-end profile contains parameters applicable to a front-end entity. That is, they apply to the entity that receives requests from a client. Typically, this entity is an SSL virtual server or transparent SSL service on the Citrix ADC appliance. The back-end profile contains parameters applicable to a back-end entity. That is, they apply to the entity on the ADC appliance that sends client requests to a back-end server. Typically, this entity is an SSL service on the Citrix ADC appliance. If you try to configure an unsupported parameter, the error `ERROR: Specified parameters are not applicable for this type of SSL profile` appears.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Important:**
>
> - An SSL profile takes precedence over SSL parameters. That is, if you configure SSL parameters using the `set ssl parameter` command, and later bind a profile to an SSL entity, the settings in the profile take precedence.
> - After the upgrade, if you enable the default profiles, you cannot undo the changes. That is, the profiles cannot be disabled. Save the configuration and create a copy of the configuration file (ns.conf) before enabling the profiles. However, if you do not want to use the features in the default profile, you can continue to use the old SSL profiles. For more information about these profiles, see Legacy SSL profile.
> - From release 11.1 51.x, in the GUI and CLI, a confirmation prompt is added when you enable the default profile to prevent enabling it by mistake.

Command:

```
1 set ssl parameter -defaultProfile ENABLED
2     Save your configuration before enabling the Default profile. You
         cannot undo the changes. Are you sure you want to enable the
         Default profile? [Y/N]Y
3 Done
```

By default, some SSL parameters, called *global parameters*, apply to all the SSL end points. However, if a profile is bound to an SSL end point, the global parameters do not apply. The settings specified in the profile apply instead.

Points to note

1. A profile can be bound to multiple virtual servers, but a virtual server can have only one profile bound to it.
2. To delete a profile that is bound to a virtual server, first unbind the profile.
3. A cipher or cipher group can be bound to multiple profiles at different priorities.
4. A profile can have multiple ciphers and cipher groups bound at different priorities.
5. Changes to a cipher group are immediately reflected in all the profiles and in all the virtual servers that one of the profiles is bound to.
6. If a cipher suite is part of a cipher group, edit the cipher group to remove that cipher suite before removing the cipher suite from the profile.
7. If you do not assign a priority to a cipher suite or cipher group attached to a profile, it is assigned the lowest priority within the profile.
8. You can create a custom cipher group (also called a user-defined cipher group) from existing cipher groups and cipher suites. If you create cipher group A and add existing cipher groups X

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

and Y to it, in that order, Y is assigned at a lower priority than X. That is, the group that is added first has a higher priority.

9. If a cipher suite is part of two cipher groups attached to the same profile, the cipher suite is not added as part of the second cipher group. The cipher suite at the higher priority is in effect when traffic is processed.
10. Cipher groups are not expanded in the profile. As a result, the number of lines in the configuration file (ns.conf) is greatly reduced. For example, if two cipher groups containing 15 ciphers each are bound to a thousand SSL virtual servers, expansion adds 30*1000 cipher-related entries in the configuration file. With the new profile, it would have only two entries: one for each cipher group that is bound to a profile.
11. Creating a user defined cipher group from existing ciphers and cipher groups is a copy-paste operation. Any changes in the original group are not reflected in the new group.
12. A user-defined cipher group lists all the profiles that it is a part of.
13. A profile lists all the SSL virtual server, services, and service groups that it is bound to.
14. If the default SSL profile feature is enabled, use the profile to set or change any of the attributes of an SSL entity. For example, virtual server, service, service group, or an internal service.

Save the configuration by using the CLI

At the command prompt, type:

```
save config

shell

root@ns# cd /nsconfig

root@ns# cp ns.conf ns.conf.NS<currentreleasenumber><currentbuildnumber
   >
```

Example:

```
save config
shell
root@ns# cd /nsconfig
root@ns# cp ns.conf ns.conf.NS.11.0.jun.16
```

Enable the default profile

> **Important:**
>
> Save your configuration before you upgrade the software and enable the default profiles.
>
> From release 11.1 build 51.x, in the GUI and CLI, a confirmation prompt appears when you enable

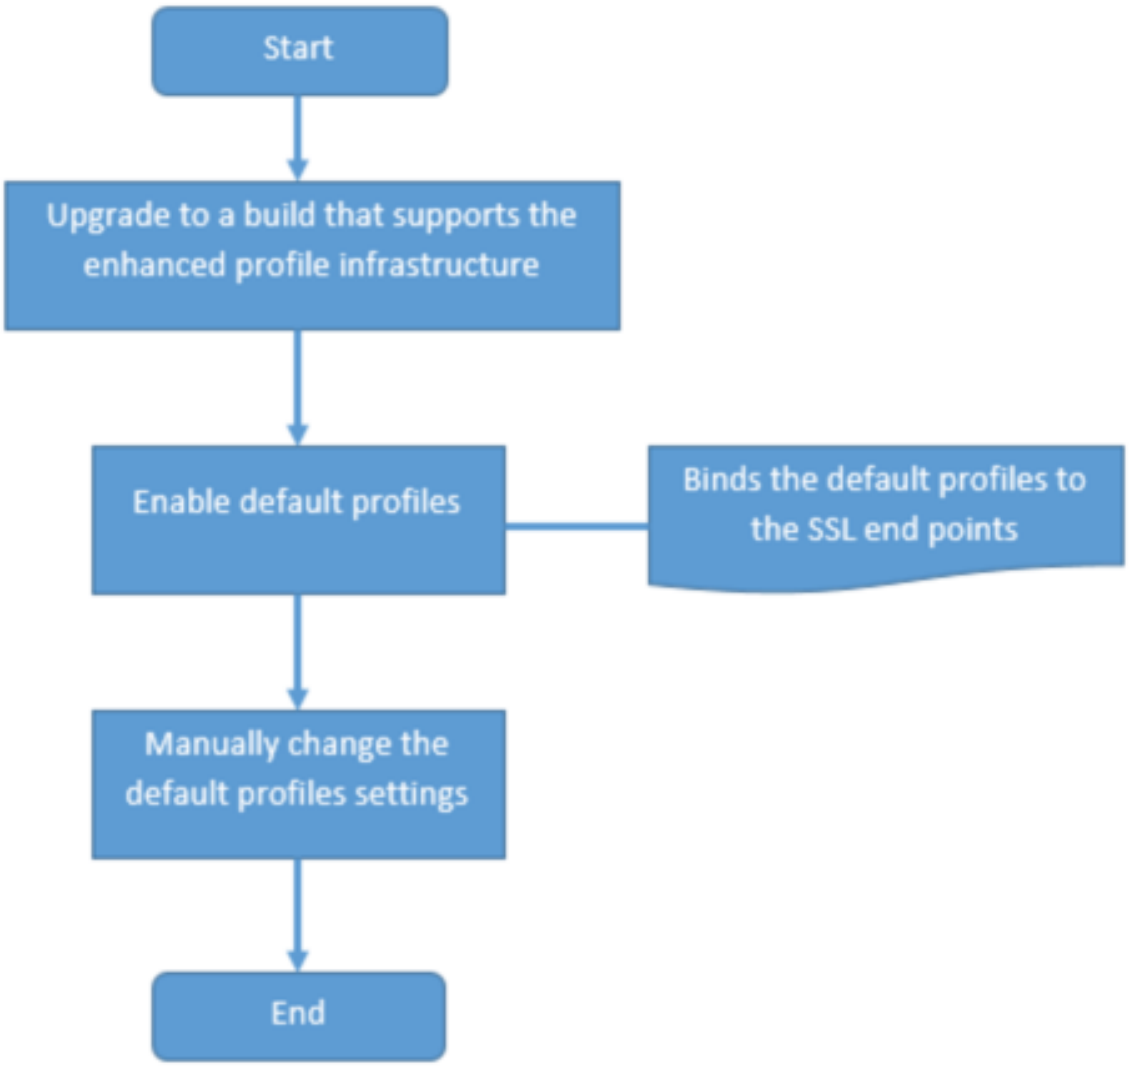
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> the default profile to avoid enabling it by mistake.

Command: The following command enables the default profile and binds this profile to the SSL entities to which a profile is already bound. That is, if a profile (for example P1) is already bound to an SSL entity, the default front-end profile or the default back-end profile replaces P1. The older profile (P1) is not deleted. It is now an enhanced SSL profile and contains the earlier settings, and the ciphers and ECC curves. If you do not want the default profile, you can explicitly bind P1 to the SSL entity.

```
1 set ssl parameter -defaultProfile ENABLED
2     Save your configuration before enabling the Default profile. You
         cannot undo the changes. Are you sure you want to enable the
         Default profile? [Y/N]Y
3 Done
```

Upgrade the software to a build that supports the enhanced profile infrastructure, and then enable the default profiles.



> **Notes:**
>
> - If a legacy profile (P1) is already bound to an SSL entity, and you enable the default profile, the default profile overrides the earlier binding. That is, the default profile is bound to the SSL entities. If you do not want the default profile to be bound, you must bind P1 to the SSL entity again.
> - A single operation (Enable Default Profile or `set ssl parameter -defaultProfile ENABLED`) enables (binds) both the default front-end profile and the default back-end profile.

Use case

After you enable the default profiles, they are bound to all the SSL end points. The default profiles are editable. If your deployment uses most of the default settings and changes only a few parameters, you can edit the default profiles. The changes are immediately reflected across all the end points. You can also create custom SSL profiles with some custom and some default parameters and bind it to the SSL entities.

The following flowchart explains the steps that you must perform:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

1. For information about upgrading the software, see Upgrading the System Software.
2. Enable the default profiles by using the CLI or GUI.

- At the command line, type: `set ssl parameter -defaultProfile ENABLED`
- If you prefer to use the GUI, navigate to **Traffic Management** > **SSL** > **Change advanced SSL settings**, scroll down, and select **Enable Default Profile**.

If a profile was not bound to an end point before the upgrade, a default profile is bound to the SSL end point. If a profile was bound to an end point before the upgrade, the same profile is bound after the upgrade, and default ciphers are added to the profile.

1. (Optional) Manually change any settings in the default profile.

- At the command line, type: `set ssl profile` <name> followed by the parameters to mod-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

ify.

- If you prefer to use the GUI, navigate to **System** > **Profiles**. In **SSL Profiles**, select a profile and click **Edit**.

SSL profile parameters

You can set the following SSL parameters in an SSL profile. You can set some of these parameters in an SSL virtual server. For more information about SSL virtual server parameters, see SSL virtual server parameters.

Support for secure renegotiation at the back end of a Citrix ADC appliance

Note: This parameter is introduced in release 13.0 build 58.x and later. In earlier releases and builds, only non-secure renegotiation was supported on the back end.

The feature is supported on the following platforms:

- VPX
- MPX platforms containing N2 or N3 chips
- Intel Coleto SSL chip based platforms

The feature is not yet supported on the FIPS platform.

Secure renegotiation is denied by default on the back end of an ADC appliance. That is, the denySSLReneg parameter is set to ALL (default).

To allow secure renegotiation on the back end, select from one of the following settings for the denySSLReneg parameter:

- NO
- FRONTEND_CLIENT
- FRONTEND_CLIENTSERVER
- NONSECURE

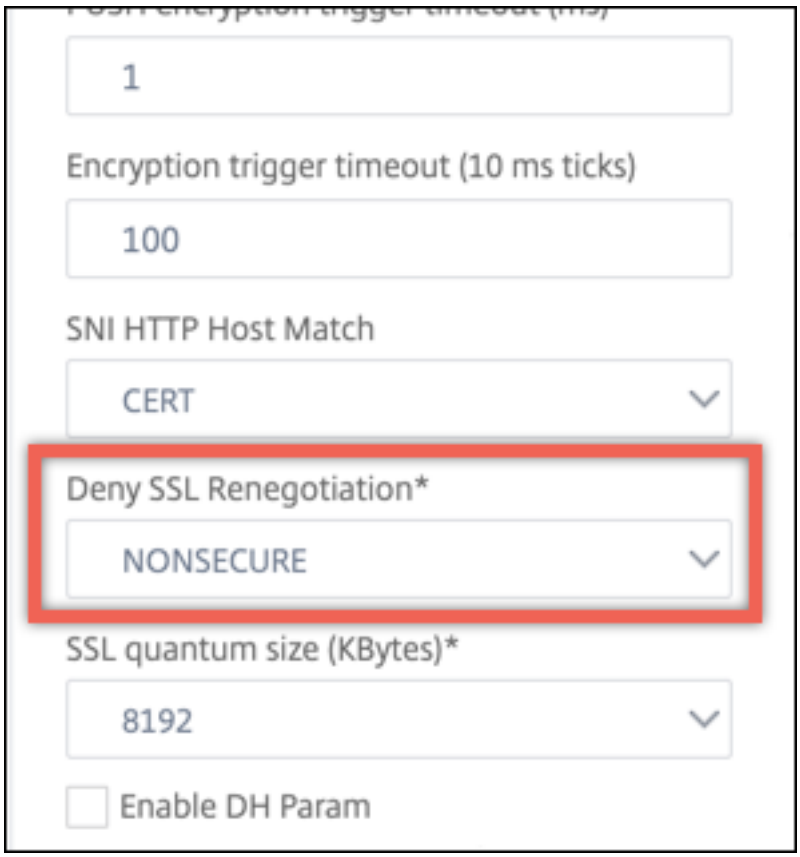
Enable secure renegotiation by using the CLI

At the command prompt, type:

```
set ssl profile <name> -denySSLReneg <denySSLReneg>
```

Example:

```
1 set ssl profile ns_default_ssl_profile_backend -denySSLReneg NONSECURE
2  Done
```



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
3
4  sh ssl profile ns_default_ssl_profile_backend
5  1)  Name: ns_default_ssl_profile_backend    (Back-End)
6      SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2:
           ENABLED  TLSv1.3: DISABLED
7      Server Auth: DISABLED
8      Use only bound CA certificates: DISABLED
9      Strict CA checks:       NO
10     Session Reuse: ENABLED      Timeout: 300 seconds
11     DH: DISABLED
12     Ephemeral RSA: DISABLED
13     Deny SSL Renegotiation      NONSECURE
14     Non FIPS Ciphers: DISABLED
15     Cipher Redirect: DISABLED
16     SSL Redirect: DISABLED
17     Send Close-Notify: YES
18     Strict Sig-Digest Check: DISABLED
19     Push Encryption Trigger: Always
20     PUSH encryption trigger timeout:    1 ms
21     SNI: DISABLED
22     OCSP Stapling: DISABLED
23     Strict Host Header check for SNI enabled SSL sessions:      NO
24     Push flag:  0x0 (Auto)
25     SSL quantum size:       8 kB
26     Encryption trigger timeout  100 mS
27     Encryption trigger packet count:    45
28
29     ECC Curve: P_256, P_384, P_224, P_521
30
31 1)  Cipher Name: DEFAULT_BACKEND        Priority :2
32     Description: Predefined Cipher Alias
33
34 1)  Service Name: s187
35  Done
```

Enable secure renegotiation by using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. Add or edit a profile.
3. Set **Deny SSL Renegotiation** to any value other than ALL.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Host header validation

Note: This parameter is introduced in release 13.0 build 52.x.

With HTTP/1.1, clients had to use multiple connections to process multiple requests. With HTTP/2, clients can reuse connections across domains that are covered by the same certificate. For an SNI enabled session, the ADC appliance must be able to control how the HTTP host header is validated to accommodate this change. In earlier builds, the request was dropped if the parameter was enabled (set to "Yes") and the request did not contain the host header for an SNI enabled session. If the parameter was disabled (set to "No"), the appliance did not perform the validation. A new parameter `SNIHTTPHostMatch` is added to an SSL profile and SSL global parameters to have better control on this validation. This parameter can take three values; CERT, STRICT, and NONE. These values work as follows for SNI enabled sessions only. SNI must be enabled on the SSL virtual server or the profile bound to the virtual server, and the HTTP request must contain the host header.

- CERT - Connection is forwarded if the host header value in the request is covered by the certificate used to establish this SSL session.
- STRICT - Connection is forwarded only if the host header value in the request matches the server name value passed in the Client Hello message of the SSL connection.
- NO - The host header value is not validated.

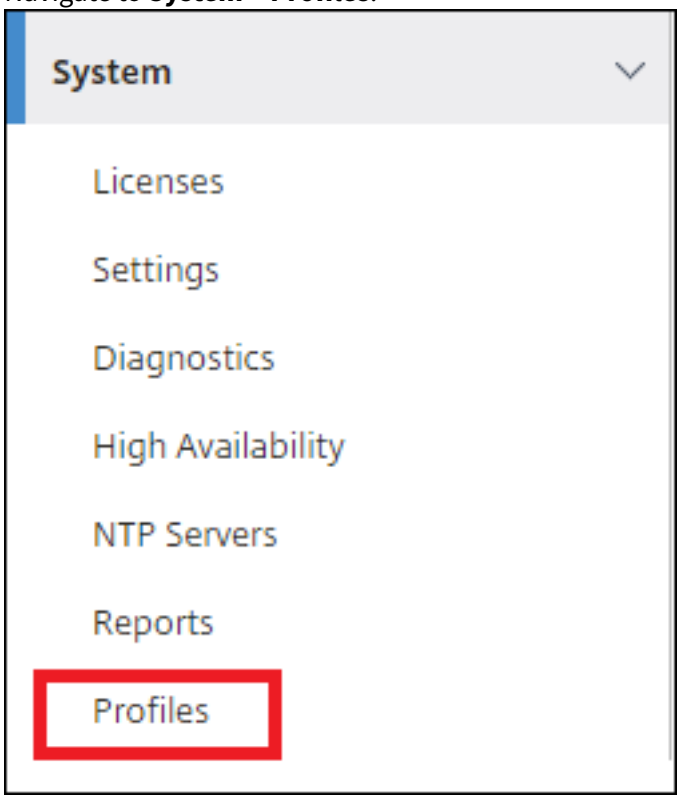
© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Possible values: NO, CERT, STRICT
Default value: CERT

With the introduction of the new parameter SNIHTTPHostMatch there is a change in the behavior of the dropReqWithNoHostHeader parameter. The setting of the dropReqWithNoHostHeader parameter no longer affects how the host header is validated against the SNI certificate.

Set SSL profile parameters by using the CLI

At the command prompt, type:



```
set ssl profile <name> [-ssllogProfile <string>] [-dh ( ENABLED | DISABLED ) -dhFile <string>] [-dhCount <positive_integer>][-dhKeyExpSizeLimit ( ENABLED | DISABLED )] [-eRSA ( ENABLED | DISABLED) [-eRSACount <positive_integer>]] [-sessReuse ( ENABLED | DISABLED )
[-sessTimeout <positive_integer>]] [-cipherRedirect ( ENABLED | DISABLED ) [-cipherURL <URL>]] [-clientAuth ( ENABLED | DISABLED )[-clientCert ( Mandatory | Optional )]] [-sslRedirect ( ENABLED |
DISABLED )] [-redirectPortRewrite ( ENABLED | DISABLED )] [-ssl3 ( ENABLED | DISABLED )] [-tls1 ( ENABLED | DISABLED )] [-tls11 ( ENABLED| DISABLED )] [-tls12 ( ENABLED | DISABLED )] [-tls13 ( ENABLED |DISABLED )] [-SNIEnable ( ENABLED | DISABLED )] [-ocspStapling (ENABLED | DISABLED )] [-serverAuth ( ENABLED | DISABLED )] [-commonName <string>] [-pushEncTrigger <pushEncTrigger>] [-sendCloseNotify ( YES |
NO )] [-clearTextPort <port|*>] [-insertionEncoding ( Unicode | UTF-8)]
 [-denySSLReneg <denySSLReneg>] [-quantumSize <quantumSize>]
[-strictCAChecks ( YES | NO )] [-encryptTriggerPktCount <positive_integer>] [-pushFlag <positive_integer>][-dropReqWithNoHostHeader ( YES | NO )] [-SNIHTTPHostMatch <SNIHTTPHostMatch>] [-pushEncTriggerTimeout <positive_integer>]
[-sslTriggerTimeout <positive_integer>] [-clientAuthUseBoundCAChain ( ENABLED | DISABLED )] [-sslInterception ( ENABLED | DISABLED )][-ssliReneg ( ENABLED | DISABLED )] [-ssliOCSPCheck ( ENABLED | DISABLED )] [-ssliMaxSessPerServer <positive_integer>] [-HSTS ( ENABLED| DISABLED )] [-maxage <positive_integer>] [-IncludeSubdomains ( YES | NO )] [-preload ( YES | NO )] [-sessionTicket ( ENABLED | DISABLED )][-sessionTicketLifeTime <positive_integer>] [-sessionTicketKeyRefresh (ENABLED | DISABLED )] {
 -sessionTicketKeyData  }
  [-sessionKeyLifeTime <positive_integer>] [-prevSessionKeyLifeTime <positive_integer>]
[-cipherName <string> -cipherPriority <positive_integer>][-strictSigDigestCheck ( ENABLED | DISABLED )]
[-skipClientCertPolicyCheck ( ENABLED | DISABLED )] [-zeroRttEarlyData ( ENABLED | DISABLED )] [-tls13SessionTicketsPerAuthContext
<positive_integer>] [-dheKeyExchangeWithPsk ( YES | NO )]
```

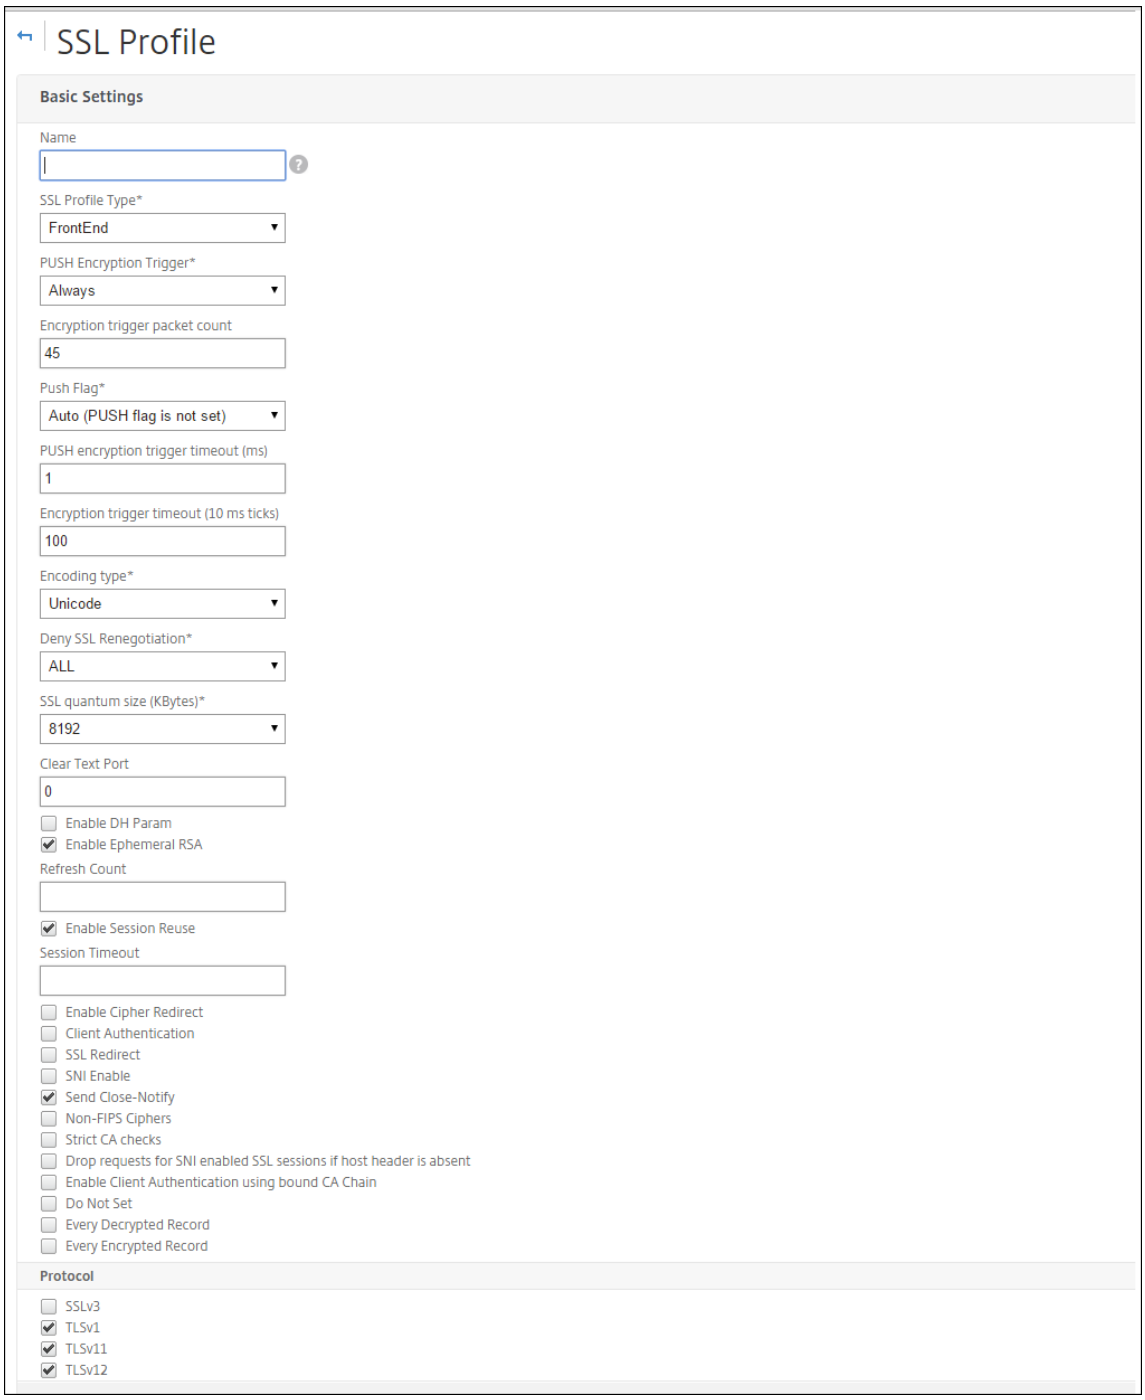
Set SSL profile parameters by using the GUI

To add a profile:

1. Navigate to **System > Profiles**.



2. Select **SSL Profiles**. Click **Add**.

3. Specify values for the different parameters.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. Click **OK**.
5. Click **Done**.

To reuse an existing SSL profile:

1. Navigate to **System > Profiles**.
2. Select an existing profile and click **Add**.
3. Specify a different name, change any parameters, and click **OK**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

4. Click **Done**.

TLS session ticket extension

An SSL handshake is a CPU-intensive operation. If session reuse is enabled, the server/client key exchange operation is skipped for existing clients. They are allowed to resume their sessions. This action improves the response time and increases the number of SSL transactions per second that a server can support. However, the server must store details of each session state, which consumes memory and is difficult to share among multiple servers if requests are load balanced across servers.

Citrix ADC appliances support the SessionTicket TLS extension. Use of this extension indicates that the session details are stored on the client instead of on the server. The client must indicate that it supports this mechanism by including the session ticket TLS extension in the client Hello message. For new clients, this extension is empty. The server sends a new session ticket in the NewSessionTicket handshake message. The session ticket is encrypted by using a key-pair known only to the server. If a server cannot issue a new ticket now, it completes a regular handshake.

This feature is available only in front-end SSL profiles, and only at the front end of communication in which the appliance acts as a server and generates session tickets.

Limitations

- This feature is not supported on a FIPS platform.
- This feature is supported only with TLS versions 1.1 and 1.2.
- SSL session ID persistency is not supported with session tickets.

Enable TLS session ticket extension by using the CLI

At the command prompt, type:

```
set ssl profile <name> -sessionTicket (ENABLED | DISABLED ) [-
    sessionTicketLifeTime <positive_integer>
```

Arguments:

sessionTicket: State of TLS session ticket extension. Use of this extension indicates that the session details are stored on the client instead of on the server, as defined in RFC 5077.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sessionTicketLifeTime: Specify a time, in seconds, after which the session ticket expires and a new SSL handshake must be initiated.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Default value: 300

Minimum value: 0

Maximum value: 172800

Example:

```
1 add ssl profile profile1 -sessionTicket ENABLED -sessionTicketlifeTime
     300
2 Done
```

Enable TLS session ticket extension by using the GUI

1. Navigate to **System** > **Profiles**. Select **SSL Profiles**.
2. Click **Add** and specify a name for the profile.
3. Select **Session ticket**.
4. Optionally, specify **Session Ticket Lifetime (secs)**.

Secure implementation of session tickets

By using TLS session tickets, clients can use abbreviated handshakes for faster reconnection to servers. However, if session tickets aren't encrypted or changed for long periods of time, they can pose a security risk. You can secure session tickets by encrypting them with a symmetric key. To achieve forward secrecy, you can specify a time interval at which the session-ticket key is refreshed.

The appliance generates the session ticket keys by default. However, if multiple appliances in a deployment need to decrypt each other's session tickets, they must all use the same session-ticket key. Therefore, you must set (add or load) the same session-ticket key data manually on all the appliances. Session-ticket key data includes the following information:

- Session ticket name.
- Session AES key used to encrypt or decrypt the ticket.
- Session HMAC key used to compute the digest of the ticket.

You can now configure session ticket key data of length 64 bytes to support 256-bit HMAC keys as recommended in RFC 5077. Key lengths of 48 bytes are also supported for backward compatibility.

> **Note:**
>
> While typing the session-ticket key data manually, ensure that the configuration across all the Citrix ADC appliances in an HA setup or in a cluster setup is the same.

The `sessionTicketKeyLifeTime` parameter specifies how often a session-ticket key is refreshed. You can set the `prevSessionTicketKeyLifeTime` parameter to specify how long the

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

previous session-ticket key will be maintained for decrypting tickets using that key, after a new key is generated. The `prevSessionTicketKeyLifeTime` setting extends the time for which a client can use an abbreviated handshake to reconnect. For example, if `sessionTicketKeyLifeTime` is set to 10 minutes and `prevSessionTicketKeyLifeTime` to 5 minutes, a new key is generated after 10 minutes and used for all new sessions. However, previously connected clients have another 5 minutes for which previously issued tickets are honored for an abbreviated handshake.

Configure SSL session-ticket data by using the CLI

At the command prompt, type:

```
set ssl profile <name> -sessionTicket ENABLED -sessionTicketLifeTime <
    positive_integer> -sessionTicketKeyRefresh ( ENABLED | DISABLED )] -
    sessionTicketKeyLifeTime <positive_integer> [-
    prevSessionTicketKeyLifeTime <positive_integer>]
```

Arguments:

sessionTicket: Use session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the **ENABLED** setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

sessionTicketLifeTime: Lifetime, in seconds, of the session ticket. After this time expires, clients cannot use this ticket to resume their sessions.

Maximum value: 172800. Minimum value: 0. Default: 300.

sessionTicketKeyRefresh: When the time specified by the session-ticket key lifetime parameter expires, regenerate the session-ticket key used to encrypt or decrypt the session tickets. Automatically enabled if sessionTicket is enabled. Disabled if an administrator enters the session-ticket data.

Possible values: ENABLED, DISABLED. Default: ENABLED

sessionKeyLifeTime: Lifetime, in seconds, of a symmetric key used to encrypt the session tickets issued by a Citrix ADC appliance.

Maximum value: 86400. Minimum value: 600. Default: 3000

prevSessionKeyLifeTime: Time, in seconds, for which the previous symmetric key used to encrypt session tickets remains valid for existing clients after the session-ticket key lifetime expires. Within this time, existing clients can resume their sessions by using the previous session ticket key. Session tickets for new clients are encrypted by using the new key.

Maximum value: 172800. Minimum value: 0. Default: 0

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set ssl profile ns_default_ssl_profile_frontend -sessionTicket ENABLED
    -sessionTicketlifeTime 120 -sessionTicketKeyRefresh ENABLED -
    sessionTicketKeyLifeTime 100 -prevSessionTicketKeyLifeTime 60

Done

show ssl profile ns_default_ssl_profile_frontend

     Session Ticket: ENABLED
     Session Ticket Lifetime: 120 (secs)
     Session Key Auto Refresh: ENABLED
     Session Key Lifetime: 100 (secs)
     Previous Session Key Lifetime: 60 (secs)
```

Configure SSL session-ticket data by using the GUI

1. Navigate to **System** > **Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. In the **Basic Settings** section, click the pencil icon and set the following parameters:
   - Session Ticket
   - Session Ticket Lifetime (secs)
   - Session Ticket Key Auto Refresh
   - Session Ticket Key Lifetime (secs)
   - Previous Session Ticket Key Lifetime (secs)
4. Click **OK**.

Type SSL session ticket data manually by using the CLI

At the command prompt, type:

```
set ssl profile <name> -sessionTicket ENABLED

set ssl profile <name> -sessionTicketKeyData

show ssl profile ns_default_ssl_profile_frontend
```

Arguments:

sessionTicket: Use of session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the **ENABLED** setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

sessionTicketKeyData: Contains the session ticket name (0–15 bytes), the session AES key used to encrypt or decrypt the session ticket (16–31 bytes), and the session HMAC key used to compute the digest of the ticket (32–63 bytes). Externally generated by an administrator and added to a Citrix ADC appliance.

Maximum length: 64 bytes

Example:

```
set ssl profile ns_default_ssl_profile_frontend -sessionTicket ENABLED

Done

set ssl profile ns_default_ssl_profile_frontend -sessionTicketKeyData
    111111111111111111111111111111111111111111111111

Done

show ssl profile ns_default_ssl_profile_frontend

    1) Name: ns_default_ssl_profile_frontend (Front-End)
    SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: ENABLED TLSv1.2: ENABLED

```

Type SSL session ticket data manually by using the GUI

1. Navigate to **System > Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. In the **Basic Settings** section, click the pencil icon and set the following parameters:
   - Session Ticket
   - Session Ticket Key Data
   - Confirm Session Ticket Key Data
4. Click **OK**.

Support for Extended Master Secret in SSL handshake on Citrix ADC non-FIPS platforms

Note: This parameter is introduced in release 13.0 build 61.x.

Extended Master Secret (EMS) is an optional extension to the Transport Layer Security (TLS) protocol. A new parameter is added that applies to both front-end and back-end SSL profiles to support EMS on the Citrix ADC appliance. If the parameter is enabled and the peer supports EMS, the ADC appliance uses the EMS calculation. If the peer does not support EMS, then the EMS calculation is not used for the connection even though the parameter is enabled on the appliance. For more information about EMS, see RFC 7627.

Note: EMS is only applicable for handshakes that use TLS protocol version 1.0, 1.1, or 1.2.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Platform support for EMS

- MPX and SDX platforms containing either Cavium N3 chips or Intel Coleto Creek crypto cards. The following platforms ship with Intel Coleto chips:
- MPX 5900
- MPX/SDX 8900
- MPX/SDX 26000
- MPX/SDX 26000-50S
- MPS/SDX 26000-100G
- MPX/SDX 15000-50G

You can also use the "show hardware' command to identify whether your appliance has Coleto (COL) or N3 chips.

- MPX and SDX platforms without crypto cards (software-only).
- Software-only platforms: VPX, CPX, and BLX.

EMS cannot be enabled on the following platforms:

- MPX 9700 FIPS and MPX 14000 FIPS platforms.
- MPX and SDX platforms containing Cavium N2 crypto chips.

If the parameter is enabled, the ADC appliance attempts to use EMS in TLS 1.2, TLS 1.1, and TLS 1.0 connections. The setting does not affect TLS 1.3 or SSLv3 connections.

To allow EMS to be negotiated with the peer, enable the setting on the SSL profile bound to the virtual server (front end) or service (back end).

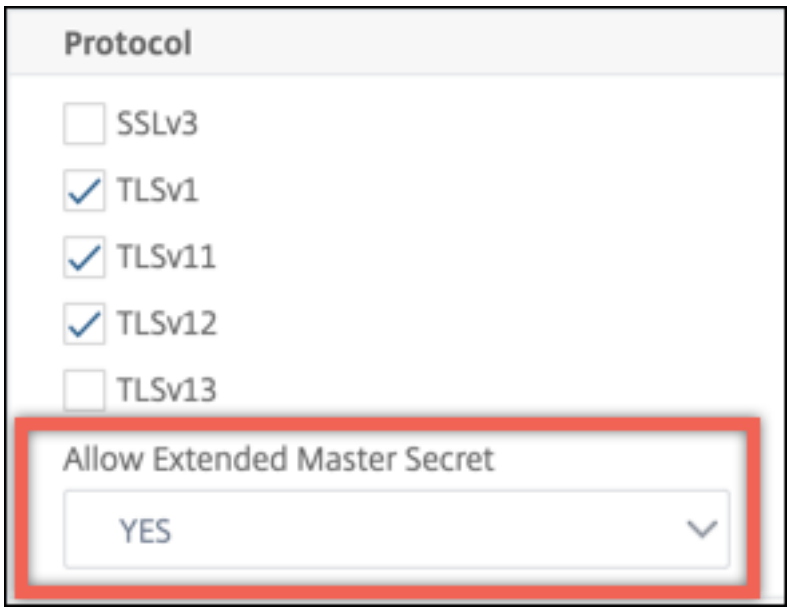
Enable EMS using the CLI

At the command prompt, type:

```
set ssl profile <profile name> [-allowExtendedMasterSecret (YES | NO)
]
```

Examples

```
1 set ssl profile ns_default_ssl_profile_frontend  -
     allowExtendedMasterSecret YES
2
3 set ssl profile ns_default_ssl_profile_backend  -
     allowExtendedMasterSecret YES
```



The following table shows the default value of the `allowExtendedMasterSecret` parameter on different default and user defined profiles.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Profile	Default setting
Default front-end profile	NO
Default front-end secure profile	YES
Default back-end profile	NO
User-defined profile	NO

Enable EMS using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. Add a profile or edit a profile.
3. Set **Allow Extended Master Secret** to YES.

Support for processing of ALPN extension in the client hello message

Note: This feature is supported in release 13.0 build 61.x and later.

A parameter `alpnProtocol` is added to the front-end SSL profiles to negotiate the application protocol in the ALPN extension for the connections handled by the SSL_TCP virtual server. Only the protocol specified in the SSL profile is negotiated, if the same protocol is received in the ALPN extension of the client hello message.

Note: The `alpnProtocol` parameter is supported only on front end SSL profiles and is applicable to the SSL connections handled by SSL_TCP type virtual servers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Set the protocol in the front-end SSL profile using the CLI

At the command prompt, type:

```
set ssl profile ns_default_ssl_profile_frontend -alpnProtocol <
protocol_name>
```

The `alpnProtocol` parameter can take three values. Maximum length: 4096 bytes.

- **NONE:** Application protocol negotiation does not take place. This setting is the default.
- **HTTP1:** HTTP1 can be negotiated as the application protocol.
- **HTTP2:** HTTP2 can be negotiated as the application protocol.

Example:

```
set ssl profile ns_default_ssl_profile_frontend -ALPNProtocol HTTP2
> sh ssl profile ns_default_ssl_profile_frontend
1)  Name: ns_default_ssl_profile_frontend   (Front-End)
    SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2:
       ENABLED  TLSv1.3: DISABLED
    Client Auth: DISABLED
    Use only bound CA certificates: DISABLED
    Strict CA checks:   NO
    Session Reuse: ENABLED  Timeout: 120 seconds
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED    Ephemeral RSA:
       ENABLED  Refresh Count: 0
    Deny SSL Renegotiation  ALL
    Non FIPS Ciphers: DISABLED
    Cipher Redirect: DISABLED
    SSL Redirect: DISABLED
    Send Close-Notify: YES
    Strict Sig-Digest Check: DISABLED
    Zero RTT Early Data: DISABLED
    DHE Key Exchange With PSK: NO
    Tickets Per Authentication Context: 1
    Push Encryption Trigger: Always
    PUSH encryption trigger timeout:    1 ms
    SNI: DISABLED
    OCSP Stapling: DISABLED
    Strict Host Header check for SNI enabled SSL sessions:  NO
    Match HTTP Host header with SNI:    CERT
    Push flag:  0x0 (Auto)
    SSL quantum size:   8 kB
    Encryption trigger timeout  100 mS
    Encryption trigger packet count:    45
    Subject/Issuer Name Insertion Format:   Unicode

    SSL Interception: DISABLED
    SSL Interception OCSP Check: ENABLED
    SSL Interception End to End Renegotiation: ENABLED
    SSL Interception Maximum Reuse Sessions per Server: 10
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
36      Session Ticket: DISABLED
37      HSTS: DISABLED
38      HSTS IncludeSubDomains: NO
39      HSTS Max-Age: 0
40      HSTS Preload: NO
41      Allow Extended Master Secret: NO
42      Send ALPN Protocol: HTTP2
43
44   Done
```

Set the protocol in the front-end SSL profile using the GUI

1. Navigate to **System > Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. In the **ALPN Protocol** list, select **HTTP2**.

Load an old configuration

Enabling the default profiles is not reversible. However, if you decide that your deployment does not require the default profiles, you can load an older configuration that you saved before you enabled the default profiles. The changes are effective after you restart the appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Load an old configuration by using the CLI

At the command prompt, type:

```
shell

root@ns# clear config

root@ns# cd /nsconfig

root@ns# cp ns.conf.NS.11.0.jun.16 ns.conf

root@ns# reboot
```

Secure front-end profile

September 14, 2021

In addition to a default front-end and a default back-end profile, a new default secure front-end profile is available from release 12.1. The settings required for an A+ rating (as of May 2018) from Qualys SSL Labs are preloaded into this profile. Earlier, you had to explicitly set each of the parameters required for an A+ rating on an SSL front-end profile or an SSL virtual server. Now you can bind the ns_default_ssl_profile_secure_frontend profile to your SSL virtual server and the required parameters are automatically set on your SSL virtual server.

> **Note:**
>
> The secure front-end profile is not editable.

When you enable the default profile, the default front-end profile is automatically bound to all the SSL virtual servers. To get an A+ rating, you must explicitly bind the ns_default_ssl_profile_secure_frontend profile and also bind an SHA2/SHA256 server certificate to your SSL virtual server.

Secure front-end profile parameters

The parameters with their default settings are listed here:

```
SSLv3: DISABLED  TLSv1.0: DISABLED  TLSv1.1: DISABLED  TLSv1.2: ENABLED
     TLSv1.3: DISABLED

Deny SSL Renegotiation: NONSECURE

HSTS: ENABLED

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
7  HSTS IncludeSubDomains: YES
8
9  HSTS Max-Age: 15552000
10
11 Cipher Name: SECURE    Priority :1
```

Secure cipher alias

A new secure cipher alias is added and bound to the secure front-end profile. To list the ciphers that are part of this alias, at the command prompt type: show cipher SECURE

```
1  show cipher SECURE
2
3      1) Cipher Name: TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 Priority : 1
4             Description: TLSv1.2 Kx=ECC-DHE  Au=RSA  Enc=AES-GCM(256)
                  Mac=AEAD   HexCode=0xc030
5      2) Cipher Name: TLS1.2-ECDHE-RSA-AES128-GCM-SHA256 Priority : 2
6             Description: TLSv1.2 Kx=ECC-DHE  Au=RSA  Enc=AES-GCM(128)
                  Mac=AEAD   HexCode=0xc02f
7      3) Cipher Name: TLS1.2-ECDHE-ECDSA-AES256-GCM-SHA384
          Priority : 3
8             Description: TLSv1.2 Kx=ECC-DHE  Au=ECDSA Enc=AES-GCM(256)
                  Mac=AEAD   HexCode=0xc02c
9      4) Cipher Name: TLS1.2-ECDHE-ECDSA-AES128-GCM-SHA256
          Priority : 4
10            Description: TLSv1.2 Kx=ECC-DHE  Au=ECDSA Enc=AES-GCM(128)
                  Mac=AEAD   HexCode=0xc02b
11 Done
```

Configuration

Perform the following steps:

1. Add a load balancing virtual server of type SSL.
2. Bind a SHA2/SHA256 certificate.
3. Enable the default profile.
4. Bind the secure front-end profile to the SSL virtual server.

Get an A+ rating for an SSL virtual server by using the CLI

At the command prompt, type:

```
1  add lb vserver <name> <serviceType> <IPAddress> <port>
2  bind ssl vserver <vServerName> -certkeyName <string>
3  set ssl parameter -defaultProfile ENABLED
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set ssl vserver <vServerName> -sslProfile
   ns_default_ssl_profile_secure_frontend
show ssl vserver [<vServerName>]
```

Example:

```
add lb vserver ssl-vsvr SSL 192.0.2.240 443

bind ssl vserver ssl-vsvr -certkeyName letrsa

set ssl parameter -defaultProfile ENABLED

Save your configuration before enabling the Default profile. You cannot
    undo the changes. Are you sure you want to enable the Default
   profile? [Y/N]y

set ssl vserver ssl-vsvr -sslProfile
   ns_default_ssl_profile_secure_frontend
```

```
sh ssl vserver ssl-vsvr

    Advanced SSL configuration for VServer ssl-vsvr:
    Profile Name :ns_default_ssl_profile_secure_frontend
    1) CertKey Name: letrsa     Server Certificate
Done
```

```
sh ssl profile ns_default_ssl_profile_secure_frontend

    1) Name: ns_default_ssl_profile_secure_frontend (Front-End)
    SSLv3: DISABLED  TLSv1.0: DISABLED  TLSv1.1: DISABLED  TLSv1.2:
       ENABLED  TLSv1.3: DISABLED
    Client Auth: DISABLED
    Use only bound CA certificates: DISABLED
    Strict CA checks:                   NO
    Session Reuse: ENABLED   Timeout: 120 seconds
    DH: DISABLED
    DH Private-Key Exponent Size Limit: DISABLED    Ephemeral RSA:
       ENABLED     Refresh Count: 0
    Deny SSL Renegotiation                NONSECURE
    Non FIPS Ciphers: DISABLED
    Cipher Redirect: DISABLED

Get an A+ rating for an SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select an SSL virtual server.
2. In Advanced Settings, click SSL Profile.
3. Select ns_default_ssl_profile_secure_frontend.
4. Click OK.
5. Click Done.

Appendix A: Sample migration of the SSL configuration after upgrade

September 14, 2021

Note: This content has been removed because the SSL migration script for the new default profile is no longer supported.

Appendix B: Default front-end and back-end SSL profile settings

September 14, 2021

A default front-end profile has the following settings:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
sh ssl profile ns_default_ssl_profile_frontend

1)Name: ns_default_ssl_profile_frontend

     Configuration for Front-End SSL profile
     DH: DISABLED
     Ephemeral RSA: ENABLED          Refresh Count: 0
     Session Reuse: ENABLED          Timeout: 120 seconds
     Non FIPS Ciphers: DISABLED
     Cipher Redirect: ENABLED   Redirect URL: http://10.102.28.212/
        redirect.html
     Client Auth: DISABLED
     SSL Redirect: DISABLED
     SNI: DISABLED
     SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2:
        ENABLED
     Push Encryption Trigger: Always
     PUSH encryption trigger timeout:     1 ms
     Send Close-Notify: YES
     Push flag: 0x0 (Auto)
     Deny SSL Renegotiation          NO
     SSL quantum size:          8 kB

      Description: Predefined Cipher Alias

1)    Service Name: s2
2)    Service Name: s1
Done
```

Legacy SSL profile

September 14, 2021

> **Note:**
>
> Citrix recommends using the enhanced profiles instead of legacy profiles. For information about the enhanced profile infrastructure, see SSL profile infrastructure.

Important:

> Bind an SSL profile to an SSL virtual server. Do not bind a DTLS profile to an SSL virtual server. For information about DTLS profiles, see DTLS Profiles.

You can use an SSL profile to specify how a Citrix ADC processes SSL traffic. The profile is a collection of SSL parameter settings for SSL entities, such as virtual servers, services, and service groups, and offers ease of configuration and flexibility. You are not limited to configuring only one set of global parameters. You can create multiple sets (profiles) of global parameters and assign different sets to different SSL entities. SSL profiles are classified into two categories:

- Front end profiles, containing parameters applicable to the front-end entity. That is, they apply to the entity that receives requests from a client.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Back-end profiles, containing parameters applicable to the back-end entity. That is, they apply to the entity that sends client requests to a server.

Unlike a TCP or HTTP profile, an SSL profile is optional. Therefore, there is no default SSL profile. The same profile can be reused across multiples entities. If an entity does not have a profile attached, the values set at the global level apply. For dynamically learned services, current global values apply.

The following table lists the parameters that are part of each profile.

Front end profile	Back-end profile
cipherRedirect, cipherURL	denySSLReneg
clearTextPort*	encryptTriggerPktCount
clientAuth, clientCert	nonFipsCiphers
denySSLReneg	pushEncTrigger
dh, dhFile, dhCount	pushEncTriggerTimeout
dropReqWithNoHostHeader	pushFlag
encryptTriggerPktCount	quantumSize
eRSA, eRSACount	serverAuth
insertionEncoding	commonName
nonFipsCiphers	sessReuse, sessTimeout
pushEncTrigger	SNIEnable
pushEncTriggerTimeout	ssl3
pushFlag	sslTriggerTimeout
quantumSize	strictCAChecks
redirectPortRewrite	tls1
sendCloseNotify	-
sessReuse, sessTimeout	-
SNIEnable	-
ssl3	-
sslRedirect	-
sslTriggerTimeout	-
strictCAChecks	-
tls1, tls11, tls12	-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

* The clearTextPort parameter applies only to an SSL virtual server.

An error message appears if you try to set a parameter that is not part of the profile. For example, if you try to set the clientAuth parameter in a back-end profile.

Some SSL parameters, such as CRL memory size, OCSP cache size, UndefAction Control, and UndefAction Data, are not part of any of the preceding profiles, because these parameters are independent of entities.

An SSL profile supports the following operations:

- Add—Creates an SSL profile on the Citrix ADC. Specify whether the profile is front end or back end. Front end is the default.
- Set—Modifies the settings of an existing profile.
- Unset—Sets the specified parameters to their default values. If you do not specify any parameters, an error message appears. If you unset a profile on an entity, the profile is unbound from the entity.
- Remove—Deletes a profile. A profile that is being used by any entity cannot be deleted. Clearing the configuration deletes all the entities. As a result, the profiles are also deleted.
- Show—Displays all the profiles that are available on the Citrix ADC. If a profile name is specified, the details of that profile are displayed. If an entity is specified, the profiles associated with that entity are displayed.

Create an SSL profile by using the CLI

- To add an SSL profile, type:

```
add ssl profile <name> [-sslProfileType ( BackEnd | FrontEnd )]
```

- To modify an existing profile, type:

```
set ssl profile <name>
```

- To unset an existing profile, type:

```
unset ssl profile <name> [-dh] [-dhFile] [-dhCount] [-eRSA]...
```

- To unset an existing profile from an entity, type:

```
unset ssl vserver <vServerName>  – sslProfile
```

- To remove an existing profile, type:

```
rm ssl profile <name>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- To display an existing profile, type:

```
sh ssl profile <name>
```

Create an SSL profile by using the GUI

Navigate to **System** > **Profiles**, select the SSL Profiles tab, and create an SSL profile.

Enable stricter control on client certificate validation

The Citrix ADC appliance accepts valid Intermediate-CA certificates if a single Root-CA has issued them. That is, if only the Root-CA certificate is bound to the virtual server, and that Root-CA validates any of the intermediate certificates sent with the client certificate, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, the intermediate certificates can be validated by using a CRL or OCSP responder only if that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that one of the CA certificates bound to that virtual server has signed. To do so, you must enable the `ClientAuthUseBoundCAChain` setting in the SSL profile bound to the virtual server. The handshake fails if one of the CA certificates bound to the virtual server has not signed the client certificate.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, the Citrix ADC appliance only accepts clientcert1.

Enable stricter control on client certificate validation by using the CLI

At the command prompt, type: `set ssl profile <name> -ClientAuthUseBoundCAChain Enabled`

Enable stricter control on client certificate validation by using the GUI

1. Navigate to **System** > **Profiles**, select the **SSL Profiles** tab, and create an SSL profile, or select an existing profile.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. Select **Enable Client Authentication using bound CA Chain**.

Certificate revocation lists

September 14, 2021

A certificate issued by a CA typically remains valid until its expiration date. However, in some circumstances, the CA might revoke the issued certificate before the expiration date. For example, when an owner's private key is compromised, a company's or individual's name changes, or the association between the subject and the CA changes.

A Certificate Revocation List (CRL) identifies invalid certificates by serial number and issuer.

Certificate authorities issue CRLs regularly. You can configure the Citrix ADC appliance to use a CRL to block client requests that present invalid certificates.

If you already have a CRL file from a CA, add that to the Citrix ADC appliance. You can configure refresh options. You can also configure the Citrix ADC to sync the CRL file automatically at a specified interval, from either a web location or an LDAP location. The appliance supports CRLs in either the PEM or the DER file format. Be sure to specify the file format of the CRL file being added to the Citrix ADC appliance.

If you have used the ADC as a CA to create certificates that are used in SSL deployments, you can also create a CRL to revoke a particular certificate. This feature can be used, for example, to ensure that self-signed certificates that are created on the Citrix ADC are not used either in a production environment or beyond a particular date.

Note:

By default, CRLs are stored in the /var/netscaler/ssl directory on the Citrix ADC appliance.

Create a CRL on the ADC appliance

Since you can use the ADC appliance to act as a CA and create self-signed certificates, you can also revoke the following certificates:

- Certificates that you have created.
- Certificates whose CA certificate you own.

The appliance must revoke invalid certificates before creating a CRL for those certificates. The appliance stores the serial numbers of revoked certificates in an index file and updates the file each time it revokes a certificate. The index file is automatically created the first time a certificate is revoked.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Revoke a certificate or create a CRL by using the CLI

At the command prompt, type the following command:

```
create ssl crl <CAcertFile> <CAkeyFile> <indexFile> (-revoke <
    input_filename> | -genCRL <output_filename>)
```

Example:

```
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -revoke Invalid-1

create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -genCRL CRL-1
```

Revoke a certificate or create a CRL by using the GUI

1. Navigate to **Traffic Management > SSL** and, in the Getting Started group, select CRL Management.
2. Enter the certificate details and, in the **Choose Operation** list, select **Revoke Certificate**, or **Generate CRL**.

Add an existing CRL to the ADC

Before you configure the CRL on the Citrix ADC appliance, make sure that the CRL file is stored locally on the Citrix ADC appliance. In an HA setup, the CRL file must be present on both ADC appliances, and the directory path to the file must be the same on both appliances.

Add a CRL on the Citrix ADC by using the CLI

At the command prompt, type the following commands to add a CRL on the Citrix ADC and verify the configuration:

```
add ssl crl <crlName> <crlPath> [-inform (DER | PEM)]

show ssl crl [<crlName>]
```

Example:

```
> add ssl crl crl-one /var/netscaler/ssl/CRL-one -inform PEM

Done

> show ssl crl crl-one

            Name: crl-one   Status: Valid,  Days to expiration: 29
            CRL Path: /var/netscaler/ssl/CRL-one
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
9               Format: PEM     CAcert: samplecertkey
10              Refresh: DISABLED
11              Version: 1
12              Signature Algorithm: sha1WithRSAEncryption
13              Issuer:  C=US,ST=California,L=Santa Clara,O=NetScaler Inc.,
                   OU=SSL Acceleration,CN=www.ns.com/emailAddress=
                   support@Citrix ADC appliance.com
14              Last_update:Jun 15 10:53:53 2010 GMT
15              Next_update:Jul 15 10:53:53 2010 GMT
16
17      1)      Serial Number: 00
18              Revocation Date:Jun 15 10:51:16 2010 GMT
19       Done
```

Add a CRL on the Citrix ADC by using the GUI

Navigate to **Traffic Management** > **SSL** > **CRL**, and add a CRL.

Configure CRL refresh parameters

A CRL is generated and published by a Certificate Authority periodically or, sometimes, immediately after a particular certificate is revoked. Citrix recommends that you update CRLs on the Citrix ADC appliance regularly, for protection against clients trying to connect with certificates that are not valid.

The Citrix ADC appliance can refresh CRLs from a web location or an LDAP directory. When you specify refresh parameters and a web location or an LDAP server, the CRL does not have to be present on the local hard disk drive at the time you run the command. The first refresh stores a copy on the local hard disk drive, in the path specified by the CRL File parameter. The default path for storing the CRL is /var/netscaler/ssl.

Note: In release 10.0 and later, the method for refreshing a CRL is not included by default. Specify an HTTP or LDAP method. If you are upgrading from an earlier release to release 10.0 or later, you must add a method and run the command again.

Configure CRL autorefresh by using the CLI

At the command prompt, type the following commands to configure CRL auto refresh and verify the configuration:

```
1 set ssl crl <crlName> [-refresh ( ENABLED | DISABLED )] [-CAcert <
     string>] [-server <ip_addr|ipv6_addr|*> | -url <URL>] [-method (
     HTTP | LDAP )] [-port <port>] [-baseDN <string>] [-scope ( Base |
     One )] [-interval <interval>] [-day <positive_integer>] [-time <HH:
     MM>][-bindDN <string>] {
2  -password  }
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
   [-binary ( YES | NO )]

show ssl crl [<crlName>]
```

Example:

```
    set CRL crl1  -refresh enabled -method ldap -inform DER -CAcert ca1
        -server 10.102.192.192 -port 389 -scope base -baseDN "cn=
       clnt_rsa4_multicert_der,ou=eng,o=ns,c=in" -time 00:01

    set ssl crl crl1 -refresh enabled -method http -cacert ca1 -port 80
        -time 00:10 -url http://10.102.192.192/crl/ca1.crl

    > sh crl

    1)         Name: crl1        Status: Valid,     Days to expiration:
        355
                CRL Path: /var/netscaler/ssl/crl1
                Format: PEM      CAcert: ca1
                Refresh: ENABLED          Method: HTTP
                URL: http://10.102.192.192/crl/ca1.crl
                   Port:80
                Refresh Time: 00:10
                Last Update: Successful, Date:Tue Jul  6 14:38:13 2010
    Done
```

Configure CRL autorefresh using LDAP or HTTP by using the GUI

1. Navigate to **Traffic Management > SSL > CRL**.
2. Open a CRL, and select **Enable CRL Auto Refresh**.

> **Note**
>
> If the new CRL has been refreshed in the external repository before its actual update time as specified by the **Last Update time** field of the CRL, you must do the following:
>
> Immediately refresh the CRL on the Citrix ADC appliance.

To view the last update time, select the CRL, and click **Details**.

Synchronize CRLs

The Citrix ADC appliance uses the most recently distributed CRL to prevent clients with revoked certificates from accessing secure resources.

If CRLs are updated often, the Citrix ADC appliance needs an automated mechanism to fetch the latest CRLs from the repository. You can configure the appliance to update CRLs automatically at a specified

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

refresh interval.

The appliance maintains an internal list of CRLs that need to be updated at regular intervals. At these specified intervals, the appliance scans the list for CRLs that need to be updated. It then connects to the remote LDAP server or HTTP server, retrieves the latest CRLs, and then updates the local CRL list with the new CRLs.

> **Note:**
>
> If the CRL check is set to mandatory when the CA certificate is bound to the virtual server, and the initial CRL refresh fails, the following action is taken for connections:
>
> All client-authentication connections with the same issuer as the CRL are rejected as REVOKED until the CRL is successfully refreshed.

You can specify the interval at which the CRL refresh must be carried out. You can also specify the exact time.

Synchronize CRL autorefresh by using the CLI

At the command prompt, type the following command:

```
set ssl crl <crlName> [-interval <interval>] [-day <integer>] [-time <
    HH:MM>]
```

Example:

```
set ssl crl CRL-1 -refresh ENABLE -interval MONTHLY -days 10 -time
    12:00
```

Synchronize CRL refresh by using the GUI

1. Navigate to **Traffic Management > SSL > CRL**.
2. Open a CRL, select **enable CRL Auto Refresh**, and specify the interval.

Perform client authentication by using a certificate revocation list

If a certificate revocation list (CRL) is present on a Citrix ADC appliance, a CRL check is performed regardless of whether performing the CRL check is set to mandatory or optional.

The success or failure of a handshake depends on a combination of the following factors:

- Rule for CRL check
- Rule for client certificate check

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- State of the CRL configured for the CA certificate

The following table lists the results of the possible combinations for a handshake involving a revoked certificate.

Table 1. Result of a Handshake with a Client Using a Revoked Certificate

Rule for CRL Check	Rule for Client Certificate Check	State of the CRL Configured for the CA certificate	Result of a Handshake with a Revoked Certificate
Optional	Optional	Missing	Success
Optional	Mandatory	Missing	Success
Optional	Mandatory	Present	Failure
Mandatory	Optional	Missing	Success
Mandatory	Mandatory	Missing	Failure
Mandatory	Optional	Present	Success
Mandatory	Mandatory	Present	Failure
Optional/Mandatory	Optional	Expired	Success
Optional/Mandatory	Mandatory	Expired	Failure

> **Note:**
>
> - The CRL check is optional by default. To change from optional to mandatory or conversely, you must first unbind the certificate from the SSL virtual server, and then bind it again after changing the option.
> - In the output of the `sh ssl vserver` command, OCSP check: optional implies that a CRL check is also optional. The CRL check settings are displayed in the output of the `sh ssl vserver` command only if the CRL check is set to mandatory. If the CRL check is set to optional, the CRL check details do not appear.

To configure CRL check by using the CLI

At the command prompt, type the following command:

```
bind ssl vserver <vServerName> -certkeyName <string> [(-CA -crlCheck (
    Mandatory | Optional ))]
sh ssl vserver
```

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
bind ssl vs v1 -certkeyName ca -CA -crlCheck mandatory
> sh ssl vs v1

Advanced SSL configuration for VServer v1:

Monitor certificate status with OCSP

September 14, 2021

Online Certificate Status Protocol (OCSP) is an Internet protocol that is used to determine the status of a client SSL certificate. Citrix ADC appliances support OCSP as defined in RFC 2560. OCSP offers significant advantages over certificate revocation lists (CRLs) in terms of timely information. Up-to-date revocation status of a client certificate is especially useful in transactions involving large sums of money and high-value stock trades. It also uses fewer system and network resources. Citrix ADC implementation of OCSP includes request batching and response caching.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

OCSP implementation

OCSP validation on a Citrix ADC appliance begins when the appliance receives a client certificate during an SSL handshake. To validate the certificate, the appliance creates an OCSP request and forwards it to the OCSP responder. To do so, the appliance uses a locally configured URL. The transaction is in a suspended state until the appliance evaluates the response from the server and determines whether to allow the transaction or reject it. If the response from the server is delayed beyond the configured time and no other responders are configured, the appliance allows the transaction or display an error, depending on whether the OCSP check was set to optional or mandatory, respectively.

The appliance supports batching of OCSP requests and caching of OCSP responses to reduce the load on the OCSP responder and provide faster responses.

OCSP request batching

Each time the appliance receives a client certificate, it sends a request to the OCSP responder. To help avoid overloading the OCSP responder, the appliance can query the status of more than one client certificate in the same request. For this feature to work efficiently, a timeout needs to be defined so that processing of a single certificate is not inordinately delayed while waiting to form a batch.

OCSP response caching

Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder. Upon receiving the revocation status of a client certificate from the OCSP responder, the appliance caches the response locally for a predefined length of time. When a client certificate is received during an SSL handshake, the appliance first checks its local cache for an entry for this certificate. If an entry is found that is still valid (within the cache timeout limit), it is evaluated and the client certificate is accepted or rejected. If a certificate is not found, the appliance sends a request to the OCSP responder and stores the response in its local cache for a configured length of time.

> **Note**: From release 12.1 build 49.x, the cache timeout limit is now increased to a maximum of 43200 minutes (30 days). Earlier the limit was 1440 minutes (one day). The increased limit helps reduce the lookups on the OCSP server and avoid any SSL/TLS connection failures in case the OCSP server is not reachable due to network or other problems.

OCSP responder configuration

Configuring OCSP involves adding an OCSP responder, binding the OCSP responder to a certification authority (CA) certificate, and binding the certificate to an SSL virtual server. If you need to bind a

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

different certificate to an OCSP responder that has already been configured, you need to first unbind the responder and then bind the responder to a different certificate.

Add an OCSP responder by using the CLI

At the command prompt, type the following commands to configure OCSP and verify the configuration:

```
add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED )
    [-cacheTimeout <positive_integer>]] [ -batchingDepth <
    positive_integer>][-batchingDelay <positive_integer>] [-resptimeout
    <positive_integer>] [-responderCert <string> | -trustResponder] [-
    producedAtTimeSkew <positive_integer>][-signingCert <string>][-
    useNonce ( YES | NO )][ -insertClientCert( YES | NO )]
```

```
bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <
    positive_integer>]
```

```
bind ssl vserver <vServerName>@ (-certkeyName <string> ( CA [-ocspCheck
     ( Mandatory | Optional )]))
```

```
show ssl ocspResponder [<name>]
```

Example:

```
add ssl ocspResponder ocsp_responder1 -url "http:// www.myCA.org:80/
    ocsp/" -cache ENABLED -cacheTimeout 30 -batchingDepth 8 -
    batchingDelay 100 -resptimeout 100 -responderCert responder_cert -
    producedAtTimeSkew 300 -signingCert sign_cert  -insertClientCert YES
```

```
bind ssl certKey ca_cert -ocspResponder ocsp_responder1 -priority 1
```

```
bind ssl vserver vs1 -certkeyName ca_cert -CA -ocspCheck Mandatory
```

```
sh ocspResponder ocsp_responder1

    1)Name: ocsp_responder1
    URL: http://www.myCA.org:80/ocsp/, IP: 192.128.22.22
    Caching: Enabled        Timeout: 30 minutes
    Batching: 8 Timeout: 100 mS
    HTTP Request Timeout: 100mS
    Request Signing Certificate: sign_cert
    Response Verification: Full, Certificate: responder_cert
    ProducedAt Time Skew: 300 s
    Nonce Extension: Enabled
     Client Cert Insertion: Enabled
    Done
```

```
show certkey ca_cert
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
2
3     Name: ca_cert     Status: Valid,   Days to expiration:8907
4     Version: 3
5     ...
6
7     1)  VServer name: vs1      CA Certificate
8     1)  OCSP Responder name: ocsp_responder1     Priority: 1
9  Done
```

```
1  sh ssl vs vs1
2
3     Advanced SSL configuration for VServer vs1:
4     DH: DISABLED
5     ...
6
7     1) CertKey Name: ca_cert CA Certificate OCSPCheck: Mandatory
8     1) Cipher Name: DEFAULT
9       Description: Predefined Cipher Alias
10    Done
```

Modify an OCSP responder by using the CLI

You cannot modify the responder name. All other parameters can be changed using the `set ssl ocspResponder` command.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1  set ssl ocspResponder <name> [-url <URL>] [-cache ( ENABLED | DISABLED)
      ] [-cacheTimeout <positive_integer>] [-batchingDepth <
      positive_integer>] [-batchingDelay <positive_integer>] [-resptimeout
       <positive_integer>] [ -responderCert <string> | -trustResponder][-
      producedAtTimeSkew <positive_integer>][-signingCert <string>] [-
      useNonce ( YES | NO )]
2
3  unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]
4
5  bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <
      positive_integer>]
6
7  show ssl ocspResponder [<name>]
```

Configure an OCSP responder by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **OCSP Responder**, and configure an OCSP responder.
2. Navigate to **Traffic Management** > **SSL** > **Certificates**, select a certificate, and in the **Action** list, select **OCSP Bindings**. Bind an OCSP responder.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select **select OCSP Mandatory**.

OCSP stapling

September 14, 2021

The Citrix ADC implementation of CRL and OCSP reports the revocation status of client certificates only. To check the revocation status of a server certificate received during an SSL handshake, a client must send a request to a certificate authority.

For websites with heavy traffic, many clients receive the same server certificate. If each client sent a query for the revocation status of the server certificate, the certificate authority would be inundated with OCSP requests to check the validity of the certificate.

OCSP stapling solution

To avoid unnecessary congestion, the Citrix ADC appliance now supports OCSP stapling. That is, the appliance can now send the revocation status of a server certificate to a client, at the time of the SSL handshake, after validating the certificate status from an OCSP responder. The revocation status of a server certificate is ‘‘stapled’’to the response the appliance sends to the client as part of the SSL handshake. To use the OCSP stapling feature, you must enable it on an SSL virtual server and add an OCSP responder on the appliance.

Note:

- Citrix ADC appliances support OCSP stapling as defined in RFC 6066.
- OCSP stapling is supported only on the front-end of Citrix ADC appliances.

> **Important:**
>
> Citrix ADC support for OCSP stapling is limited to handshakes using TLS protocol version 1.0 or higher.

OCSP response caching of server certificates

During the SSL handshake, when a client requests the revocation status of the server certificate, the appliance first checks its local cache for an entry for this certificate. If a valid entry is found, it is evaluated and the server certificate and its status are presented to the client. If a revocation status entry is

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

not found, the appliance sends a request for the revocation status of the server certificate to the OCSP responder. If it receives a response, it sends the certificate and the revocation status to the client. If the next update field is present in the OCSP response, the response is cached for the configured length of time (value specified in the timeout field.)

> **Note**: From release 12.1 build 49.x, you can clear the cached response, of the server certificate, from the OCSP responder even before the timeout expires. Earlier, it was not possible to discard the cached status in the certificate-key pair until the configured timeout was over.

To clear the cached status by using the CLI, at the command prompt, type:

```
clear ssl certKey <certkey name> -ocspstaplingCache
```

Example:

```
clear ssl certKey s1 -ocspstaplingCache
```

To clear the cached status by using the GUI

1. In the GUI, navigate to **Traffic Management** > **SSL** > **Certificates** > **CA Certificates**.
2. In the details pane, select a certificate.
3. In the **Select Action** list, select **Clear**. When prompted to confirm, click **Yes**.

OCSP stapling configuration

Configuring OCSP stapling involves enabling the feature and configuring OCSP. To configure OCSP, you must add an OCSP responder, bind the OCSP responder to a CA certificate, and bind the certificate to an SSL virtual server.

> **Note:**
>
> OCSP responders with only HTTP based URL are supported.

Enable OCSP stapling by using the CLI

At the command prompt, type:

```
set ssl vserver <name> -ocspstapling [ENABLED | DISABLED]
```

Example:

```
set ssl vserver vip1 -ocspStapling ENABLED
Done

sh ssl vserver vip1

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
6       Advanced SSL configuration for VServer vip1:
7       DH: DISABLED
8       DH Private-Key Exponent Size Limit: DISABLED Ephemeral RSA:
            ENABLED Refresh Count: 0
9       Session Reuse: ENABLED Timeout: 120 seconds
10      Cipher Redirect: DISABLED
11      SSLv2 Redirect: DISABLED
12      ClearText Port: 0
13      Client Auth: DISABLED
14      SSL Redirect: DISABLED
15      Non FIPS Ciphers: DISABLED
16      SNI: ENABLED
17      OCSP Stapling: ENABLED
18      SSLv2: DISABLED SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED
             TLSv1.2: ENABLED
19      Push Encryption Trigger: Always
20      Send Close-Notify: YES
21
22      ECC Curve: P_256, P_384, P_224, P_521
23
24     1) CertKey Name: server_certificate1 Server Certificate
25
26     1) Cipher Name: DEFAULT
27      Description: Default cipher list with encryption strength >= 128
            bit
28  Done
```

Note: If the default (enhanced) profile is enabled, use the `set ssl profile <profile name > -ocspStapling [ENABLED | DISABLED]` command to enable or disable OCSP.

Enable OCSP stapling by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Virtual Server**.
2. Open a virtual server and, in **SSL Parameters**, select **OCSP Stapling**.

OCSP configuration

An OCSP responder is added dynamically or manually to send OCSP stapling requests. An internal responder is dynamically added when you add a server certificate and its issuer certificate based on the OCSP URL in the server certificate. A manual OCSP responder is added from the CLI or GUI. To send an OCSP request for a server certificate, the Citrix ADC appliance selects an OCSP responder based on the priority assigned to it when binding it to an issuer certificate. If a responder fails to send an OCSP stapling request, the responder with the next highest priority is selected for sending the request. For example, if only one responder is manually configured and it fails and a dynamically bound responder exists, it is selected for sending the OCSP request.

If the OCSP URL is other than HTTP, an internal OCSP responder is not created.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> **Note**
>
> A manually added OCSP responder takes precedence over a dynamically added responder.

Difference between a manually created OCSP responder and an internally created OCSP responder

Manually created OCSP responder	Internally (dynamically) created OCSP responder
Created manually and explicitly bound to the issuer certificate with a priority.	Created and bound by default, while adding a server certificate and its issuer certificate (CA certificate). Name starts with ‘‘ns_internal_’’.
Priority between 1 and 127 is reserved for a configured responder.	Priority is automatically assigned from 128 onwards.
URL and batching depth can be changed.	URL and batching depth cannot be changed.
Deleted directly.	Deleted only when you delete the server certificate or the CA certificate.
Can be bound to any CA certificate.	Bound by default to one CA certificate. Cannot be bound to any other CA certificate.
Saved in the configuration (ns.conf).	Add commands are not saved in the configuration. Only set commands are saved.
If you bind three OCSP responders to the same issuer certificate with priorities 1, 2, and 3 respectively, and later unbind priority 2, the other priorities are not affected.	Three OCSP responders are automatically bound to an issuer certificate with priorities 128, 129, and 130 respectively. If you remove the server certificate that was used to create a responder bound with priority 129, then that responder is deleted. Also, the priority for the next responder (priority 130) is automatically changed to 129.

> **Example of request handling**:

1. Add a virtual server (VIP1).
2. Add issuer certificate (CA1) and bind it to VIP1.
3. Add three certificates S1, S2, and S3. Internal responders resp1, resp2, and resp3 respectively are created by default.
4. Bind S3 to VIP1.
5. A request comes to VIP1. Responder resp3 is selected.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

To create an internal OCSP responder dynamically, the appliance needs the following:

- Certificate of the issuer of the server certificate (usually the CA certificate).
- Certificate-key pair of the server certificate. This certificate must contain the OCSP URL provided by the certificate authority. The URL is used as the name of the dynamically added internal responder.

An internal OCSP responder has the same default values as a manually configured responder.

> **Note:**
>
> Caching is disabled by default on an internal responder. Use the `set ssl ocspResponder` command to enable caching.

Configure OCSP by using the CLI

At the command prompt, type the following commands to configure OCSP and verify the configuration:

```
add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>] [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]] [-bundle ( YES | NO )]

add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED ) [-cacheTimeout <positive_integer>]] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>][-signingCert <string>][-useNonce ( YES | NO )][-insertClientCert ( YES | NO )]

bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]

show ssl ocspResponder [<name>]
```

Parameters:

httpMethod:

HTTP method used to send OCSP requests. For requests, less than 255 bytes long, you can configure the HTTP GET method for queries to an OCSP server. If you specify the GET method but the length is greater than 255 bytes, the appliance uses the default method (POST).

Possible values: GET, POST

Default value: POST

ocspUrlResolveTimeout:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Time, in milliseconds, to wait for an OCSP URL resolution. After this time elapses, the responder with the next higher priority is selected. If all the responders fail, an error message appears or the connection is dropped, depending on the settings on the virtual server.

Minimum value: 100

Maximum value: 2000

Example:

```
add ssl certkey root_ca1  – cert root_cacert.pem
add ssl ocspResponder ocsp_responder1 -url "http:// www.myCA.org:80/
    ocsp/" -cache ENABLED -cacheTimeout 30  -resptimeout 100 -
    responderCert responder_cert -producedAtTimeSkew 300 -signingCert
    sign_cert  -insertClientCert YES
bind ssl certKey root_ca1 -ocspResponder ocsp_responder1 -priority 1
sh ocspResponder ocsp_responder1
     1)Name: ocsp_responder1
     URL: http://www.myCA.org:80/ocsp/, IP: 192.128.22.22
     Caching: Enabled        Timeout: 30 minutes
     Batching: 8 Timeout: 100 mS
     HTTP Request Timeout: 100mS
     Request Signing Certificate: sign_cert
     Response Verification: Full, Certificate: responder_cert
     ProducedAt Time Skew: 300 s
     Nonce Extension: Enabled
      Client Cert Insertion: Enabled
     Done

show certkey root_ca1
     Name: root_ca1     Status: Valid,   Days to expiration:8907
     Version: 3
     ...
     1)  OCSP Responder name: ocsp_responder1     Priority: 1
     Done
```

Modify OCSP by using the CLI

You cannot modify the name of an OCSP responder, but you can use the `set ssl ocspResponder` command to change any of the other parameters.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
set ssl ocspResponder <name> [-url <URL>] [-cache ( ENABLED | DISABLED)
    ] [-cacheTimeout <positive_integer>]  [-resptimeout <
    positive_integer>] [ -responderCert <string> | -trustResponder][-
    producedAtTimeSkew <positive_integer>][-signingCert <string>] [-
    useNonce ( YES | NO )]

unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
4
5 bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <
     positive_integer>]
6
7 show ssl ocspResponder [<name>]
```

Configure OCSP by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **OCSP Responder**, and configure an OCSP responder.
2. Navigate to **Traffic Management** > **SSL** > **Certificates**, select a certificate, and in the **Action** list, select **OCSP Bindings**. **Bind an OCSP responder**.
3. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select **OCSP Mandatory**.

> **Note:**
>
> The insert client certificate parameter in the `add ssl ocspResponder` and the `set ssl ocspResponder` commands is no longer valid. That is, the parameter is ignored during configuration.

Ciphers available on the Citrix ADC appliances

January 4, 2024

Your Citrix ADC appliance ships with a predefined set of cipher groups. To use ciphers that are not part of the DEFAULT cipher group, you have to explicitly bind them to an SSL virtual server. You can also create a user-defined cipher group to bind to the SSL virtual server. For more information about creating a user-defined cipher group, see Configure user-defined cipher groups on the ADC appliance.

> **Notes**
>
> RC4 cipher is not included in the default cipher group on the Citrix ADC appliance. However, it is supported in the software on the N3-based appliances. RC4 encryption, including the handshake, is done in software.
>
> Citrix recommends that you do not use this cipher because it is considered insecure and deprecated by RFC 7465.
>
> Use the 'show hardware'command to identify whether your appliance has N3 chips.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

		Not supported	Not supported	12.0–56.x	Not supported

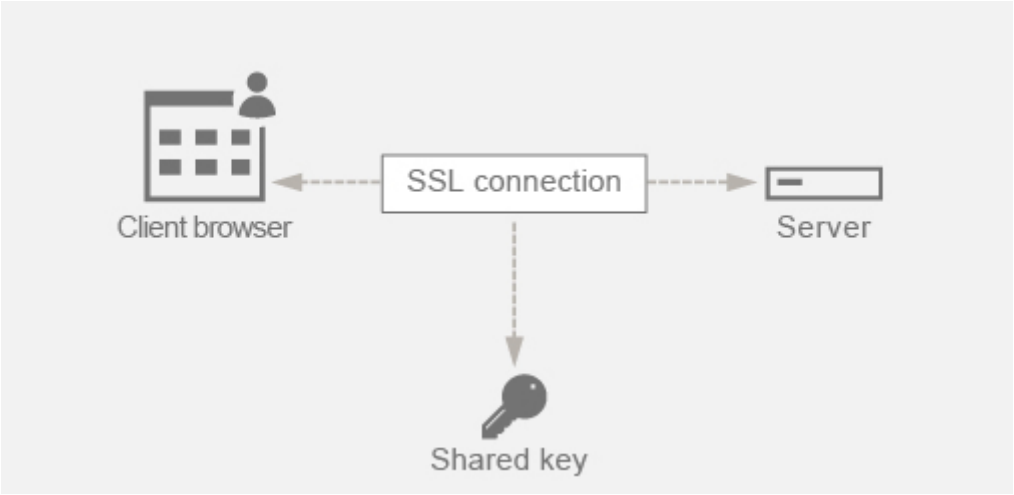
For the detailed list of ECDSA ciphers supported, see ECDSA Cipher Suites support.

> Note
>
> - TLS-Fallback_SCSV cipher suite is supported on all appliances from release 10.5 build 57.x.
> - HTTP Strict Transport Security (HSTS) support is policy-based.
> - All SHA-2 signed-certificates (SHA256, SHA384, SHA512) are supported on the front end of all appliances. In release 11.1 build 54.x and later, these certificates are also supported on the back-end of all appliances. In release 11.0 and earlier, only SHA256 signed-certificates are supported on the back end of all appliances.
> - In release 11.1 build 52.x and earlier, the following ciphers are supported only on the front end of the MPX 9700 and MPX/SDX 14000 FIPS appliances:
>   - TLS1.2-ECDHE-RSA-AES-256-SHA384
>   - TLS1.2-ECDHE-RSA-AES256-GCM-SHA384. From release 11.1 build 53.x, and in release 12.0, these ciphers are also supported on the back end.
> - All ChaCha20-Poly1035 ciphers use a TLS pseudo random function (PSF) with the SHA-256 hash function.

Perfect Forward Secrecy (PFS)



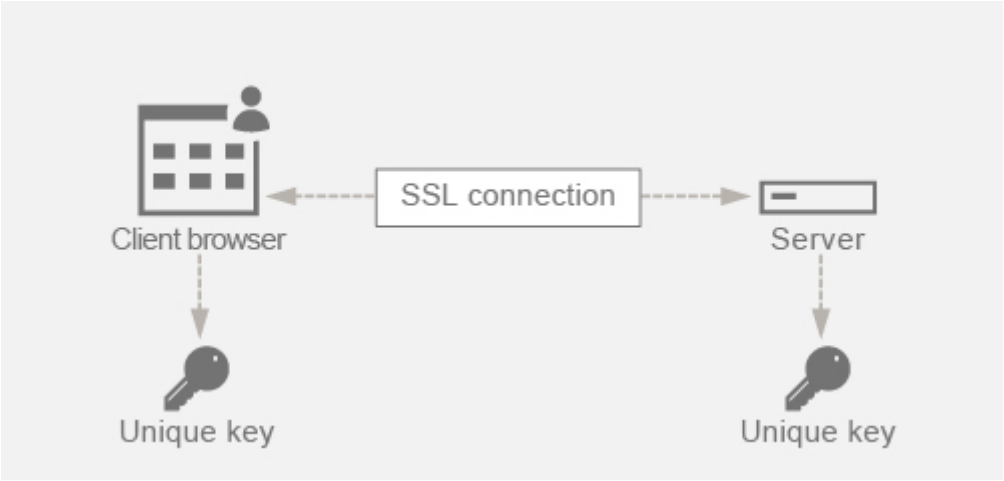
Perfect Forward Secrecy ensures protection of current SSL communications even if the session key of a web server is compromised at a later point in time.

Why do you need Perfect Forward Secrecy (PFS)?

An SSL connection is used to secure the data being passed between a client and a server. This connection begins with the SSL handshake that takes place between a client's browser and the contacted web server. It is during this handshake that the browser and the server exchange certain information

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

to arrive upon a session key which serves as a means to encrypt the data throughout the rest of the communication.



RSA is the most commonly used algorithm for key exchange. The browser uses the server's public key to encrypt and send across the pre-master secret to a server. This pre-master secret is used to arrive at the session key. The problem in the RSA key exchange approach is that if an attacker manages to get hold of the server's private key at any point in time in the future, then the attacker gets hold of the pre-master secret using which the session key can be obtained. This session key can now be used by the attacker to decrypt all the SSL conversations. This means that your historical SSL communication was secure earlier but they are no longer secure as the server's stolen private key can be used to arrive at the session key and thus decrypt any saved historical conversation as well.

The need is to be able to protect the past SSL communication even if the server's private key has been compromised. This is where configuring Perfect Forward Secrecy (PFS) comes to the rescue.

How does PFS help?

Perfect Forward Secrecy (PFS) protects the past SSL communication by having the client and server agree upon a new key for each session and keeping the computation of this session key a secret. It works on the basis that compromise of a server key must not result in compromise of the session key. Session key is derived separately at both ends and is never transferred over the wire. The session keys are also destroyed once the communication is complete. These facts ensure that even if someone gets access to the server's private key, they would not be able to arrive at the session key and hence would not be able to decrypt the past data.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Explanation with example

Assume that we are using DHE for attaining PFS. The DH algorithm ensures that even though a hacker gets hold of the server's private key, the hacker will not be able to arrive at the session key because the session key and the random numbers (used to arrive at the session key) are kept secret at both ends and never exchanged over the wire.
PFS can be achieved by using the Ephemeral Diffie-Hellman key exchange which creates new temporary keys for each SSL session.

The flip side of creating a key for each session is that it requires extra computation but this can be overcome by using the Elliptic Curve which has smaller key sizes.

Configure PFS on Citrix ADC appliance

PFS can be configured on a Citrix ADC by configuring DHE or ECDHE ciphers. These ciphers ensure that the secret session key created is not shared on the wire (DH algorithm) and that the session key remains alive only for a short time (Ephemeral). Both the configurations are explained in the following sections.

Note: Using ECDHE ciphers instead of DHE makes the communication more secure with smaller key sizes.

Configure DHE by using the GUI

1. Generate a DH key.
   a. Navigate to **Traffic Management > SSL > Tools**.
   b. Click **Create Diffie Helman (DH) Key**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: Generating a 2048-bit DH key can take up to 30 minutes.

2. Enable DH Param for the SSL virtual server and attach the DH key to the SSL virtual server.

   a. Navigate to **Configuration > Traffic Management > Virtual Servers**.

   b. Select the virtual server on which you want to enable DH.

   c. Click **Edit**, click **SSL Parameters**, and click **Enable DH Param**.

3. Bind the DHE ciphers to the virtual server.

   a. Navigate to **Configuration > Traffic Management > Virtual Servers**.

   b. Select the virtual server on which you want to enable DH and click the pencil icon to edit.

   c. Under **Advanced Settings**, click plus icon next to **SSL Ciphers** and select the DHE cipher groups and click **OK** to bind.

   Note: Ensure that the DHE ciphers are at the top of the cipher list bound to the virtual server.

Configure ECDHE by using the GUI

1. Bind the ECC curves to the SSL virtual server.

   a. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers**.

   b. Select the SSL virtual server which you want to edit, click **ECC Curve** and click **Add Binding**.

   c. Bind the required ECC curve to the virtual server.

2. Bind the ECDHE ciphers to the virtual server.

   a. Navigate to **Configuration > Traffic Management > Virtual Servers** and select the virtual server on which you want to enable DH.

   b. Click **Edit > SSL Ciphers** and select the ECDHE cipher groups and click **Bind**.

   Note: Ensure that the ECDHE ciphers are at the top of the cipher list bound to the virtual server.

Note: For each case verify that the Citrix ADC appliance supports the ciphers you would like to use for the communication.

Configure PFS using an SSL profile

Note: Option to configure PFS (cipher or ECC) using an SSL profile is introduced from 11.0 64.x release onwards. Ignore the following section if on older versions.

To enable PFS using an SSL profile, a similar configuration (as explained in earlier configuration sections) needs to be done but on the SSL profile instead of directly configuring on a virtual server.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure PFS using an SSL profile by using the GUI

1. Bind the ECC curves and the ECDHE ciphers on the SSL profile.

   Note: ECC curves are already bound by default to all the SSL profiles.

   a. Navigate to **System > Profiles > SSL Profiles** and choose the profile you want to enable PFS on.

   b. Bind the ECDHE ciphers.

2. Bind the SSL profile to the virtual server.

   a. Go to **Configuration > Traffic Management > Virtual Servers** and select the virtual server.

   b. Click the pencil icon to edit the SSL profile.

   c. Click **OK** and click **Done**.

Configure PFS using SSL using the CLI At the command prompt, type:

1. Bind ECC curves to the SSL profile.

```
bind sslprofile <SSLProfileName> -eccCurveName <Name_of_curve>
```

2. Bind the ECDHE cipher group.

```
bind sslprofile <SSLProfileName> cipherName <ciphergroupName>
```

3. Set the priority of the ECDHE cipher as 1.

```
set sslprofile <SSLProfileName> cipherName <ciphergroupName>
   cipherPriority <positive_integer>
```

4. Bind the SSL profile to the virtual server.

```
set SSL vserver <vservername> sslProfile <SSLProfileName>
```

ECDHE ciphers

December 29, 2023

All Citrix ADC appliances support the ECDHE cipher group on the front end and the back end. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies.

For more information about the builds and platforms that support these ciphers, see Ciphers available on the Citrix ADC appliances.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

ECDHE cipher suites use elliptical curve cryptography (ECC). Because of its smaller key size, ECC is especially useful in a mobile (wireless) environment or an interactive voice response environment, where every millisecond is important. Smaller key sizes save power, memory, bandwidth, and computational cost.

A Citrix ADC appliance supports the following ECC curves:

- P_256
- P_384
- P_224
- P_521

Note: If you upgrade from a build earlier than release 10.1 build 121.10, you must explicitly bind ECC curves to your existing SSL virtual servers and services. The curves are bound by default to any virtual servers and services that you create after the upgrade.

You can bind an ECC curve to SSL front end and back end entities. By default all four curves are bound, in the following order: P_256, P_384,P_224,P_521. To change the order, you must first unbind all the curves, and then bind them in the desired order.

Bind ECC curves to an SSL virtual server by using the CLI

At the command prompt, type:

```
bind ssl vserver <vServerName > -eccCurveName <eccCurveName >
```

Example:

```
bind ssl vserver  v1 -eccCurveName P_224

sh ssl vserver v1

Advanced SSL configuration for VServer v1:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED

9. Click **Close**.
10. Click **Done**.

Diffie-Hellman parameters generation and achieving PFS with DHE

May 26, 2023

The Diffie-Hellman (DH) key exchange is a way for two parties involved in an SSL transaction to agree upon a shared secret over an insecure channel. These parties have no prior knowledge about each other. This secret can be converted into cryptographic keying material for symmetric key cipher algorithms that require such a key exchange.

This feature is disabled by default. Configured the feature to support ciphers that use DH as the key exchange algorithm.

> **Note**:
>
> Generating 2048-bit DH parameters might take a long time (up to 30 minutes).

Generate DH parameters by using the CLI

At the command prompt, type the following command:

```
create ssl dhparam <dhFile> [<bits>] [-gen (2 | 5)]
```

Example:

```
create ssl dhparam Key-DH-1 512 -gen 2
```

Generate DH parameters by using the GUI

Navigate to **Traffic Management** > **SSL** and, in the **Tools** group, select **Create Diffie-Hellman (DH) key**, and **Configure SSL DH Param**.

> **Note:**
>
> For information about DH parameters, see Diffie-Hellman parameters.

Achieve perfect forward secrecy with DHE

Generating DH parameters is a CPU-intensive operation. In earlier releases, parameter generation, on a VPX appliance, took a long time because it was done in the software. Parameter generation is

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

optimized by setting the dhKeyExpSizeLimit parameter. You can set this parameter for an SSL virtual server or an SSL profile and then bind the profile to a virtual server.

You can maintain perfect forward secrecy (PFS) on Citrix ADC MPX appliances by setting the DH count equal to zero. As a result, DH parameters are generated for each transaction (minimum DHcount is 0) on Citrix ADC MPX appliances. Thee parameters are generated without a significant drop in performance, because the operation is optimized. Earlier, the minimum DH count allowed was 500. That is, you cannot regenerate the key for up to 500 transactions.

> **Limitation:**
>
> > On a Citrix ADC VPX appliance, if you set the DH count to zero, the DH parameters are not regenerated. Therefore, you must set the DH count to 500 to maintain PFS. The DH parameters are regenerated after 500 transactions.

Optimize DH parameters generation by using the CLI

At the command prompt, type commands 1 and 2, or type command 3:

```
1. add ssl profile <name> [-sslProfileType ( BackEnd | FrontEnd )] [-dhCount <positive_integer>] [-dh ( ENABLED | DISABLED) -dhFile <string>] [-dhKeyExpSizeLimit ( ENABLED | DISABLED)]
2. set ssl vserver <vServerName> [-sslProfile <string>]
```

```
3. set ssl vserver <vServerName> [-dh ( ENABLED | DISABLED) -dhFile <string>] [-dhCount <positive_integer>] [-dhKeyExpSizeLimit ( ENABLED | DISABLED )]
```

Optimize DH parameters generation by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable DH Key Expire Size Limit**.

Cipher redirection

September 14, 2021

During the SSL handshake, the SSL client (usually a web browser) announces the suite of ciphers that it supports, in the configured order of cipher preference. From that list, the SSL server then selects a cipher that matches its own list of configured ciphers.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

If the ciphers announced by the client does not match the ciphers configured on the SSL server, the SSL handshake fails. The failure is announced by a cryptic error message displayed in the browser. These messages rarely mention the exact cause of the error.

With cipher redirection, you can configure an SSL virtual server to deliver accurate, meaningful error messages when an SSL handshake fails. When an SSL handshake fails, the ADC appliance redirects the user to a previously configured URL or, if no URL is configured, displays an internally generated error page.

Configure cipher redirection by using the CLI

At the command prompt, type the following commands to configure cipher redirection and verify the configuration:

```
1 - set ssl vserver <vServerName> -cipherRedirect < ENABLED | DISABLED>
    -cipherURL < URL>
2 - show ssl vserver <vServerName>
```

Example:

```
1  set ssl vserver vs-ssl -cipherRedirect ENABLED -cipherURL http://
       redirectURl
2
3  Done
4
5  show ssl vserver vs-ssl
6
7  Advanced SSL configuration for VServer vs-ssl:
8  DH: DISABLED
9  Ephemeral RSA: ENABLED          Refresh Count: 1000
10 Session Reuse: ENABLED          Timeout: 600 seconds
11 Cipher Redirect: ENABLED        Redirect URL: http://redirectURl
12 SSLv2 Redirect: DISABLED
13 ClearText Port: 0
14 Client Auth: DISABLED
15 SSL Redirect: DISABLED
16 Non FIPS Ciphers: DISABLED
17 SNI: DISABLED
18 OCSP Stapling: DISABLED
19 HSTS: DISABLED
20 HSTS IncludeSubDomains: NO
21 HSTS Max-Age: 0
22 SSLv2: DISABLED SSLv3: ENABLED  TLSv1.0: ENABLED TLSv1.2: ENABLED
       TLSv1.2: ENABLED
23     1)      CertKey Name: Auth-Cert-1       Server Certificate
24     1)      Cipher Name: DEFAULT
25             Description: Predefined Cipher Alias
26 Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure cipher redirection by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable Cipher Redirect**, and specify a redirect URL.

Use hardware and software to improve ECDHE and ECDSA cipher performance

September 14, 2021

> **Note:**
>
> This enhancement is applicable only to the following platforms:
>
> - MPX/SDX 11000
> - MPX/SDX 14000
> - MPX 22000, MPX 24000, and MPX 25000
> - MPX/SDX 14000 FIPS

Previously, ECDHE and ECDSA computation on a Citrix ADC appliance was performed only on the hardware (Cavium chips), which limited the number of SSL sessions at any given time. With this enhancement, some operations are also performed in the software. That is, processing is done both on the Cavium chips and on the CPU cores to improve ECDHE and ECDSA cipher performance.

The processing is first performed in software, up to the configured software crypto threshold. After this threshold is reached, the operations are offloaded to the hardware. Therefore, this hybrid model uses both hardware and software to improve SSL performance. You can enable the hybrid model by setting the "softwareCryptoThreshold"parameter to suit your requirement. To disable the hybrid model, set this parameter to 0.

Benefits are greatest if the current CPU utilization is not too high, because the CPU threshold is not exclusive to ECDHE and ECDSA computation. For example, if the current workload on the appliance consumes 50% of the CPU cycles, and the threshold is set to 80%, ECDHE and ECDSA computation can only use 30%. After the configured software crypto threshold of 80% is reached, further ECDHE and ECDSA computation is offloaded to the hardware. In that case, actual CPU utilization might exceed 80%, because performing ECDHE and ECDSA computations in hardware consumes some CPU cycles.

Enable the hybrid model by using the CLI

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
set ssl parameter -softwareCryptoThreshold <positive_integer>

Synopsis:

softwareCryptoThreshold:

Citrix ADC CPU utilization threshold (as a percentage) beyond which
   crypto operations are not done in software. A value of zero implies
   that CPU is not utilized for doing crypto in software.

Default = 0

Min = 0

Max = 100
```

Example:

```
set ssl parameter - softwareCryptoThreshold 80
Done

show ssl parameter
Advanced SSL Parameters

SSL quantum size                  : 8 KB
Max CRL memory size               : 256 MB
Strict CA checks                  : NO
Encryption trigger timeout        : 100 ms
Send Close-Notify                 : YES
Encryption trigger packet c       : 45
Deny SSL Renegotiation            : ALL
Subject/Issuer Name Insertion Format : Unicode
OCSP cache size                   : 10 MB
Push flag                         : 0x0 (Auto)
Strict Host Header check for SNI enabled SSL sessions : NO
PUSH encryption trigger timeout   : 1 ms
Crypto Device Disable Limit       : 0
Global undef action for control policies : CLIENTAUTH
Global undef action for data policies : NOOP
Default profile                   : DISABLED
Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors    : NO
Disable TLS 1.1/1.2 for dynamic and VPN services : NO
Software Crypto acceleration CPU Threshold : 80
Signature and Hash Algorithms supported by TLS1.2 : ALL
```

Enable the hybrid model by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Change advanced SSL settings**.
2. Enter a value for **Software Crypto Threshold (%)**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Set an SNMP alarm for ECDHE exchange rate

ECDHE-based key exchange can cause the transactions per second on the appliance to drop. From release 13.0 build 52.x, you can configure an SNMP alarm for ECDHE-based transactions. In this alarm, you can set the threshold and normal limits for the ECDHE exchange rate. A new counter `nsssl_tot_sslInfo_ECDHE_Tx` is added. This counter is the sum of all the ECDHE-based transaction counters on the front-end and back-end of the appliance. When the ECDHE-based key exchange crosses the configured limits an SNMP trap is sent. Another trap is sent when the value is back to the configured normal value.

Set an SNMP alarm for ECDHE exchange rate using the CLI

At the command prompt, type:

```
set snmp alarm ECDHE-EXCHANGE-RATE -logging ( ENABLED | DISABLED ) -
    severity <severity>
 -state ( ENABLED | DISABLED ) -thresholdValue <positive_integer>  [-
     normalValue <positive_integer>] -time <secs>
```

Example:

```
set snmp alarm ECDHE-EXCHANGE-RATE -logging eNABLED -severity critical
    -state eNABLED -thresholdValue 100 -normalValue 50
```

ECDSA cipher suites support

September 14, 2021

ECDSA cipher suites use elliptical curve cryptography (ECC). Because of its smaller size, it is helpful in environments where processing power, storage space, bandwidth, and power consumption are constrained.

When the ECDHE_ECDSA cipher group is used, the server's certificate must contain an ECDSA-capable public key.

The following table lists the ECDSA ciphers that are supported on the Citrix ADC MPX and SDX appliances with N3 chips, Citrix ADC VPX appliances, MPX 5900/26000, and MPX/SDX 8900/15000 appliances.

ECDSA/RSA cipher and certificate selection

You can bind both ECDSA and RSA server certificates at the same time to an SSL virtual server. When both ECDSA and RSA certificates are bound to the virtual server, it automatically selects the appropriate server certificate to present to the client. If the client cipher list includes RSA ciphers, but does not include ECDSA ciphers, the virtual server presents the RSA server certificate. If both ciphers are present in the client's list, then the server certificate presented depends on the cipher priority set on the virtual server. That is, if RSA has a higher priority, the RSA certificate is presented. If ECDSA has a higher priority, the ECDSA certificate is presented to the client.

Client authentication by using an ECDSA or an RSA certificate

For client authentication, the CA certificate bound to the virtual server can be ECDSA or RSA signed. The appliance supports a mixed certificate chain. For example, the following certificate chain is supported.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Client certificate (ECDSA) <-> CA certificate (RSA) <-> Intermediate certificate (RSA) <-> Root certificate (RSA)

The following table shows the elliptical curves supported on the different Citrix ADC appliances with ECDSA cipher groups and ECDSA certificates:

Elliptical curves	Platforms supported
prime256v1	All platforms, including FIPS.
secp384r1	All platforms, including FIPS.
secp521r1	MPX 5900, MPX/SDX 8900, MPX/SDX 15000, MPX/SDX 26000, VPX
secp224r1	MPX 5900, MPX/SDX 8900. MPX/SDX 15000, MPX/SDX 26000, VPX

Create an ECDSA certificate-key pair

You can create an ECDSA certificate-key pair directly on a Citrix ADC appliance by using the CLI or the GUI. Earlier, you were able to install and bind an ECC certificate-key pair on the appliance, but you had to use OpenSSL to create a certificate-key pair.

Only P_256 and P_384 curves are supported.

> **Note**
>
> This support is available on all platforms except MPX 9700/1050/12500/15500.

To create an ECDSA certificate-key pair by using the CLI:

At the command prompt, type:

```
create ssl ecdsaKey <keyFile> -curve ( P_256 | P_384 ) [-keyform ( DER
   | PEM )] [-des | -des3] {
 -password  }
  [-pkcs8]
```

Example:

```
create ecdsaKey ec_p256.ky -curve P_256 -pkcs8
Done
create ecdsaKey ec_p384.ky -curve P_384
Done
```

To create an ECDSA certificate-key pair by using the GUI:

1. Navigate to **Traffic Management > SSL > SSL Files > Keys** and click **Create ECDSA Key**.
2. To create a key in PKCS#8 format, select **PKCS8**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure user-defined cipher groups on the ADC appliance

September 14, 2021

A cipher group is a set of cipher suites that you bind to an SSL virtual server, service, or service group on the Citrix ADC appliance. A cipher suite comprises a protocol, a key exchange (Kx) algorithm, an authentication (Au) algorithm, an encryption (Enc) algorithm, and a message authentication code (Mac) algorithm. Your appliance ships with a predefined set of cipher groups. When you create an SSL service or SSL service group, the ALL cipher group is automatically bound to it. However, when you create an SSL virtual server or a transparent SSL service, the DEFAULT cipher group is automatically bound to it. In addition, you can create a user-defined cipher group and bind it to an SSL virtual server, service, or service group.

Note: If your MPX appliance does not have any licenses, then only the EXPORT cipher is bound to your SSL virtual server, service, or service group.

To create a user-defined cipher group, first you create a cipher group and then you bind ciphers or cipher groups to this group. If you specify a cipher alias or a cipher group, all the ciphers in the cipher alias or group are added to the user-defined cipher group. You can also add individual ciphers (cipher suites) to a user-defined group. However, you cannot modify a predefined cipher group. Before removing a cipher group, unbind all the cipher suites in the group.

Binding a cipher group to an SSL virtual server, service, or service group, appends the ciphers to the existing ciphers that are bound to the entity. To bind a specific cipher group to the entity, you must first unbind the ciphers or cipher group that is bound to the entity. Then bind the specific cipher group to the entity. For example, to bind only the AES cipher group to an SSL service, you perform the following steps:

1. Unbind the default cipher group ALL that is bound by default to the service when the service is created.

   ```
   unbind ssl service <service name> -cipherName ALL
   ```

2. Bind the AES cipher group to the service

   ```
   bind ssl service <Service name> -cipherName AE
   ```

   If you want to bind the cipher group DES in addition to AES, at the command prompt, type:

   ```
   bind ssl service <service name> -cipherName DES
   ```

Note: The free Citrix ADC virtual appliance supports only the DH cipher group.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure a user-defined cipher group by using the CLI

At the command prompt, type the following commands to add a cipher group, or to add ciphers to a previously created group, and verify the settings:

```
add ssl cipher <cipherGroupName>
bind ssl cipher <cipherGroupName> -cipherName <cipherGroup/cipherName>
show ssl cipher <cipherGroupName>
```

Example:

```
add ssl cipher test

Done

bind ssl cipher test -cipherName ECDHE

Done

sh ssl cipher test

1)      Cipher Name: TLS1-ECDHE-RSA-AES256-SHA  Priority : 1

47 Done
48
49 bind ssl cipher test -cipherName TLS1-ECDHE-RSA-DES-CBC3-SHA
```

Unbind ciphers from a cipher group by using the CLI

At the command prompt, type the following commands to unbind ciphers from a user-defined cipher group, and verify the settings:

```
1 show ssl cipher <cipherGroupName>
2
3 unbind ssl cipher <cipherGroupName> -cipherName <string>
4
5 show ssl cipher <cipherGroupName>
```

Remove a cipher group by using the CLI

Note: You cannot remove a built-in cipher group. Before removing a user-defined cipher group, make sure that the cipher group is empty.

At the command prompt, type the following commands to remove a user-defined cipher group, and verify the configuration:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
rm ssl cipher <userDefCipherGroupName> [<cipherName> ...]
show ssl cipher <cipherGroupName>
```

Example:

```
rm ssl cipher test Done

sh ssl cipher test ERROR: No such resource [cipherGroupName, test]
```

Configure a user-defined cipher group by using the GUI

1. Navigate to **Traffic Management > SSL > Cipher Groups**.
2. Click **Add**.
3. Specify a name for the cipher group.
4. Click **Add** to view the available ciphers and cipher groups.
5. Select a cipher or cipher group, and click the arrow button to add them.
6. Click **Create**.
7. Click **Close**.

To bind a cipher group to an SSL virtual server, service, or service group by using the CLI:

At the command prompt, type one of the following:

```
bind ssl vserver <vServerName> -cipherName <string>

bind ssl service <serviceName> -cipherName <string>

bind ssl serviceGroup <serviceGroupName> -cipherName <string>
```

Example:

```
bind ssl vserver ssl_vserver_test -cipherName test
Done

bind ssl service  nshttps -cipherName test
Done

bind ssl servicegroup  ssl_svc  -cipherName test
Done
```

To bind a cipher group to an SSL virtual server, service, or service group by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.

   For service, replace virtual servers with services. For service groups, replace virtual servers with service groups.

   Open the virtual server, service, or service group.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. In **Advanced Settings**, select **SSL Ciphers**.
3. Bind a cipher group to the virtual server, service, or service group.

Binding individual ciphers to an SSL virtual server or service

You can also bind individual ciphers, instead of a cipher group, to a virtual server or service.

To bind a cipher by using the CLI:
At the command prompt, type:

```
bind ssl vserver <vServerName> -cipherName <string>
bind ssl service <serviceName> -cipherName <string>
```

Example:

```
bind ssl vserver v1 -cipherName TLS1.2-ECDHE-RSA-AES256-GCM-SHA384
Done

bind ssl service sslsvc -cipherName TLS1.2-ECDHE-RSA-AES256-GCM-SHA384
Done
```

To bind a cipher to an SSL virtual server by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select an SSL virtual server and click **Edit**.
3. In **Advanced Settings**, select **SSL Ciphers**.
4. In **Cipher Suites**, select **Add**.
5. Search for the cipher in the available list and click the arrow to add it to the configured list.
6. Click **OK**.
7. Click **Done**.

To bind a cipher to an SSL service, repeat the preceding steps after replacing virtual server with service.

Server certificate support matrix on the ADC appliance

December 16, 2021

From release 13.0 build 41.x, the ADC appliance supports server certificate messages that are fragmented into more than one record if the total size is within 32 KB. Earlier, the maximum supported size was 16 KB and fragmentation was not supported.

The Citrix ADC appliance supports the following server certificates.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Table 1: Support on front-end (FE) and back-end (BE) service

Server certificate/-Platform	MPX/SDX (N2 CHIPS) FE	MPX/SDX (N2 CHIPS) BE	MPX/SDX (N3 CHIPS) FE	MPX/SDX (N3 CHIPS) BE	VPX FE	VPX BE
MD5	Y	Y	Y	Y	Y	Y
SHA1	Y	Y	Y	Y	Y	Y
SHA224	Y	Y	Y	Y	Y	Y
SHA256	Y	Y	Y	Y	Y	Y

> **Notes**
>
> - 4k certificates require higher CPU cycles and might affect the performance of low-end appliances.
> - In release 11.1 and earlier, a Citrix ADC appliance supports the following "signature algorithms"extensions in the back end client hello message: RSA-MD5, RSA-SHA1, and RSA-SHA256.
>
> The Citrix ADC appliance does not support SHA 384 and SHA 512 signature algorithms extensions. Therefore some servers, such as Windows IIS servers, reset the connection.
> - Starting release 12.0, a Citrix ADC appliance supports all the signature_algorithms extensions.

Client authentication or Mutual TLS (mTLS)

January 3, 2022

In a typical SSL transaction, the client that is connecting to a server over a secure connection checks the validity of the server. To do so, it checks the server's certificate before initiating the SSL transaction. Sometimes, however, you might want to configure the server to authenticate the client that is connecting to it.

Note: From release 13.0 build 41.x, the Citrix ADC appliance supports certificate request messages that are fragmented into more than one record provided the total size is within 32 KB. Earlier, the maximum supported size was 16 KB and fragmentation was not supported.

With client authentication enabled on an SSL virtual server, the Citrix ADC appliance asks for the client certificate during the SSL handshake. The appliance checks the certificate presented by the client for normal constraints, such as the issuer signature and expiration date.

> **Note**
>
> For the appliance to verify issuer signatures, the certificate of the CA that issued the client certificate must be:
>
> - Installed on the appliance.
> - Bound to the virtual server that the client is transacting with.

If the certificate is valid, the appliance allows the client to access all secure resources. But if the certificate is invalid, the appliance drops the client request during the SSL handshake.

The appliance verifies the client certificate by first forming a chain of certificates, starting with the client certificate, and ending with the root CA certificate for the client (for example, Verisign). The root

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

CA certificate might contain one or more intermediate CA certificates (if the root CA does not directly issue the client certificate).

Before you enable client authentication on the Citrix ADC appliance, make sure that a valid client certificate is installed on the client. Then, enable client authentication for the virtual server that handles the transactions. Finally, bind the certificate of the CA that issued the client certificate to the virtual server on the appliance.

Note: A Citrix ADC MPX appliance supports a certificate-key pair size from 512 bits to 4096 bits. The certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

On an SDX appliance, if an SSL chip is assigned to a VPX instance, the certificate-key pair size support of an MPX appliance applies. Otherwise, the normal certificate-key pair size support of a VPX instance applies.

A Citrix ADC virtual appliance (VPX instance) supports certificates of at least 512 bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate
- 4096-bit certificate on the physical server

Note: From release 13.0 build 79.x, client authentication with 4096-bit RSA client certificate is supported during an SSL handshake on the VPX platform.

Notes:

- For MPX FIPS limitations, see MPX FIPS limitations.
- For SDX FIPS limitations, see SDX FIPS limitations.

Provide the client certificate

Before you configure client authentication, a valid client certificate must be installed on the client. A client certificate includes details about the specific client system that creates secure sessions with the Citrix ADC appliance. Each client certificate is unique and must be used by only one client system.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Whether you obtain the client certificate from a CA, use an existing client certificate, or generate a client certificate on the Citrix ADC appliance, you must convert the certificate to the correct format. On the Citrix ADC appliance, certificates are stored in either the PEM or DER format and must be converted to PKCS#12 format before they are installed on the client system. After converting the certificate and transferring it to the client system, ensure that it is installed on that system and configured for the client application. The application, such as a web browser, must be part of the SSL transactions.

For instructions on how to convert a certificate from PEM or DER format to PKCS#12 format, see Import and convert SSL files.

For instructions on how to generate a client certificate, see Create a certificate.

Enable client-certificate based authentication

By default, client authentication is disabled on the Citrix ADC appliance, and all SSL transactions proceed without authenticating the client. You can configure client authentication to be either optional or mandatory as part of the SSL handshake.

If client authentication is optional, the appliance requests the client certificate but proceeds with the SSL transaction even if the client presents an invalid certificate. If client authentication is mandatory, the appliance terminates the SSL handshake if the SSL client does not provide a valid certificate.

Caution: Citrix recommends that you define proper access control policies before changing the client-certificate-based authentication check to optional.

Note: Client authentication is configured for individual SSL virtual servers, not globally.

Enable client-certificate based authentication by using the CLI

At the command prompt, type the following commands to enable the client-certificate-based authentication and verify the configuration:

```
set ssl vserver <vServerName> [-clientAuth (ENABLED | DISABLED)] [-
   clientCert (MANDATORY | OPTIONAL)]
show ssl vserver <vServerName>
```

Example:

```
set ssl vserver vssl -clientAuth ENABLED -clientCert Mandatory
Done
show ssl vserver vssl

Advanced SSL configuration for VServer vssl:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: ENABLED Client Cert Required: Mandatory
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        OCSP Stapling: DISABLED
        HSTS: DISABLED
        HSTS IncludeSubDomains: NO
        HSTS Max-Age: 0
SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.2: ENABLED TLSv1
   .2: ENABLED

1) CertKey Name: sslckey Server Certificate

1) Policy Name: client_cert_policy Priority: 0

1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done
```

Enable client-certificate based authentication by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the SSL Parameters section, select Client Authentication, and in the Client Certificate list, select Mandatory.

> **Note:**
>
> If client authentication is set to mandatory and if the client certificate contains policy extensions, certificate validation fails. From release 12.0-56.x, you can set a parameter in the front-end SSL profile to skip this check. The parameter is disabled by default. That is, the check is performed by default.

Skip the policy extension check during client authentication by using the CLI

At the command prompt, type:

```
set ssl profile ns_default_ssl_profile_frontend -clientauth ENABLED -
   skipClientCertPolicyCheck ENABLED

Parameter

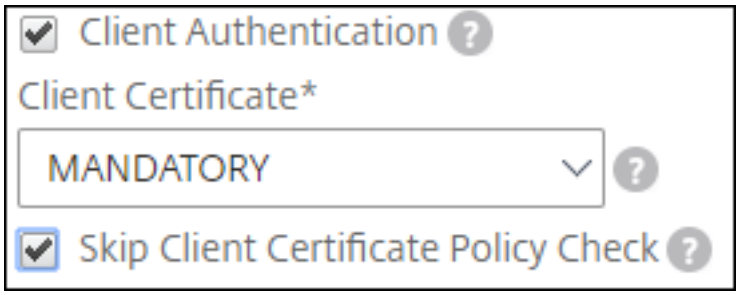
skipClientCertPolicyCheck

             Control policy extension check, if present inside the
                X509 certificate chain. Applicable only if client
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
                    authentication is enabled and client certificate is
                    set to mandatory. Possible values functions as follows
                    :

- ENABLED: Skip the policy check during client authentication.



- DISABLED: Perform policy check during client authentication.

Possible values: ENABLED, DISABLED

Default: DISABLED
```

Skip the policy extension check during client authentication by using the GUI

1. Navigate to **System** > **Profiles** > **SSL Profiles**.
2. Create a new front-end profile or edit an existing front-end profile.
3. Verify that client authentication is enabled and client certificate is set to mandatory.
4. Select **Skip Client Certificate Policy Check**.

Bind CA certificates to the virtual server

A CA whose certificate is present on the Citrix ADC appliance must issue the client certificate used for client authentication. Bind this certificate to the Citrix ADC virtual server that carries out client authentication.

Bind the CA certificate to the SSL virtual server in such a way that the appliance can form a complete certificate chain when it verifies the client certificate. Otherwise, certificate chain formation fails and the client is denied access even if its certificate is valid.

You can bind CA certificates to the SSL virtual server in any order. The appliance forms the proper order during client certificate verification.

For example, if the client presents a certificate issued by **CA_A**, where **CA_A** is an intermediate CA whose certificate is issued by **CA_B**, whose certificate is in turn issued by a trusted root CA, **Root_CA**, a chain of certificates that contain all three of these certificates must be bound to the virtual server on the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

For instructions on binding one or more certificates to the virtual server, see Bind the certificate-key pair to the SSL virtual server.

For instructions on creating a chain of certificates, see Create a chain of certificates.

Stricter control on client certificate validation

The Citrix ADC appliance accepts valid Intermediate-CA certificates if issues by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and that Root-CA validates any intermediate certificate sent with the client certificate, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the **ClientAuthUseBoundCAChain** setting in the SSL profile bound to the virtual server. The handshake fails if one of the CA certificates bound to the virtual server has not signed the client certificate.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, the Citrix ADC appliance only accepts clientcert1.

Enable stricter control on client certificate validation by using the CLI

At the command prompt, type:

```
set ssl profile <name> -ClientAuthUseBoundCAChain Enabled
```

Enable stricter control on client certificate validation by using the GUI

1. Navigate to **System** > **Profiles**, select the **SSL Profiles** tab, and create an SSL profile, or select an existing profile.
2. Select **Enable Client Authentication using bound CA Chain**.

Server authentication

September 14, 2021

Since the Citrix ADC appliance performs SSL offload and acceleration on behalf of a web server, the appliance does not usually authenticate the Web server's certificate. However, you can authenticate the server in deployments that require end-to-end SSL encryption.

In such a situation, the appliance becomes the SSL client and carries out a secure transaction with the SSL server. It verifies that a CA whose certificate is bound to the SSL service has signed the server certificate, and checks the validity of the server certificate.

To authenticate the server, enable server authentication and bind the certificate of the CA that signed the server's certificate to the SSL service on the ADC appliance. When binding the certificate, you must specify the bind as a CA option.

Enable (or disable) server certificate authentication

You can use the CLI and the GUI to enable and disable server certificate authentication.

Enable (or disable) server certificate authentication using the CLI

At the command prompt, type the following commands to enable server certificate authentication and verify the configuration:

```
set ssl service <serviceName> -serverAuth ( ENABLED | DISABLED )
show ssl service <serviceName>
```

Example:

```
set ssl service ssl-service-1 -serverAuth ENABLED
```

```
show ssl service ssl-service-1

            Advanced SSL configuration for Back-end SSL Service ssl-
               service-1:`
            DH: DISABLED
            Ephemeral RSA: DISABLED
            Session Reuse: ENABLED          Timeout: 300 seconds
            Cipher Redirect: DISABLED
            SSLv2 Redirect: DISABLED
            Server Auth: ENABLED
            SSL Redirect: DISABLED
            Non FIPS Ciphers: DISABLED
            SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
13      1)      Cipher Name: ALL
14              Description: Predefined Cipher Alias
15  Done
```

Enable (or disable) server certificate authentication by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open an SSL service.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a Common Name.
3. In Advanced Settings, select Certificates, and bind a CA certificate to the service.

Bind the CA certificate to the service by using the CLI

At the command prompt, type the following commands to bind the CA certificate to the service and verify the configuration:

```
1  bind ssl service <serviceName> -certkeyName <string> -CA
2
3  show ssl service <serviceName>
```

Example:

```
1  bind ssl service ssl-service-1 -certkeyName samplecertkey -CA
```

```
1  show ssl service ssl-service-1
2
3              Advanced SSL configuration for Back-end SSL Service ssl-
                   service-1:
4              DH: DISABLED
5              Ephemeral RSA: DISABLED
6              Session Reuse: ENABLED          Timeout: 300 seconds
7              Cipher Redirect: DISABLED
8              SSLv2 Redirect: DISABLED
9              Server Auth: ENABLED
10             SSL Redirect: DISABLED
11             Non FIPS Ciphers: DISABLED
12             SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED
13     1)      CertKey Name: samplecertkey     CA Certificate
           CRLCheck: Optional
14     1)      Cipher Name: ALL
15             Description: Predefined Cipher Alias
16 Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure a common name for server certificate authentication

In end-to-end encryption with server authentication enabled, you can include a common name in the configuration of an SSL service or service group. The name that you specify is compared to the common name in the server certificate during an SSL handshake. If the two names match, the handshake is successful.
If the common names do not match, the common name specified for the service or service group is compared to the values in the subject alternative name (SAN) field in the certificate. If it matches one of those values, the handshake is successful. This configuration is especially useful if there are, for example, two servers behind a firewall and one of the servers spoofs the identity of the other. If the common name is not checked, a certificate presented by either server is accepted if the IP address matches.

Note: Only domain name, URL, and email ID DNS entries in the SAN field are compared.

Configure common-name verification for an SSL service or service group by using the CLI

At the command prompt, type the following commands to specify server authentication with common-name verification and verify the configuration:

1. To configure a common name in a service, type:

```
set ssl service <serviceName> -commonName <string> -serverAuth
   ENABLED
show ssl service <serviceName>
```

2. To configure a common name in a service group, type:

```
set ssl serviceGroup <serviceGroupName> -commonName <string> -
   serverAuth ENABLED
show ssl serviceGroup <serviceGroupName>
```

Example:

```
> set ssl service svc1 -commonName xyz.com -serverAuth ENABLED
```

```
show ssl service svc

     Advanced SSL configuration for Back-end SSL Service svc1:
     DH: DISABLED
     Ephemeral RSA: DISABLED
     Session Reuse: ENABLED Timeout: 300 seconds
     Cipher Redirect: DISABLED
     SSLv2 Redirect: DISABLED
     Server Auth: ENABLED Common Name: www.xyz.com
     SSL Redirect: DISABLED
     Non FIPS Ciphers: DISABLED
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
12       SNI: DISABLED
13       SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
14      1) CertKey Name: cacert CA Certificate OCSPCheck: Optional
15      1) Cipher Name: ALL
16       Description: Predefined Cipher Alias
17  Done
```

Configure common-name verification for an SSL service or service group by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services** or Navigate to **Traffic Management > Load Balancing > Service Groups**, and open a service or service group.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a common name.

SSL actions and policies

September 14, 2021

An SSL policy evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). Configure the actions before creating the policies, so that you can specify an action when you create a policy. To put a policy into effect, do one of the following:

- Bind the policy to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server.
- Bind the policy globally, so that it applies to all traffic flowing through the appliance.

SSL actions define SSL settings that you can apply to the selected requests. You associate an action with one or more policies. Data in client connection requests or responses is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression).

You can configure classic policies with classic expressions and default syntax policies with default syntax expressions for SSL.

Note: Users who are not experienced in configuring policies at the CLI usually find using the configuration utility to be considerably easier.

You can associate a user-defined action or a built-in action to a default syntax policy. Classic policies allow only user-defined actions. In default syntax policy, you can also group policies under a policy label, in which case they are applied only when invoked from another policy.

Common uses of SSL actions and policies include per-directory client authentication, support for Outlook web access, and SSL-based header insertions. SSL-based header insertions contain SSL settings required by a server whose SSL processing has been offloaded to the Citrix ADC appliance.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

SSL policies

September 14, 2021

Policies on the Citrix ADC appliance help identify specific connections that you want to process. The processing is based on the actions that are configured for that particular policy. Once you create the policy and configure an action for it, you must do one of the following:

- Bind the policy to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server.
- Bind the policy globally, so that it applies to all traffic flowing through any virtual server configured on the Citrix ADC appliance.

The Citrix ADC appliance SSL feature supports default syntax (advanced) policies. For a complete description of default syntax expressions, how they work, and how to configure them manually, see Policies and Expressions.

> **Note:**
>
> Users who are not experienced in configuring policies at the CLI usually find using the configuration utility considerably easier.

SSL policies require that you create an action before creating a policy, so that you can specify the actions when you create the policies.
In SSL default syntax policies, you can also use the built-in actions. For more information about built-in actions, see SSL built-in actions and user-defined actions.

SSL default syntax policies

An SSL default syntax policy, also known as an advanced policy, defines a control or a data action to be performed on requests. SSL policies can therefore be categorized as control policies and data policies:

- **Control policy**. A control policy uses a control action, such as forcing client authentication. Note: In release 10.5 or later, deny SSL renegotiation (denySSLReneg) is set, by default, to ALL. However, control policies, such as CLIENTAUTH, trigger a renegotiation handshake. If you use such policies, you must set denySSLReneg to NO.
- **Data policy**. A data policy uses a data action, such as inserting some data into the request.

The essential components of a policy are an expression and an action. The expression identifies the requests on which the action is to be performed.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

You can configure a default syntax policy with a built-in action or a user-defined action. You can configure a policy with a built-in action without creating a separate action. However, to configure a policy with a user-defined action, first configure the action and then configure the policy.

You can specify an extra action, called an UNDEF action, to be performed when applying the expression to a request has an undefined result.

SSL policy configuration

You can configure an SSL default syntax policy by using the CLI and the GUI.

Configure an SSL policy by using the CLI

At the command prompt, type:

```
add ssl policy <name> -rule <expression> -Action <string> [-undefAction
    <string>] [-comment <string>]
```

Configure an SSL policy by using the GUI

Navigate to **Traffic Management > SSL > Policies** and, on the **Polices** tab, click *Add*.

Support for SSL policies with TLS1.3 protocol

From release 13.0 build 71.x and later, support is added for SSL policies with the TLS1.3 protocol. When the TLSv1.3 protocol is negotiated for a connection, policy rules that inspect TLS data received from the client now trigger the configured action.

For example, if the following policy rule returns true, the traffic is forwarded to the virtual server defined in the action.

```
add ssl action action1 -forward vserver2
add ssl policy pol1 -rule client.ssl.client_hello.sni.contains( " xyz " )
    -action action1
```

Limitations

- Control policies are not supported.
- The following actions are not supported:
  - DOCLIENTAUTH

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- NOCLIENTAUTH
- caCertGrpName
- clientCertVerification
- ssllogProfile

SSL built-in actions and user-defined actions

September 14, 2021

Unless you need only the built-in actions in your policies, you have to create the actions before creating the policies. Then, you can specify the actions when you create the policies. The built-in actions are of two types, control actions and data actions. You use control actions in control policies, and data actions in data policies.

The built-in control actions are:

- DOCLIENTAUTH—Perform client certificate authentication. (Not supported for TLS1.3)
- NOCLIENTAUTH—Do not perform client certificate authentication. (Not supported for TLS1.3)

The built-in data actions are:

- RESET—Close the connection by sending an RST packet to the client.
- DROP—Drop all packets from the client. The connection remains open until the client closes it.
- NOOP—Forward the packet without performing any operation on it.

Note: Any dependent actions to client authentication, such as clientCertVerification and ssllogProfile, are not supported with the TLS 1.3 protocol.

You can create user-defined data actions. If you enable client authentication, you can create an SSL action to insert client-certificate data into the request header before forwarding the request to the web server.

If a policy evaluation results in an undefined state, an UNDEF action is performed. For either a data policy or a control policy, you can specify RESET, DROP, or NOOP as the UNDEF action. For a control policy, you also have the option of specifying DOCLIENTAUTH or NOCLIENTAUTH.

Examples of built-in actions in a policy

In the following example, if the client sends a cipher other than an EXPORT category cipher, the Citrix ADC appliance requests client authentication. The client has to provide a valid certificate for a successful transaction.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add ssl policy pol1 -rule CLIENT.SSL.CIPHER_EXPORTABLE.NOT -reqAction
    DOCLIENTAUTH
```

The following examples assume that client authentication is enabled.

If the version in the certificate provided by the user matches the version in the policy, no action is taken and the packet is forwarded:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -
    reqAction NOOP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is dropped:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -
    reqAction DROP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is reset:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -
    reqAction RESET
```

Client certificate verification with policy based client authentication

You can set client certificate verification to mandatory or option when you have configured policy based client authentication. Default is mandatory.

Set client certificate verification to optional using the CLI

At the command prompt, type:

```
add ssl action <name> ((-clientAuth ( DOCLIENTAUTH | NOCLIENTAUTH ) [-
    clientCertVerification ( Mandatory | Optional )]
```

Example:

```
add ssl action sslact -clientauth DOCLIENTAUTH -clientcertverification
    OPTIONAL
```

Set client certificate verification to optional using the GUI

1. Navigate to **Traffic Management > SSL > Policies**.
2. On the **SSL Actions** tab, click **Add**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

3. Specify a name and in the **Client Certificate Verification** list, select **Optional**.

User-defined SSL actions

In addition to built-in actions, you can also configure other SSL actions depending on your deployment. These actions are called user-defined actions.

Configure a user-defined SSL action by using the CLI

At the command prompt, type the following commands to configure an action and verify the configuration:

```
add SSL action <name> -clientAuth(DOCLIENTAUTH | NOCLIENTAUTH) -
    clientCert (ENABLED | DISABLED) certHeader <string> -clientHeader <
    string> -clientCertSerialNumber (ENABLED | DISABLED) -
    certSerialHeader <string> -clientCertSubject (ENABLED | DISABLED) -
    certSubjectHeader <string> -clientCertHash (ENABLED | DISABLED) -
    certHashHeader <string> -clientCertIssuer (ENABLED | DISABLED) -
    certIssuerHeader <string> -sessionID (ENABLED | DISABLED) -
    sessionIDheader <string> -cipher (ENABLED | DISABLED) -cipherHeader
    <string> -clientCertNotBefore (ENABLED | DISABLED) -
    certNotBeforeHeader <string> -clientCertNotAfter (ENABLED | DISABLED
    ) -certNotAfterHeader <string> -OWASupport (ENABLED | DISABLED)
```

```
show ssl action [<name>]
```

Example:

```
add ssl action Action-SSL-ClientCert -clientCert ENABLED -certHeader "X
    -Client-Cert"
```

```
show ssl action Action-SSL-ClientCert

1)      Name: Action-SSL-ClientCert
        Data Insertion Action:
        Cert Header: ENABLED            Cert Tag: X-Client-Cert
Done
```

Configure a user-defined SSL action by using the GUI

Navigate to **Traffic Management > SSL > Policies** and, on the **Actions** tab, click **Add**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure an SSL action to forward client traffic to another virtual server

Admins can configure an SSL action to forward the client traffic received on an SSL virtual server to another virtual server to avoid SSL offloading. Or for terminating the connection on the ADC appliance. This virtual server can be of the type: SSL, TCP, or SSL_BRIDGE. For example, admins can choose to forward the request to another virtual server for further action instead of terminating the connection if any of the following cases:

- The appliance does not have a certificate.
- The appliance does not support a specific cipher.

To achieve the above, a new bind point 'CLIENTHELLO_REQ'is added to evaluate client traffic when a client hello is received. If the policy bound to the virtual server receiving client traffic evaluates to true after parsing the client hello, the traffic is forwarded to another virtual server. If this virtual server is of type SSL, it performs the handshake. If this virtual server is of type TCP or SSL_BRIDGE, the back-end server performs the handshake.

In release 12.1-49.x, only the forward and reset actions are supported for the CLIENTHELLO_REQ bind point. The following expression prefixes are available:

- CLIENT.SSL.CLIENT_HELLO.CIPHERS.HAS_HEXCODE
- CLIENT.SSL.CLIENT_HELLO.CLIENT_VERSION
- CLIENT.SSL.CLIENT_HELLO.IS_RENEGOTIATE
- CLIENT.SSL.CLIENT_HELLO.IS_REUSE
- CLIENT.SSL.CLIENT_HELLO.IS_SCSV
- CLIENT.SSL.CLIENT_HELLO.IS_SESSION_TICKET
- CLIENT.SSL.CLIENT_HELLO.LENGTH
- CLIENT.SSL.CLIENT_HELLO.SNI
- CLIENT.SSL.CLIENT_HELLO.ALPN.HAS_NEXTPROTOCOL (from release 13.0 build 61.x)

For a description of these prefixes, see Advanced policy expressions: parsing SSL.

A parameter `forward` is added to the `add SSL action` command and a new bind point `CLIENTHELLO_REQ` is added to the `bind ssl vserver` command.

Configuration using the CLI

At the command prompt, type:

```
add ssl action <name> -forward <virtual server name>

add ssl policy <name> -rule <expression> -action <string>

bind ssl vserver <vServerName> -policyName <string> -priority <
    positive_integer> -type <type>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

EXAMPLE:

```
add ssl action act1 -forward v2

add ssl policy pol1 -rule client.ssl.client_hello.ciphers.has_hexcode(0
   x002f) -action act1

bind ssl vserver v1 -policyName pol1 -priority 1 -type CLIENTHELLO_REQ
```

Configuration using the GUI

Navigate to **Traffic Management > SSL > Policies**.

Create SSL action:

1. In **SSL Actions**, click **Add**.
2. In **Create SSL Action**, specify a name for the action.
3. In **Forward Action Virtual Server**, select an existing virtual server or add a new virtual server to forward the traffic to.
4. Optionally, set other parameters.
5. Click **Create**.

Create SSL policy:

1. In **SSL Policies**, click **Add**.
2. In **Create SSL Policy**, specify a name for the policy.
3. In **Action**, select the action that you created earlier.
4. In **Expression Editor**, enter the rule to evaluate.
5. Click **Create**.

Create or add a virtual server and bind policy:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Add or select a virtual server.
3. In **Advanced Settings**, click **SSL Policies**.
4. Click in the SSL Policy section.
5. In **Select Policy**, select the policy that you created earlier.
6. In **Policy Binding**, specify a priority for the policy.
7. In **Type**, select **CLIENTHELLO_REQ**.
8. Click **Bind**.
9. Click **Done**.

For the end-to-end configuration for the most popular use cases, see the following topics:

- Configure SSL action to forward client traffic if the appliance does not have a domain specific (SNI) certificate.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- Configure an SSL action to forward client traffic based on the protocol in the ALPN extension of the client hello message.
- Configure SSL action to forward client traffic if a cipher is not supported on the ADC.

SSL action to selectively pick CAs based on SNI for client authentication

You can send only the list of CAs based on SNI (domain) in the client certificate request rather than the list of all the CAs bound to an SSL virtual server. For example, when a client hello is received, only the CA certificates based on the SSL policy expression (for example, SNI) are sent. To send a specific set of certificates, you must create a CA certificates group. Then, bind this group to an SSL action, and bind the action to an SSL policy. If the policy bound to the virtual server receiving client traffic evaluates to true after parsing the client hello, only a specific CA certificates group is sent in the client request certificate.

Earlier, you had to bind CA certificates to an SSL virtual server. With this enhancement, you can simply add CA certificate groups and associate them to an SSL action.

Note: Enable client authentication and SNI on the SSL virtual server. Bind the correct SNI certificates to the virtual server.

Perform the following steps:

1. Add a CA certificate group.
2. Add certificate-key pairs.
3. Bind the certificate-key pairs to this group.
4. Add an SSL action.
5. Add an SSL policy. Specify the action in the policy.
6. Bind the policy to an SSL virtual server. Specify the bind point as CLIENTHELLO_REQ.

Configuration using the CLI

At the command prompt, type the following commands in a sequence:

```
add ssl caCertGroup <caCertGroupName>
add ssl certkey <certkey_name> -cert <cert> -key <key>
bind ssl caCertGroup <caCertGroupName> <certkey_name>
add ssl action <name> -caCertGrpName <string>
add ssl policy <name> -rule <expression> -action <string>
bind ssl vserver <vServerName> -policyName <string> -priority <
   positive_integer> -type CLIENTHELLO_REQ
```

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add ssl cacertGroup ca_cert_group

add ssl certkey ca_certkey1 -cert cacert1 -key cakey1
add ssl certkey ca_certkey2 -cert cacert2 -key cakey2
add ssl certkey snicert -cert snicert -key snikey

bind ssl cacertGroup ca_cert_group ca_certkey1
bind ssl caCertGroup ca_cert_group ca_certkey2
```

```
sh ssl caCertGroup ca_cert_group

CA GROUP NAME:     ca_cert_group
ACTIONS REFERRING: 1

1) CertKey Name: ca_certkey1   CA Certificate   CRLCheck: Optional
   CA_Name Sent
2) CertKey Name: ca_certkey2   CA Certificate   CRLCheck: Optional
   CA_Name Sent
```

```
add ssl action pick_ca_group -cacertGrpName ca_cert_group
```

```
sh ssl action pick_ca_group
1) Name: pick_ca_group

Configuration using the GUI

Create CA certificates group and bind certificates to the group:

1. Navigate to **Traffic Management > SSL > CA Certificates Group**.
2. Click **Add** and specify a name for the group.
3. Click **Create**.
4. Select the **CA certificate group** and then click **Show Bindings**.
5. Click **Bind**.
6. In the **CA Certificate Binding** page, select an existing certificate or click Add to add a new cer-

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

tificate.
7. Click **Select** and then click **Bind**.
8. To bind another certificate, repeat steps 5 through 7.
9. Click **Close**.

Navigate to **Traffic Management > SSL > Policies**.

Create SSL action:

1. In **SSL Actions**, click **Add**.
2. In **Create SSL Action**, specify a name for the action.
3. In **Forward Action Virtual Server**, select an existing virtual server or add a virtual server to forward the traffic to.
4. Optionally, set other parameters.
5. Click **Create**.

Create SSL policy:

1. In **SSL Policies**, click **Add**.
2. In **Create SSL Policy**, specify a name for the policy.
3. In **Action**, select the action created earlier.
4. In **Expression Editor**, enter the rule to evaluate.
5. Click **Create**.

Create or add a virtual server and bind policy:

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Add or select a virtual server.
3. In **Advanced Settings**, click **SSL Policies**.
4. Click in the SSL Policy section.
5. In **Select Policy**, select the policy that you created earlier.
6. In **Policy Binding**, specify a priority for the policy.
7. In **Type**, select **CLIENTHELLO_REQ**.
8. Click **Bind**.
9. Click **Done**.

Unbind a CA certificate group by using the GUI

1. Navigate to **Traffic Management > SSL > CA Certificates Group**.
2. Select a certificate group and click **Show Bindings**.
3. Select the certificate to remove from the group and click **Unbind**.
4. If prompted for confirmation, click **Yes••.
5. Click **Close**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Remove a CA certificate group by using the GUI

1. Navigate to **Traffic Management > SSL > CA Certificates Group**.
2. Select a certificate group and click **Delete**.
3. If prompted for confirmation, click **Yes**.

SSL policy binding

September 14, 2021

You can bind SSL policies globally or to an SSL type virtual server only. Globally bound policies are evaluated after all policies bound to services, virtual servers, or other Citrix ADC bind points are evaluated. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered, and the action associated with it is carried out.

When binding an SSL policy to a virtual server, you must select from one of the following bind points:

- REQUEST (Default bind point. Policy evaluation is done in the HTTP layer after the SSL handshake is completed.)
- INTERCEPT_REQ (This option applies to a Citrix Secure Web Gateway setup. For more information, see SSL policy infrastructure for SSL interception).
- CLIENTHELLO_REQ

Similarly, when unbinding a policy from a virtual server, you must specify the bind point.

If you specify CLIENTHELLO_REQ as the bind point, the policy is evaluated when a client hello message is received. The allowed actions are RESET, FORWARD, and `caCertGrpName`. The reset action terminates the connection. The forward action forwards the request to a load balancing virtual server for processing. The `caCertGrpName` action selectively picks CAs based on SNI for client authentication. For more information about SSL actions, see SSL built-in actions and user-defined actions.

Note: The action caCertGrpName is not supported with the TLS 1.3 protocol.

Bind an SSL policy globally by using the CLI

At the command prompt, type the following command to bind a global SSL policy and verify the configuration:

```
bind ssl global - policyName <string> [- priority <positive_integer>]
show ssl global
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Example:

```
bind ssl global -policyName Policy-SSL-2 -priority 90
Done

sh ssl global

     1) Name: Policy-SSL-2 Priority: 90
     2) Name: Policy-SSL-1 Priority: 100
     Done
```

Bind an SSL policy globally by using the GUI

1. Navigate to **Traffic Management** > **SSL** > **Policies**.
2. In the details pane, click **Global Bindings**.
3. In the **Bind/Unbind SSL Policies to Global** dialog box, click **Insert Policy**.
4. In the **Policy Name** list, select a policy.
5. Optionally, drag the entry to a new position in the policy bank to automatically update the priority level.
6. Click **OK**. A message appears in the status bar, stating that the policy has been bound successfully.

Bind or unbind an SSL policy to a virtual server by using the CLI

At the command prompt, type the following command to bind an SSL policy to a virtual server and verify the configuration:

```
bind ssl vserver <vServerName> -policyName <string> -priority <
   positive_integer> -type <type>

unbind ssl vserver <vServerName> -policyName <string> -priority <
   positive_integer> -type <type>
```

Example:

```
bind ssl vserver v1 -policyName pol1 -priority 1 -type CLIENTHELLO_REQ
```

```
unbind ssl vserver v1 -policyName pol1 -priority 1 -type
   CLIENTHELLO_REQ
```

```
show ssl vserver vs-server

Advanced SSL configuration for VServer vs-server:

DH: DISABLED

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
Ephemeral RSA: ENABLED          Refresh Count: 1000

Session Reuse: ENABLED          Timeout: 120 seconds

Cipher Redirect: DISABLED

SSLv2 Redirect: DISABLED

ClearText Port: 80

Client Auth: DISABLED

SSL Redirect: ENABLED

SSL-REDIRECT Port Rewrite: ENABLED

Non FIPS Ciphers: DISABLED

SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)      Policy Name: ssl-policy-1        Priority: 10

1)      Cipher Name: DEFAULT

            Description: Predefined Cipher Alias

Done
```

Bind an SSL policy to a virtual server by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and open an SSL virtual server.
2. In **Advanced Settings**, select **SSL Policy**. Click in the **SSL policy** section to bind a policy to the virtual server.
3. In the **Policy Binding** page, select an existing policy or add a new policy.
4. Specify priority and type (bind point) for the policy.
5. Select **Bind**.
6. Select **Done**.

SSL policy labels

May 24, 2023

Policy labels are holders for policies. A policy label helps in managing a group of policies, called a policy bank, which can be invoked from another policy. SSL policy labels can be control labels or data

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

labels, depending on the type of policies that are included in the policy label. You can add only data policies in a data policy label and only control policies in a control policy label. To create the policy bank, bind policies to the label and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. At the CLI, you enter two commands to create a policy label and bind policies to the policy label. In the configuration utility, you select options from a dialog box.

Note: Policy labels of type control are not supported with the TLS 1.3 protocol.

Create an SSL policy label and bind policies to the label by using the CLI

At the command prompt, type:

```
add ssl policylabel <labelName> -type ( CONTROL | DATA )

bind ssl policylabel <labelName> <policyName> <priority> [<
   gotoPriorityExpression>] [-invoke (<labelType> <labelName>) ]
```

Example:

```
add ssl policylabel cpl1 -type CONTROL
add ssl policylabel dpl1 -type DATA

add ssl action act1 -clientauth DOCLIENTAUTH
add ssl policy ctrlpol -rule HTTP.REQ.METHOD.EQ("GET") -action act1

add ssl action act2 -clientCert ENABLED -certHeader "X-Client-Cert"
add ssl policy datapol -rule CLIENT.SSL.CLIENT_CERT.EXISTS -action act2

bind ssl policylabel cpl1 ctrlpol 1
bind ssl policylabel dpl1 datapol 1

> sh ssl policylabel
Control policylabels
1)  Label Name: cpl1
    Type: CONTROL
    Number of bound policies: 1
    Number of times invoked: 0

Data policylabels
1)  Label Name: dpl1
    Type: DATA
    Number of bound policies: 1
    Number of times invoked: 0
Done
>
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure an SSL policy label and bind policies to the label by using the GUI

Navigate to **Traffic Management > SSL > Policy Labels**, and configure an SSL policy label.

Selective SSL logging

September 14, 2021

In a large deployment comprising thousands of virtual servers, all SSL-related information is logged. Earlier, filtering the client authentication and SSL handshake successes and failures for a few critical virtual servers was not easy. Perusing through the entire log to get this information was a time-consuming and tedious task because the infrastructure did not offer the control to filter the logs. Now, you can log SSL-related information in `ns.log`, for a specific virtual server or for a group of virtual servers. This information is especially helpful in debugging failures. To log this information, you must add an SSL log profile.

See sample ns.log output for successful client authentication at the end of this page.

Important: Set the syslog log level to DEBUG. At the command prompt, type:

```
set audit syslogParams -logLevel DEBUG
```

SSL log profile

An SSL log profile provides control over logging the following events for a virtual server or a group of virtual servers:

- Client authentication success and failures, or only failures.
- SSL handshake success and failures, or only failures.

By default, all the parameters are disabled.

An SSL log profile can be set on an SSL profile, or on an SSL action. If set to an SSL profile, you can log both client authentication and SSL handshake success and failure information. If set to an SSL action, you can only log client authentication success and failure information because the handshake is complete before the policy is evaluated.

Client authentication and SSL handshake success and failures are logged even if you do not configure an SSL log profile. However, selective logging is possible only if an SSL log profile is used.

> **Note:**

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> SSL log profile is supported in high availability and cluster setups.

Add an SSL log profile by using the CLI

At the command prompt, type:

```
add ssl logprofile <name> [-sslLogClAuth ( ENABLED | DISABLED )] [-
    ssllogClAuthFailures ( ENABLED | DISABLED )] [-sslLogHS ( ENABLED |
    DISABLED )] [-sslLogHSfailures ( ENABLED | DISABLED )]
```

Parameters:

Name:

Name for the SSL log profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the profile is created.

Name is a mandatory argument. Maximum Length: 127

sslLogClAuth:

Log all client authentication events. Includes both success and failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

ssllogClAuthFailures:

Log all client authentication failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sslLogHS:

Log all SSL handshake related events. Includes both success and failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sslLogHSfailures:

Log all SSL handshake related failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> add ssl logprofile ssllog10 -sslLogClAuth ENABLED -sslLogHS ENABLED

 Done

sh ssllogprofile ssllog10

1)      Name: ssllog10

        SSL log ClientAuth [Success/Failures] : ENABLED

        SSL log ClientAuth [Failures] : DISABLED

        SSL log Handshake [Success/Failures] : ENABLED

        SSL log Handshake [Failures] : DISABLED

 Done
```

Add an SSL log profile by using the GUI

Navigate to **System > Profiles > SSL Log Profile** and add a profile.

Modify an SSL log profile by using the CLI

At the command prompt type:

```
set ssl logprofile <name> [-sslLogClAuth ( ENABLED | DISABLED )][-
    ssllogClAuthFailures ( ENABLED | DISABLED )] [-sslLogHS ( ENABLED |
    DISABLED )] [-sslLogHSfailures ( ENABLED | DISABLED )]
```

Example:

```
set ssllogprofile ssllog10 -ssllogClAuth en -ssllogClAuthFailures en -
    ssllogHS en -ssllogHSfailures en

Done

sh ssllogprofile ssllog10

    1)            Name: ssllog10

                    SSL log ClientAuth [Success/Failures] : ENABLED
                    SSL log ClientAuth [Failures] : ENABLED
                    SSL log Handshake [Success/Failures] : ENABLED
                    SSL log Handshake [Failures] : ENABLED
     Done
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Modify an SSL log profile by using the GUI

1. Navigate to **System > Profiles > SSL Log Profile**, select a profile, and click **Edit**.
2. Make changes and click **OK**.

View all the SSL log profiles by using the CLI

At the command prompt, type:

```
sh ssl logprofile
```

Example:

```
sh ssl logprofile

    1)            Name: ssllogp1
                    SSL log ClientAuth [Success/Failures] : ENABLED
                    SSL log ClientAuth [Failures] : ENABLED
                    SSL log Handshake [Success/Failures] : DISABLED
                    SSL log Handshake [Failures] : ENABLED

    2)            Name: ssllogp2
                    SSL log ClientAuth [Success/Failures] : DISABLED
                    SSL log ClientAuth [Failures] : DISABLED
                    SSL log Handshake [Success/Failures] : DISABLED
                    SSL log Handshake [Failures] : DISABLED

    3)            Name: ssllogp3
                    SSL log ClientAuth [Success/Failures] : DISABLED
                    SSL log ClientAuth [Failures] : DISABLED
                    SSL log Handshake [Success/Failures] : DISABLED
                    SSL log Handshake [Failures] : DISABLED

    4)            Name: ssllog10
                    SSL log ClientAuth [Success/Failures] : ENABLED
                    SSL log ClientAuth [Failures] : ENABLED
                    SSL log Handshake [Success/Failures] : ENABLED
                    SSL log Handshake [Failures] : ENABLED
Done
```

View all the SSL log profiles by using the GUI

Navigate to **System > Profiles > SSL Log Profile**. All the profiles are listed.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Attach an SSL log profile to an SSL profile

You can attach (set) an SSL log profile on an SSL profile when you are creating an SSL profile, or later by editing the SSL profile. You can log both client authentication and handshake successes and failures.

> **Important:**
>
> The default SSL profile must be enabled before you can attach an SSL log profile.

Attach an SSL log profile on an SSL profile by using the CLI

At the command prompt, type:

```
set ssl profile <name> [-ssllogProfile <string>]
```

Example:

```
set ssl profile fron_1 -ssllogProfile ssllog10
```

Attach an SSL log profile to an SSL profile by using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. Click **Edit** and in **SSL Log Profile**, specify a profile.

Attach an SSL log profile to an SSL action

You can set an SSL log profile only while creating an SSL action. You cannot modify an SSL action to set the log profile. Associate the action to a policy. You can only log client authentication successes and failures.

Attach an SSL log profile to an SSL action by using the CLI

At the command prompt, type:

```
add ssl action <name> -clientAuth ( DOCLIENTAUTH | NOCLIENTAUTH ) -
    ssllogProfile <string>
```

Example:

```
> add ssl action act1 -clientAuth DoCLIENTAUTH -ssllogProfile ssllog10

Done

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
> sh ssl action act1

    1)            Name: act1
                    Type: Client Authentication (DOCLIENTAUTH)
                    Hits: 0
                    Undef Hits: 0
                    Action Reference Count: 0
                    SSLlogProfile: ssllog10
Done
```

Attach an SSL log profile to an SSL action by using the GUI

1. Navigate to **Traffic Management > SSL > Policies** and click **SSL Actions**.
2. Click **Add**.
3. In Client Authentication, select **ENABLED**.
4. In SSL Log Profile, select a profile from the list, or click "+"to create a profile.
5. Click **Create**.

Sample output from the log file

The following is a sample log output from `ns.log` for successful client authentication.

```

Support for DTLS protocol

January 31, 2022

> **Notes:**
>
> - DTLSv1.0 protocol is supported on Citrix ADC MPX/SDX (N2 and N3 based), VPX, and MPX 14000 FIPS appliances. It is not supported on external HSMs.
> - DTLS 1.0 protocol is supported on Citrix ADC appliances containing Intel Coleto SSL chips (from release 12.1 build 50.x).
> - DTLSv1.2 protocol is supported on the front-end of Citrix ADC VPX appliances (from release 13.0 build 47.x).
> - DTLS 1.2 protocol is supported on the front-end of Citrix ADC appliances containing Intel Coleto SSL chips (from release 13.0 build 52.x). For more information about the platforms containing Intel Coleto SSL chips, see Support for Intel Coleto SSL chip based platforms.
> - Service groups of type DTLS are not supported.
> - DTLSv1.2 protocol is supported on the front-end of Citrix ADC MPX (N3 based) appliances (from release 13.0 build 58.x).
> - For information about Enlightened Data Transport (EDT) support for Citrix Gateway, see HDX enlightened data transport support.
> - There are changes made to the DTLS profile from release 13.0 build 79.x. For more information, see DTLS profile.
> - From release 13.0 build 82.x, a new parameter `maxBadmacIgnorecount` is introduced in the DTLS profile to ignore bad MAC records received in a DTLS session. For more information, see DTLS profile.
> - For information about the platforms and builds supported, see Citrix ADC MPX hardware-software compatibility matrix

The SSL and TLS protocols have traditionally been used to secure streaming traffic. Both of these protocols are based on TCP, which is slow. Also, TLS cannot handle lost or reordered packets.

UDP is the preferred protocol for audio and video applications, such as Lync, Skype, iTunes, YouTube, training videos, and flash. However, UDP is not secure or reliable. The DTLS protocol is designed to secure data over UDP and is used for applications such as media streaming, VOIP, and online gaming for communication. In DTLS, each handshake message is assigned a specific sequence number within that handshake. When a peer receives a handshake message, it can quickly determine whether that

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

message is the next one expected. If it is, the peer processes the message. If not, the message is queued for handling after all the previous messages have been received.

Create a DTLS virtual server and a service of type UDP. By default, a DTLS profile (nsdtls_default_profile) is bound to the virtual server. Optionally, you can create and bind a user-defined DTLS profile to the virtual server.

Note: RC4 ciphers are not supported on a DTLS virtual server.

DTLS configuration

You can use the command line (CLI) or the configuration utility (GUI) to configure DTLS on your ADC appliance.

Note: From release 13.0 build 47.x, the DTLS 1.2 protocol is supported on the front end of a Citrix ADC VPX appliance. While configuring a DTLSv1.2 virtual server, specify DTLS12. Default is DTLS1.

At the command prompt, type:

```
set ssl vserver DTLS [-dtls1 ( ENABLED | DISABLED )] [-dtls12 (
ENABLED | DISABLED )]
```

Create a DTLS configuration by using the CLI

At the command prompt, type:

```
1 add lb vserver <vserver_name> DTLS <IPAddress>  <port>
2 add service  <service_name>  <IPAddress> UDP 443
3 bind lb vserver  <vserver_name>  <udp_service_name>
```

The following steps are optional:

```
1 add dtlsProfile dtls-profile -maxretryTime <positive_integer>
2 set ssl vserver <vserver_name> -dtlsProfileName <dtls_profile_name>
```

Create a DTLS configuration by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Create a virtual server of type DTLS, and bind a UDP service to the virtual server.
3. A default DTLS profile is bound to the DTLS virtual server. To bind a different profile, in SSL Parameters, select a different DTLS profile. To create a profile, click the plus (+) next to DTLS Profile.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Support for SNI on a DTLS virtual server

For information about SNI, see Configure an SNI virtual server for secure hosting of multiple sites.

Configure SNI on a DTLS virtual server by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName> -SNIEnable ENABLED
bind ssl vserver <vServerName> -certkeyName <string> -SNICert
show ssl vserver <vServerName>
```

Example:

```
set ssl vserver v1 -sniEnable ENABLED
bind ssl vserver  v1 -certkeyName san2 -sniCert
bind ssl vserver  v1 -certkeyName san13  – sniCert
bind ssl vserver  v1 -certkeyName san17  – sniCert
```

```
sh ssl vserver v1

Advanced SSL configuration for VServer v1:
DH: DISABLED
DH Private-Key Exponent Size Limit: DISABLED
Ephemeral RSA: ENABLED
Refresh Count: 0
Session Reuse: ENABLED
Timeout: 1800 seconds
Cipher Redirect: DISABLED

ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: ENABLED
OCSP Stapling: DISABLED
HSTS: DISABLED
HSTS IncludeSubDomains: NO
HSTS Max-Age: 0
DTLSv1: ENABLED
Send Close-Notify: YES
Strict Sig-Digest Check: DISABLED
Zero RTT Early Data: DISABLED
DHE Key Exchange With PSK: NO
Tickets Per Authentication Context: 1

DTLS profile name: nsdtls_default_profile

ECC Curve: P_256, P_384, P_224, P_521

1) CertKey Name: ca
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
33 CA Certificate  OCSPCheck: OptionalCA_Name Sent
34 2) CertKey Name: san2 Server Certificate for SNI
35 3) CertKey Name: san17 Server Certificate for SNI
36 4) CertKey Name: san13 Server Certificate for SNI
37
38
39 1) Cipher Name: DEFAULT
40 Description: Default cipher list with encryption strength >= 128bit
41 Done
```

Configure SNI on a DTLS virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a DTLS virtual server and, in Certificates, click **Server Certificate**.
3. Add a certificate or select a certificate from the list and select **Server Certificate for SNI**.
4. In **Advanced Settings**, click **SSL Parameters**.
5. Select **SNI Enable**.

Features not supported by a DTLS virtual server

The following options cannot be enabled on a DTLS virtual server:

- SSLv2
- SSLv3
- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL

Parameters not used by a DTLS virtual server

A DTLS virtual server ignores the following SSL parameters, even if set:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Configure renegotiation on a DTLS service

Non-secure renegotiation is supported on a DTLS service. You can use the CLI or the GUI to configure this setting.

Configure renegotiation on a DTLS service by using the CLI

At the command prompt, type:

```
set ssl parameter -denysslreneg NONSECURE
```

Example:

```
set ssl parameter -denysslreneg NONSECURE

sh ssl parameter
Advanced SSL Parameters
-----------------------
SSL quantum size                                  : 8 KB
Max CRL memory size                               : 256 MB
Strict CA checks                                  : NO
Encryption trigger timeout                        : 100 ms
Send Close-Notify                                 : YES
Encryption trigger packet count                   : 45
Deny SSL Renegotiation                            : NONSECURE
Subject/Issuer Name Insertion Format              : Unicode
OCSP cache size                                   : 10 MB
Push flag                                         : 0x0 (Auto)
Strict Host Header check for SNI enabled SSL sessions : NO
PUSH encryption trigger timeout                   : 1 ms
Crypto Device Disable Limit                       : 0
Global undef action for control policies          : CLIENTAUTH

```

Configure renegotiation on a DTLS service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

2. Select a DTLS service and click **Edit**.
3. Navigate to **SSL** > **Advanced Settings**.
4. Select **Deny SSL Renegotiation**.

Features not supported by a DTLS service

The following options cannot be enabled on a DTLS service:

- SSLv2
- SSLv3
- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL
- SNI
- Secure renegotiation

Parameters not used by a DTLS service

A DTLS service ignores the following SSL parameters, even if set:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

> **Note:**
>
> SSL session reuse handshake fails on a DTLS service because session reuse is not currently supported on DTLS services.
>
> **Workaround:** Manually disable session reuse on a DTLS service. At the CLI, type:
>
> ```
> set ssl service <dtls-service-name> -sessReuse DISABLED
> ```

DTLS profile

A DTLS profile with the default settings is automatically bound to a DTLS virtual server. However, you can create a DTLS profile with specific settings to suit your requirement.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Use a DTLS profile with a DTLS virtual server or a VPN DTLS virtual server. You cannot use an SSL profile with a DTLS virtual server.

> **Note:**
>
> Change the maximum record size setting in the DTLS profile based on the changes in MTU and packet size. For example, the default max record size of 1459 bytes is calculated based on an IPv4 address header size. With IPv6 records, the header size is larger and therefore the maximum record size must be reduced to meet the following criteria.

```
max record size + UDP header(8bytes)+ IP header size < MTU
```

Example:

```
Default DTLS profile
    1) Name: nsdtls_default_profile
    PMTU Discovery: DISABLED
    Max Record Size: 1459 bytes
    Max Retry Time: 3 sec
    Hello Verify Request: ENABLED
    Terminate Session: DISABLED
    Max Packet Count: 120 bytes

Custom DTLS profile
    1) Name: ns_dtls_profile_ipv6_1
    PMTU Discovery: DISABLED
    Max Record Size: 1450 bytes
    Max Retry Time: 3 sec
    Hello Verify Request: ENABLED
    Terminate Session: DISABLED
    Max Packet Count: 120 bytes
```

Create a DTLS profile by using the CLI

> **Notes:**
>
> From release 13.0 build 79.x, the changes to the DTLS profile are as follows:
>
> - The `helloverifyrequest` parameter is enabled by default. Enabling this parameter helps mitigate the risk of an attacker or bots overwhelming the network throughput, potentially leading to outbound bandwidth exhaustion. That is, it helps mitigate the DTLS DDoS amplification attack.
> - The `maxHoldQlen` parameter is added. This parameter defines the number of datagrams that can be queued at the DTLS layer for processing. A high value of the `maxHoldQlen` parameter can cause memory buildup at the DTLS layer if UDP multiplexing is transmitting high UDP traffic. Therefore, configuring a lower value is recommended. Minimum value is 32, maximum value is 65535, and default value is 32.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

> From release 13.0 build 82.x, a new parameter `maxBadmacIgnorecount` is introduced in the DTLS profile to ignore bad MAC records received in a DTLS session. Using this parameter, bad records up to the value set in the parameter are ignored. The appliance terminates the session only after the limit is reached and sends an alert.
> This parameter setting is effective only when the `terminateSession` parameter is enabled.

```
ssl dtlsProfile <name> -maxRetryTime <positive_integer> -
    helloVerifyRequest ( ENABLED | DISABLED ) -terminateSession (ENABLED
     | DISABLED ) -maxHoldQLen <positive_integer> -maxBadmacIgnorecount
    <positive_integer>

helloVerifyRequest
               Send a Hello Verify request to validate the client.
               Possible values: ENABLED, DISABLED
               Default value: ENABLED

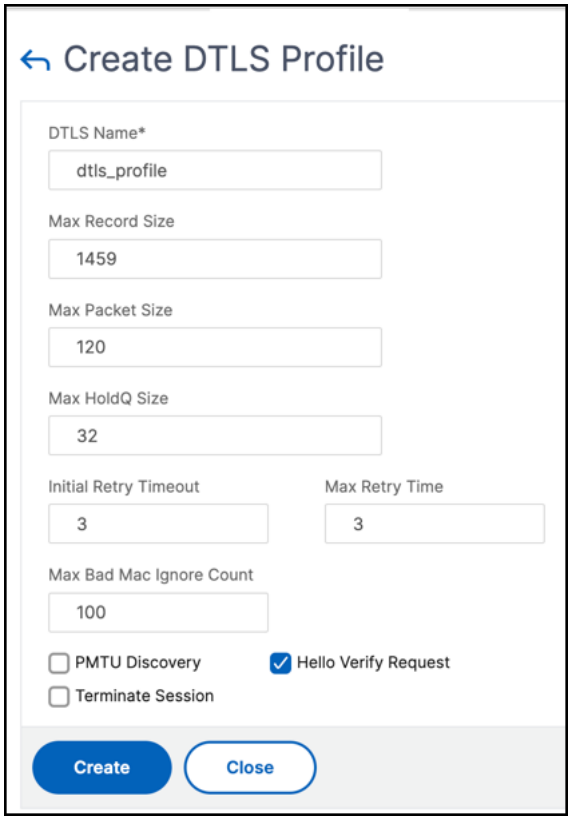
terminateSession
               Terminate the session if the message authentication code
                   (MAC)
               of the client and server do not match.
               Possible values: ENABLED, DISABLED
               Default value: DISABLED

maxHoldQLen
               Maximum number of datagrams that can be queued at DTLS
                   layer for
               processing
               Default value: 32
               Minimum value: 32
               Maximum value: 65535

maxBadmacIgnorecount
               Maximum number of bad MAC errors to ignore for a
                   connection prior disconnect. Disabling parameter
                   terminateSession
terminates session immediately when bad MAC is detected in the
    connection.
               Default value: 100
               Minimum value: 1
               Maximum value: 65535
```

Example:

```
> add ssl dtlsprofile dtls_profile -maxRetryTime 4 -helloVerifyRequest
    ENABLED -terminateSession ENABLED -maxHoldQLen 40 -
    maxBadmacIgnorecount 150
 Done
> sh dtlsprofile dtls_profile
1)  Name: dtls_profile
    PMTU Discovery: DISABLED
    Max Record Size: 1459 bytes
    Max Retry Time: 4 sec
```



© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
    Hello Verify Request: ENABLED
    Terminate Session: ENABLED
    Max Packet Count: 120 bytes
    Max HoldQ Size: 40 datagrams
    Max bad-MAC Ignore Count: 150

Done
```

Create a DTLS profile by using the GUI

1. Navigate to **System > Profiles > DTLS Profiles** and click **Add**.
2. In the **Create DTLS Profile** page, type values for the different parameters.

3. Click **Create**.

Example for an end-to-end DTLS configuration

```
enable ns feature SSL LB

add server s1 198.51.100.2

en ns mode usnip

```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
add service svc_dtls s1 DTLS 443

add lb vserver v1 DTLS 10.102.59.244 443

bind ssl vserver v1 -ciphername ALL

add ssl certkey servercert -cert servercert_aia_valid.pem -key
   serverkey_aia.pem

bind ssl vserver v1 -certkeyname servercert

bind lb vserver lb1 svc_dtls

sh lb vserver v1

DTLS support for IPv6 address

DTLS is supported with IPv6 addresses also. However, to use DTLS with IPv6 addresses the maximum record size must be adjusted in the DTLS profile.

If the default value is used for the maximum record size, the initial DTLS connection might fail. Adjust the maximum record size using a DTLS profile.

DTLS cipher support

By default, a DTLS cipher group is bound when you create a DTLS virtual server or service. DEFAULT_DTLS contains the ciphers that a front-end DTLS entity supports. This group is bound by default when you create a DTLS virtual server. DEFAULT_DTLS_BACKEND contains the ciphers that are supported to a back-end DTLS entity. This group is bound by default to a DTLS back-end service. DTLS_FIPS contains the ciphers that are supported on the Citrix ADC FIPS platform. This group is bound by default to a DTLS virtual server or service created on a FIPS platform.

DTLS cipher support on Citrix ADC VPX, MPX/SDX (N2 and N3 based) appliances

How to read the tables:

Unless a build number is specified, a cipher suite is supported for all builds in a release.

Example:

- **10.5, 11.0, 11.1, 12.0, 12.1, 13.0**: All builds of 10.5, 11.0, 11.1, 12.0, 12.1, 13.0 releases.
- **-NA-**: not applicable.

          HexCode=0x000a
```

DTLS cipher support on the Citrix ADC MPX 14000 FIPS platform

Note: Enlightened Data Support (EDT) is supported on the FIPS platform if the following conditions are met:

- UDT MSS value set on StoreFront is 900.
- Windows client version is 4.12 or later.
- DTLS enabled VDA version is 7.17 or later.
- Non-DTLS VDA version is 7.15 LTSR CU3 or later.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

How to read the tables:

Unless a build number is specified, a cipher suite is supported for all builds in a release.

Example:

- **10.5, 11.0, 11.1, 12.0, 12.1, 13.0**: All builds of 10.5, 11.0, 11.1, 12.0, 12.1, 13.0 releases.
- **-NA-**: not applicable.

Cipher suite Name	Hex Code	Wireshark Cipher suite Name	Builds Supported (front end)	Builds Supported (back end)
TLS1-AES-256-CBC-SHA	0x0035	TLS_RSA_WITH_AES_256_CBC_SHA	12.0, 12.1–49.x, 13.0	12.0, 12.1–49.x, 13.0
TLS1-AES-128-CBC-SHA	0x002f	TLS_RSA_WITH_AES_128_CBC_SHA	12.0, 12.1–49.x, 13.0	12.0, 12.1–49.x, 13.0
SSL3-DES-CBC-SHA	0x0009	TLS_RSA_WITH_DES_CBC_SHA	12.0, 12.1–49.x, 13.0	-NA-
SSL3-DES-CBC3-SHA	0x000a	TLS_RSA_WITH_3DES_EDE_CBC_SHA	12.0, 12.1–49.x, 13.0	12.0, 12.1–49.x, 13.0
SSL3-EDH-RSA-DES-CBC3-SHA	0x0016	TLS_DHE_RSA_WITH_3DES_EDE_CBC_S	12.0, 12.1–49.x, 13.0	-NA-
SSL3-EDH-RSA-DES-CBC-SHA	0x0015	TLS_DHE_RSA_WITH_DES_CBC_SHA	12.0, 12.1–49.x, 13.0	-NA-
TLS1-ECDHE-RSA-AES256-SHA	0xc014	TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	12.1–49.x, 13.0	12.1–49.x, 13.0
TLS1-ECDHE-RSA-AES128-SHA	0xc013	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	12.1–49.x, 13.0	12.1–49.x, 13.0
TLS1-ECDHE-RSA-DES-CBC3-SHA	0xc012	TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA	12.1–49.x, 13.0	-NA-
TLS1-DHE-RSA-AES-128-CBC-SHA	0x0033	TLS_DHE_RSA_WITH_AES_128_CBC_SHA	12.1–49.x, 13.0	12.1–49.x, 13.0
TLS1-DHE-RSA-AES-256-CBC-SHA	0x0039	TLS_DHE_RSA_WITH_AES_256_CBC_SHA	12.1–49.x, 13.0	12.1–49.x, 13.0

To view the list of default ciphers supported on a Citrix ADC FIPS appliance, at the command prompt, type:

```
show ssl cipher DTLS_FIPS
1)    Cipher Name: TLS1-AES-256-CBC-SHA    Priority : 1
     Description: SSLv3 Kx=RSA      Au=RSA  Enc=AES(256)  Mac=SHA1
        HexCode=0x0035
```

```
2)    Cipher Name: TLS1-AES-128-CBC-SHA    Priority : 2
     Description: SSLv3 Kx=RSA      Au=RSA  Enc=AES(128)  Mac=SHA1
        HexCode=0x002f
3)    Cipher Name: TLS1-ECDHE-RSA-AES256-SHA    Priority : 3
     Description: SSLv3 Kx=ECC-DHE  Au=RSA  Enc=AES(256)  Mac=SHA1
        HexCode=0xc014
4)    Cipher Name: TLS1-ECDHE-RSA-AES128-SHA    Priority : 4
     Description: SSLv3 Kx=ECC-DHE  Au=RSA  Enc=AES(128)  Mac=SHA1
        HexCode=0xc013
5)    Cipher Name: TLS1-ECDHE-RSA-DES-CBC3-SHA  Priority : 5
     Description: SSLv3 Kx=ECC-DHE  Au=RSA  Enc=3DES(168) Mac=SHA1
        HexCode=0xc012
6)    Cipher Name: SSL3-DES-CBC3-SHA    Priority : 6
     Description: SSLv3 Kx=RSA      Au=RSA  Enc=3DES(168) Mac=SHA1
        HexCode=0x000a
```

DTLSv1.2 cipher support on the front-end VPX appliances, MPX/SDX (Coleto and N3 based) appliances

The following table lists the additional ciphers supported for the DTLSv1.2 protocol.

Cipher suite Name	Hex Code	Wireshark Cipher suite Name	Builds Supported (VPX front end)	Builds Supported (Coleto based)	Builds Supported (N3 based)
TLS1.2-AES256-GCM-SHA384	0x009d	TLS_RSA_WITH_AES_256_GCM_SHA384	13.0–52.x	13.0–52.x	13.0–58.x
TLS1.2-AES128-GCM-SHA256	0x009c	TLS_RSA_WITH_AES_128_GCM_SHA256	13.0–52.x	13.0–52.x	13.0–58.x
TLS1.2-ECDHE-RSA-AES256-GCM-SHA384	0xc030	TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	13.0–52.x	13.0–52.x	13.0–58.x
TLS1.2-ECDHE-RSA-AES128-GCM-SHA256	0xc02f	TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	13.0–52.x	13.0–52.x	13.0–58.x
TLS1.2-DHE-RSA-AES256-GCM-SHA384	0x009f	TLS_DHE_RSA_WITH_AES_256_GCM_SHA384	13.0–52.x	13.0–52.x	13.0–58.x

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Cipher suite Name	Hex Code	Wireshark Cipher suite Name	Builds Supported (VPX front end)	Builds Supported (Coleto based)	Builds Supported (N3 based)
TLS1.2-DHE-RSA-AES128-GCM-SHA256	0x009e	TLS_DHE_RSA_WITH_AES_128_GCM_SHA256	13.0–58.x	13.0–52.x	13.0–58.x
TLS1.2-AES-256-SHA256	0x003d	TLS_RSA_WITH_AES_256_CBC_SHA256	13.0–58.x	13.0–52.x	13.0–58.x
TLS1.2-AES-128-SHA256	0x003c	TLS_RSA_WITH_AES_128_CBC_SHA256	13.0–58.x	13.0–52.x	13.0–58.x
TLS1.2-ECDHE-RSA-AES-256-SHA384	0xc028	TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	13.0–58.x	13.0–52.x	13.0–58.x
TLS1.2-ECDHE-RSA-AES-128-SHA256	0xc027	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	13.0–58.x	13.0–52.x	13.0–58.x
TLS1.2-DHE-RSA-AES-256-SHA256	0x006b	TLS_DHE_RSA_WITH_AES_256_CBC_SHA256	13.0–58.x	13.0–52.x	13.0–58.x
TLS1.2-DHE-RSA-AES-128-SHA256	0x0067	TLS_DHE_RSA_WITH_AES_128_CBC_SHA256	13.0–58.x	13.0–52.x	13.0–58.x

Support for Intel Coleto SSL chip based platforms

February 17, 2023

The following appliances ship with Intel Coleto chips:

- MPX 5900
- MPX/SDX 8900
- MPX/SDX 15000
- MPX/SDX 15000-50G
- MPX/SDX 26000
- MPX/SDX 26000-50S

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

- MPX/SDX 26000-100G

Use the ‘show hardware’command to identify whether your appliance has Coleto (COL) chips.

```
> sh hardware

    Platform: NSMPX-8900 8*CPU+4*F1X+6*E1K+1*E1K+1*COL 8955 30010
    Manufactured on: 10/18/2016
    CPU: 2100MHZ
    Host Id: 0
    Serial no: CRAC5CR8UA
    Encoded serial no: CRAC5CR8UA
 Done
```

Note: Secure renegotiation is supported on the back end for these platforms.

Limitations:

- DH 512 cipher is not supported.
- SSLv3 protocol is not supported.
- Hardware security module (HSM) is not supported.
- GnuTLS is not supported.
- ECDSA certificates with ECC curves P_224 and P521 are not supported (Not supported on platforms with Cavium chips also.)
- DNSSEC offload is not supported.

View the SSL chip utilization on Citrix ADC MPX platforms

From release 13.0 build 47.x, you can view the SSL chip utilization on MPX platforms that ship with Intel Coleto chips. This feature is not supported on the SDX platform and on an MPX cluster.

At the command prompt, type:

```
> stat ssl

SSL Summary

# SSL cards present                              4

# SSL cards UP                                   4

SSL engine status                                1

SSL sessions (Rate)                            0

```

Support for nShield Connect hardware security module (HSM)

September 14, 2021

A non-FIPS Citrix ADC appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as the HSM. Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted by using special FIPS approved ciphers.

Only the Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX appliances, or on the SDX and VPX appliances. This limitation is addressed by supporting a nShield Connect external HSM on all Citrix ADC MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 FIPS appliances.

nShield® Connect is an external FIPS-certified network-attached HSM. With an nShield HSM, the keys are securely stored as application key tokens on a remote file server (RFS) and can be reconstituted inside the nShield HSM only.

If you are already using a nShield HSM, you can now use a Citrix ADC to optimize, secure, and control the delivery of all enterprise and cloud services.

Note:

- nShield HSMs comply with FIPS 140-2 Level 3 specifications, while the MPX FIPS appliances comply with level 2 specifications.
- You cannot decrypt the trace while using the nShield HSM. Only the `hardserver` can read the response from the HSM to the Citrix ADC appliance, because it is encrypted.

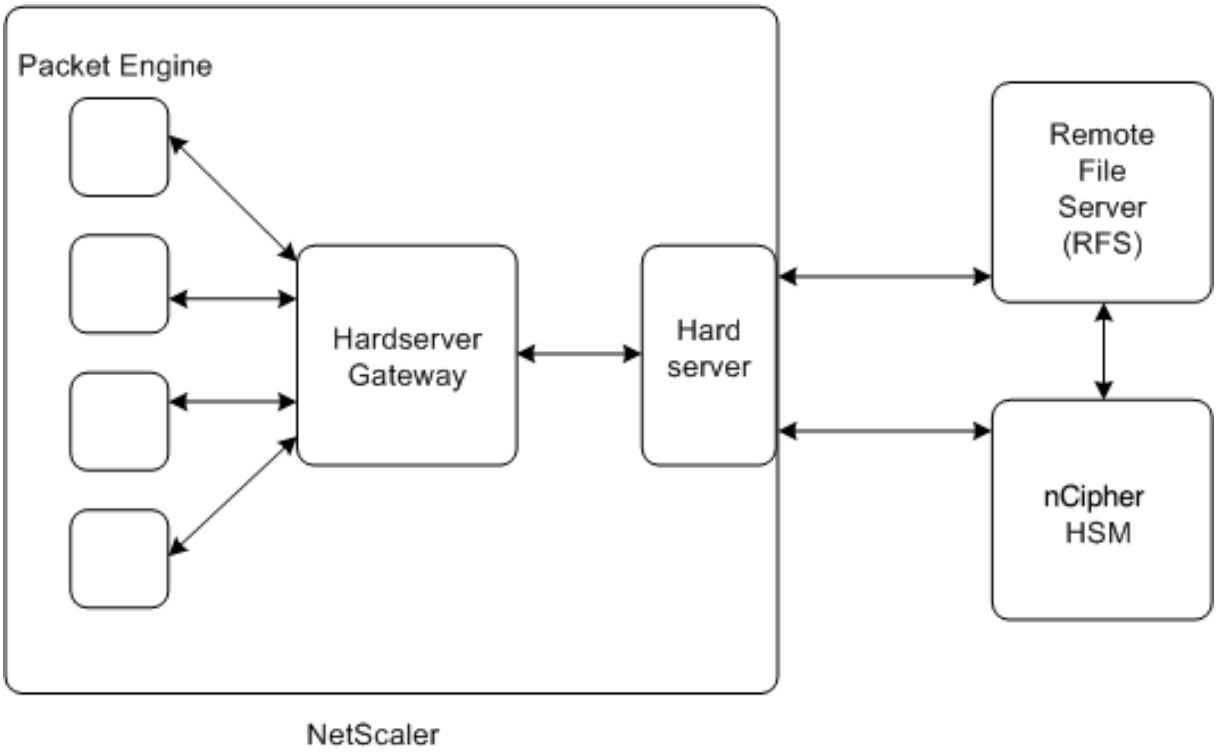
Supported versions matrix

Citrix ADC Version	nShield Client Version	`Hardserver` Version	nShield Firmware Version
10.5e, 11.0, 11.1, 12.0, 12.1	11.70, 11.72	2.71.2	2.50.16, 2.51.10

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Architecture overview

September 14, 2021



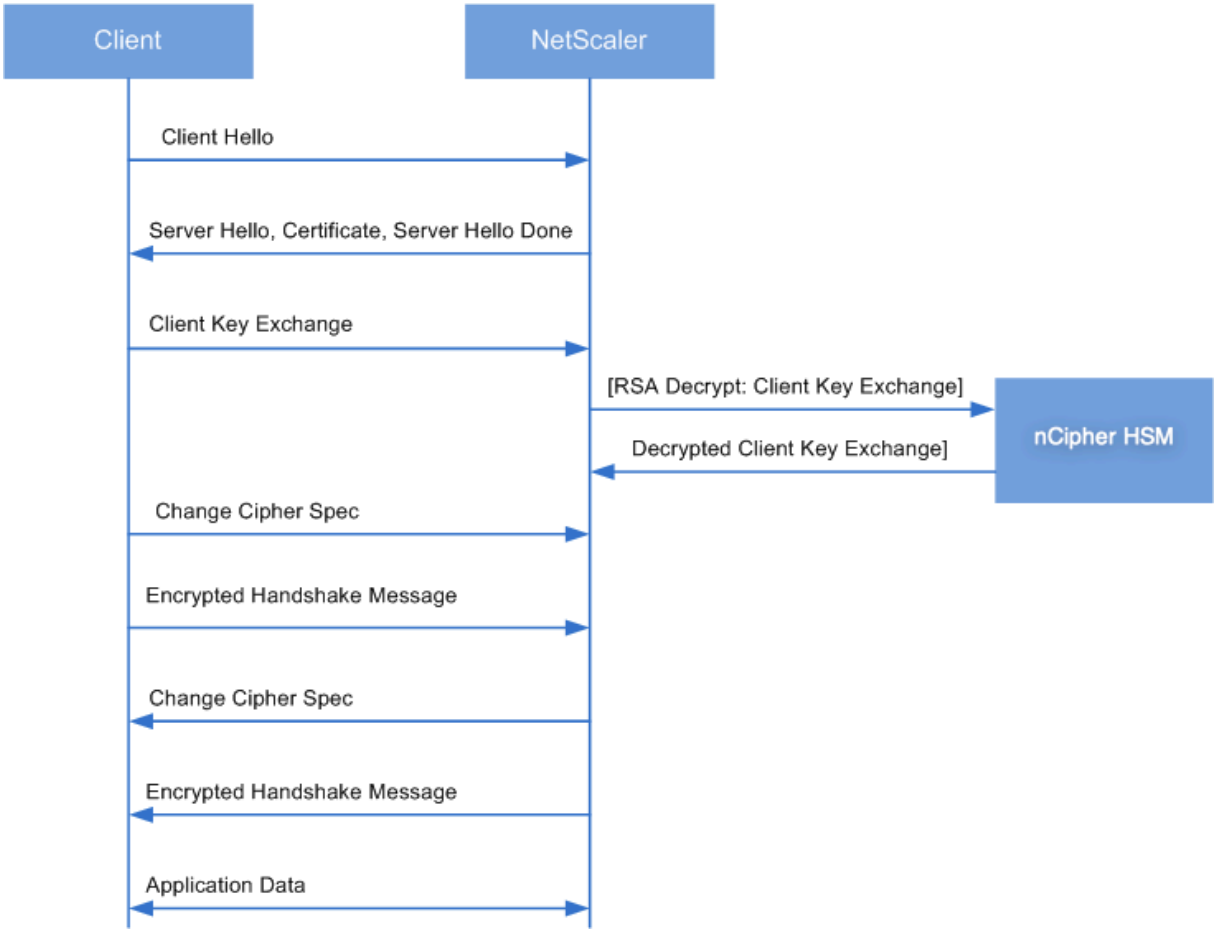
The three entities that are part of a Citrix ADC-Entrust deployment are an Entrust nShield Connect module, a remote file server (RFS), and a Citrix ADC.

The Entrust nShield Connect is a network-attached hardware security module. The RFS is used to configure the HSM and to store the encrypted key files.

`Hardserver`, a proprietary daemon provided by Entrust, is used for communication between the client (ADC), the Entrust HSM, and the RFS. It uses the IMPATH secure communication protocol. A gateway daemon, called the `Hardserver Gateway`, is used to communicate between the Citrix ADC packet engine and the `Hardserver`.

Note: The terms Entrust nShield Connect, Entrust HSM, and HSM are used interchangeably in this documentation.

The following figure illustrates the interaction between the different components.



In a typical deployment, the RFS is used to securely store keys generated by the HSM. After the keys are generated, you can securely transfer them to the ADC and then use the GUI or command line to load the keys to the HSM. A virtual server on the ADC uses Entrust to decrypt the client key exchange to complete the SSL handshake. Thereafter, all the SSL operations are performed on the ADC.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Note: The terms keys and application key tokens are used interchangeably in this documentation.

The following figure illustrates the packet flow in the SSL handshake with the Entrust HSM.

Figure 1. SSL Handshake Packets Flow Diagram with Citrix ADC Using Entrust HSM

Note: The communication between the ADC and the HSM uses an Entrust proprietary communication protocol, called IMPATH.

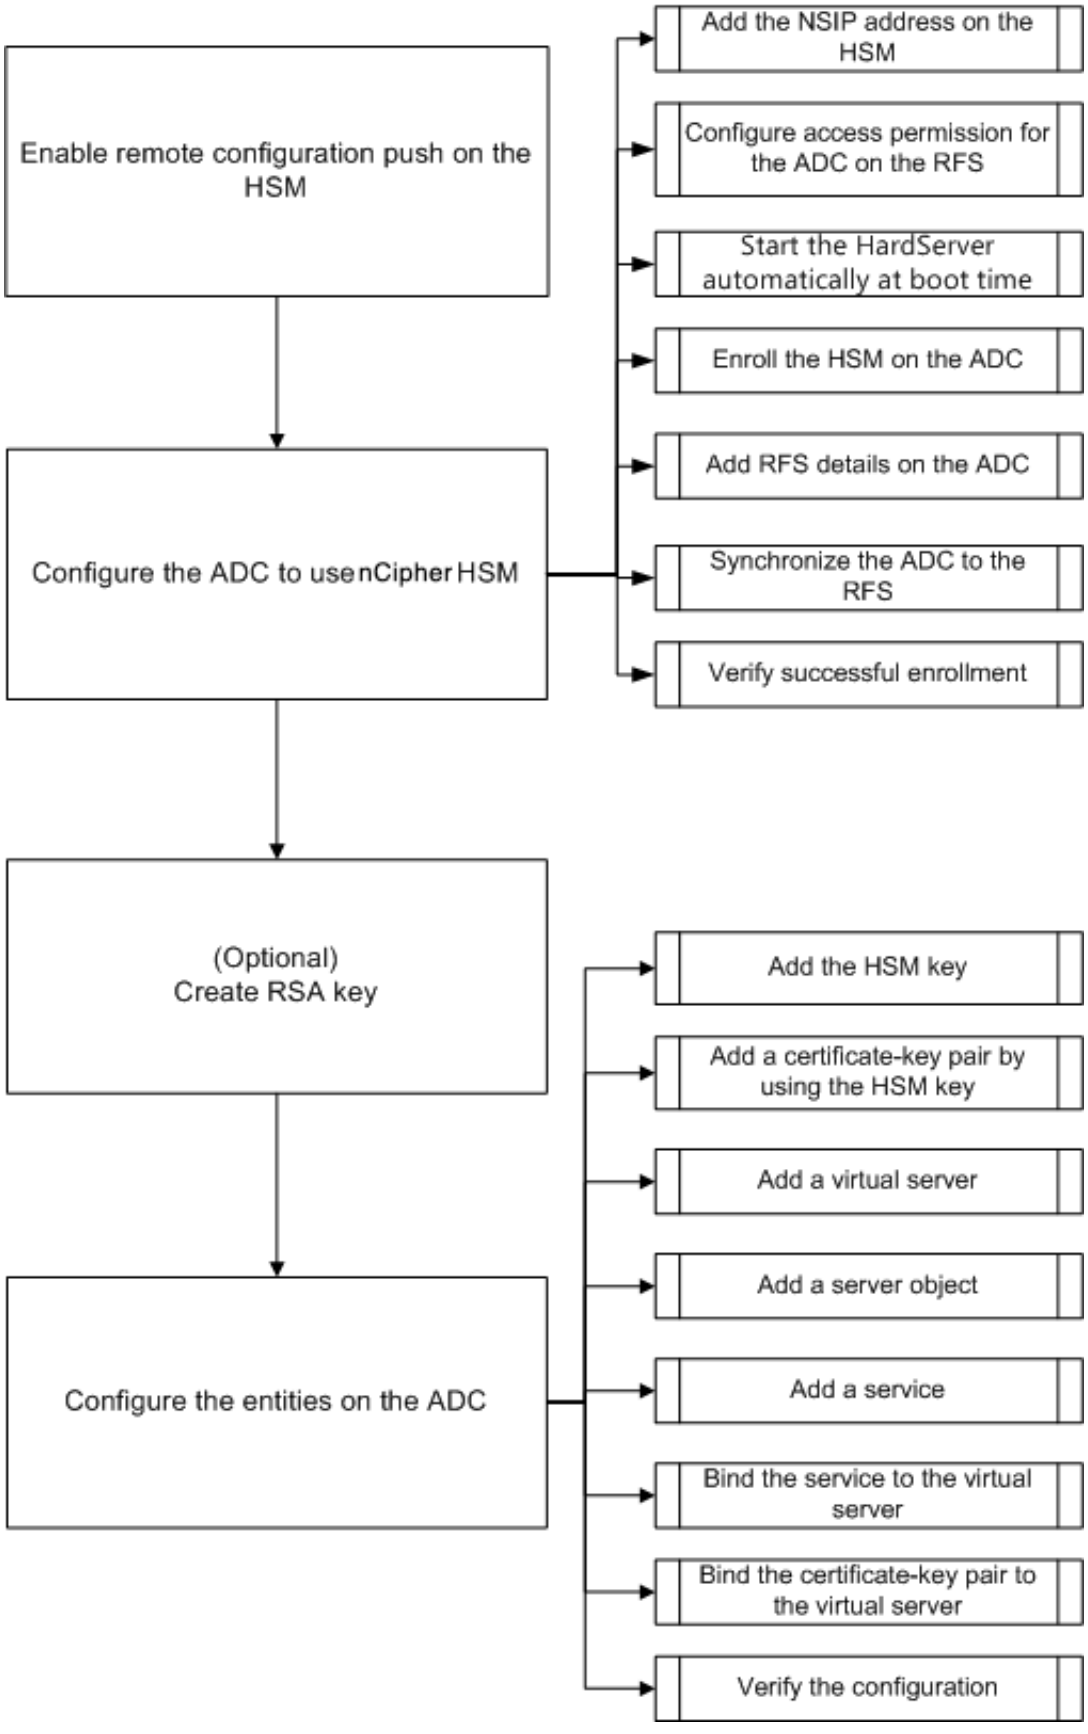
Prerequisites

September 14, 2021

Before you can use an Entrust nShield Connect with a Citrix ADC, make sure that the following prerequisites are met:

- A Entrust nShield Connect device is installed in the network, ready to use, and accessible to the Citrix ADC. That is, the NSIP address is added as an authorized client on the HSM.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.



- A usable Security World exists. Security World is a unique key management architecture used by the Entrust nShield line of HSMs. It protects and manages keys as application key tokens, enabling unlimited key capacity, and automatic key backup and recovery. For more information about creating a Security World, see the nShield Connect Quick Start Guide from Entrust. You can also find the guide in the CD provided with the Entrust HSM module at CipherTools-linux-dev-xx.xx.xx/document/nShield_Connect_Quick_Start_Guide.pdf.
  Note: `Softcard` or token/OCS protected keys are currently not supported on the Citrix ADC.
- Licenses are available to support the number of clients that are connected to the Entrust HSM. The ADC and remote file server (RFS) are clients of the HSM.
- An RFS is installed in the network and is accessible to the Citrix ADC.
- The Entrust nShield Connect device, the RFS, and the Citrix ADC can initiate connections with each other through port 9004.
- You are using NetScaler release 10.5 build 52.1115.e or later.
- The Citrix ADC appliance does not contain a FIPS Cavium card.
  Important: Entrust HSM is not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

Configure the ADC-Entrust integration

September 14, 2021

The following flowchart depicts the tasks that you need to perform to use Entrust HSM with a Citrix ADC:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

As shown in the preceding flowchart, you perform the following tasks:

1. Enable remote configuration push, on the HSM.
2. Configure the ADC to use the Entrust HSM.
    - Add the NSIP address on the HSM.
    - Configure access permission for the ADC on the RFS.
    - Configure automatic start of the `Hardserver` at boot time.
    - Enroll the HSM on the ADC.
    - Add RFS details on the ADC.
    - Synchronize the ADC to the RFS.
    - Verify that Entrust HSM is successfully enrolled on the ADC.
3. (Optional) Create an HSM RSA key.
4. Configure the entities on the Citrix ADC.
    - Add the HSM key.
    - Add a certificate-key pair by using the HSM key.
    - Add a virtual server.
    - Add a server object.
    - Add a service.
    - Bind the service to the virtual server.
    - Bind the certificate-key pair to the virtual server.
    - Verify the configuration.

Configure the Entrust HSM

Specify the IP address of the RFS on the Entrust HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Entrust HSM to perform the following procedure.

Specify the IP address of a remote computer on the Entrust HSM

1. Navigate to **System Configuration > Config file options > Allow auto push**.
2. Select **ON**, and specify the IP address of the computer (RFS) from which to accept the configuration.

Enable pushing the remote configuration on the HSM

Specify the IP address of the RFS on the Entrust HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Entrust HSM to perform the following procedure.

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

Specify the IP address of a remote computer on the Entrust HSM

1. Navigate to **System Configuration > Config file options > Allow auto push**.
2. Select **ON**, and specify the IP address of the computer (RFS) from which to accept the configuration.

Configure the ADC to use the Entrust HSM

Sample values used in this documentation:

NSIP address=10.217.2.43

Entrust HSM IP address=10.217.2.112

RFS IP address=10.217.2.6

Add the NSIP address on the HSM

Typically you use the nShield Connect front panel to add clients to the HSM. For more information, see the nShield Connect Quick Start Guide.

Alternately, use the RFS to add the ADC as a client to the HSM. To add the ADC, you must add the NSIP address in the HSM configuration on the RFS, and then push the configuration to the HSM. Before you can push the configuration, you must know the electronic serial number (ESN) of the HSM.

To get the ESN of your HSM, run the following command on the RFS:

```
root@ns# /opt/nfast/bin/anonkneti <Entrust HSM IP address>
```

Example:

```
root@ns# /opt/nfast/bin/anonkneti 10.217.2.112
BD17-C807-58D9 5e30a698f7bab3b2068ca90a9488dc4e6c78d822
```

The ESN number is BD17-C807-58D9.

After you have the ESN number, use an editor, such as vi, to edit the HSM configuration file on the RFS.

```
vi /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

In the `hs_clients` section, add the following entries:

```
# Amount of data in bytes to encrypt with a session key before session
   key# renegotiation, or 0 for unlimitied. (default=1024*1024*8b=8Mb).
#  datalimit=INT
addr=10.217.2.43
clientperm=unpriv
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
keyhash=0000000000000000000000000000000000000000
esn=
timelimit=86400
datalimit=8388608
-----
```

Note: Include one or more hyphens as delimiters to add multiple entries in the same section.

To push the configuration to the HSM, run the following command on the RFS:

```
/opt/nfast/bin/cfg-pushnethsm --address=<Entrust HSM IP address> --
   force /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

Example:

```
/opt/nfast/bin/cfg-pushnethsm --address=10.217.2.112 --force
                /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

Configure access permission for the ADC on the RFS

To configure access permission for the ADC on the RFS, run the following command on the RFS:

```
/opt/nfast/bin/rfs-setup --force -g --write-noauth <NetScaler IP
   address>
```

Example:

```
[root@localhost bin]# /opt/nfast/bin/rfs-setup --force -g --write-
   noauth 10.217.2.43
Adding read-only remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local exists
Adding new writable remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local/sync-store exists
Saving the new config file and configuring the hardserver
Done
```

Verify that the ADC can reach both the RFS and Entrust HSM by using port 9004.

Configure automatic start of the `hardserver` at boot time

Create a file and then restart the appliance. Now, whenever you restart the appliance, and if this file is found, the `Hardserver` is automatically started.

At the shell prompt, type:

```
touch /var/opt/nfast/bin/thales_hsm_is_enrolled
```

At the command prompt, type:

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
reboot
```

Enroll the HSM on the ADC Change directory to /var/opt/nfast/bin.

To add HSM details into the ADC configuration, run the following command on the ADC:

```
nethsmenroll --force <Thales_nShield_Connect_ip_address> $(anonkneti <Thales_nShield_Connect_ip_address>)
```

Example:

```
root@ns# ./nethsmenroll --force 10.217.2.112 $(anonkneti 10.217.2.112)
OK configuring hardserver's nethsm imports
```

This step adds the following entries after the line # ntoken_esn=ESN in the `nethsm_imports` section of the /var/opt/nfast/kmdata/config/config file.

```
...
local_module=0
remote_ip=10.217.2.112
remote_port=9004
remote_esn=BD17-C807-58D9
keyhash=5e30a698f7bab3b2068ca90a9488dc4e6c78d822
timelimit=86400
datalimit=8388608
privileged=0
privileged_use_high_port=0
ntoken_esn=
```

Change the directory to /var/opt/nfast/bin and run the following command on the ADC:

```
touch "thales_hsm_is_enrolled"
```

Note: To remove an HSM that is enrolled on the ADC, type:

```
./nethsmenroll – -remove <NETHSM-IP>
```

Add RFS details on the ADC

To add RFS details, change the directory to /var/opt/nfast/bin/ and then run the following command:

```
./rfs-sync --no-authenticate --setup <rfs_ip_address>
```

Example:

```
./rfs-sync --no-authenticate --setup 10.217.2.6
No current RFS synchronization configuration.
```

© 1999–2025 Cloud Software Group, Inc. All rights reserved.

```
3 Configuration successfully written; new config details:
4 Using RFS at 10.217.2.6:9004: not authenticating.
```

This step adds the following entries after the # local_esn=ESN line in the `rfs_sync_client` section of the /var/opt/nfast/kmdata/config/config file.

```
1 ……
2 remote_ip=10.217.2.6
3 remote_port=9004
4 use_kneti=no
5 local_esn=
```

Note: To remove an RFS that is enrolled on the ADC, type:

```
1 ./rfs_sync – remove
```

Synchronize the ADC to the RFS

To synchronize all the files, change the directory to /var/opt/nfast/bin and then run the following command on the ADC:

```
1 ./rfs-sync – -update
```

This command fetches all the World files, module files, and key files from the /opt/nfast/kmdata/local directory on the RFS and puts them into the /var/opt/nfast/kmdata/local directory on the ADC. Citrix recommends that you manually copy the World files, the module_XXXX_XXXX_XXXX files, where XXXX_XXXX_XXXX is the ESN of the enrolled HSM, and only the required RSA key and certificate files.

Verify the Entrust HSM is successfully enrolled on the ADC

After you synchronize the ADC to the RFS, do the following:

- Verify that the local `Hardserver` is UP and running. (Entrust server running).
- Get the state of the configured HSMs, and verify that the values for the n_modules (number of modules) field and the km info fields are non-zero.
- Verify that the HSM is enrolled correctly and is usable (state 0x2 Usable) by the ADC.
- Load tests using `sigtest` run properly.
