About NetScaler CPX

October 17, 2023

NetScaler CPX is a container-based application delivery controller that can be provisioned on a Docker host. NetScaler CPX enables customers to leverage Docker engine capabilities and use NetScaler load balancing and traffic management features for container-based applications. You can deploy one or more NetScaler CPX instances as standalone instances on a Docker host.

A NetScaler CPX instance provides throughput of up to 1 Gbps.

As a containerized form factor of NetScaler, NetScaler CPX integrates well into the Kubernetes environment and forms an integral part of NetScaler cloud native solution. NetScaler cloud native solution helps you to create and deliver software applications with speed, agility, and efficiency in a Kubernetes environment. Using NetScaler cloud native solution, you can ensure enterprise grade reliability and security for your Kubernetes environment.

For more information, see [NetScaler cloud native solution](#).

This document assumes that you are familiar with Docker and how it works. For information about Docker, see the Docker documentation at <https://docs.docker.com>.

Supported Features

NetScaler CPX supports the following features:

- Application availability
 - L4 load balancing and L7 content switching
 - SSL offloading
 - IPv6 protocol translation
 - Microsoft SQL, MySQL load balancing
 - AppExpert rate controls
 - Subscriber-aware traffic steering
 - Surge protection and priority queuing
 - Dynamic routing protocols
- Application acceleration
 - Client and server TCP optimizations
 - Cache redirection
 - AppCompress
 - AppCache
- Application security

- L7 rewrite and responder
 - L4 DoS defenses
 - L7 DoS defenses
 - Web Application Firewall (WAF). NetScaler CPX supports all WAF features which are supported on other NetScaler form factors. For information about supported WAF features, see [NetScaler Web App Firewall](#).
 - Authentication, authorization, and auditing (AAA) for application traffic
- TCP protocol optimization
 - Multi-path TCP
 - Binary Increase Congestion Control (BIC) and cubic TCP
- Simple manageability
 - Web logging
 - AppFlow
 - NetScaler Application Delivery Management
 - Action analytics
- Application optimization
 - Integrated caching
- BGP Routing and Route Health Injection (RHI)
- High Availability (both Layer 2 and Layer 3)

Note:

Interface features such as Rx, Tx, GRO, GSO, and LRO are disabled for interfaces (Linux host) allocated to the NetScaler CPX appliance. These features remain in the disabled state even after the NetScaler CPX appliance is stopped. Also, the MTU is changed to 1500 bytes for such interfaces.

Supported Platforms

NetScaler CPX is supported on the following platforms:

- Kubernetes
- Red Hat OpenShift
- Public clouds
 - Amazon Elastic Kubernetes Service (EKS)
 - Azure Kubernetes Service (AKS)
 - Google Kubernetes Engine (GKE)
- Rancher

- Pivotal Container Service (PKS)
- Docker version 1.12 and above

Architecture and Traffic Flow

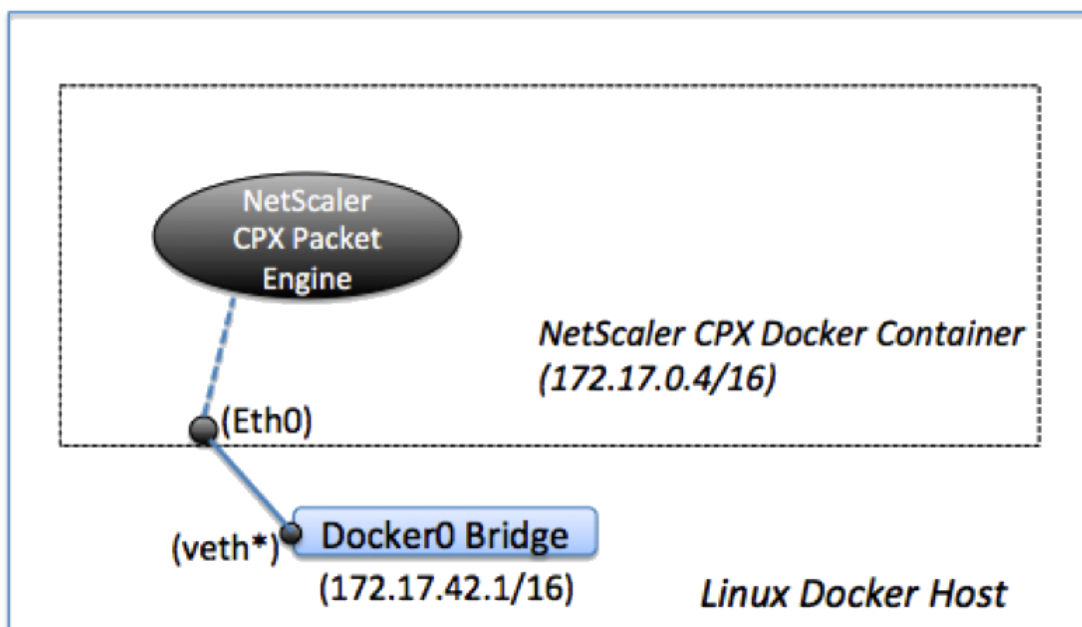

November 2, 2023

This section describes NetScaler CPX bridge mode architecture and traffic flow. NetScaler CPX can be deployed in host mode also.

When you provision a NetScaler CPX instance on a Docker host, the Docker engine creates a virtual interface, eth0, on the CPX instance. This eth0 interface is directly connected to a virtual interface (veth*) on the docker0 bridge. The Docker engine also assigns an IP address to the NetScaler CPX instance in the network 172.17.0.0/16.

The default gateway for the CPX instance is the IP address of the docker0 bridge, which means that any communication with the NetScaler CPX instance is done through the Docker network. All incoming traffic received from the docker0 bridge is received by the eth0 interface on the NetScaler CPX instance and processed by the NetScaler CPX packet engine.

The following figure illustrates the architecture of a NetScaler CPX instance on a Docker host.

How Single IP Address Works on NetScaler CPX

A regular NetScaler MPX or VPX appliance requires at least three IP addresses to function:

- Management IP address called the NetScaler IP (NSIP) address
- Subnet IP (SNIP) address for communicating with the server farm
- Virtual server IP (VIP) address(es) for accepting client requests

A NetScaler CPX instance operates with one single IP address that is used for management as well as for data traffic.

During provisioning, only one private IP address (single IP address) is assigned to a NetScaler CPX instance by the Docker engine. The three IP functions of a NetScaler instance are multiplexed onto one IP address. This single IP address uses different port numbers to function as the NSIP, SNIP, and VIP(s).

The following image illustrates how a single IP address is used to perform the functions of NSIP, SNIP, and VIP(s).

Traffic Flow for Requests Originating from the NetScaler CPX Instance

Docker implicitly configures IP tables and a NAT rule to direct traffic originating from the NetScaler CPX instance to the docker0 IP address.

The following figure illustrates how a ping request originating from a NetScaler CPX instance reaches the destination.

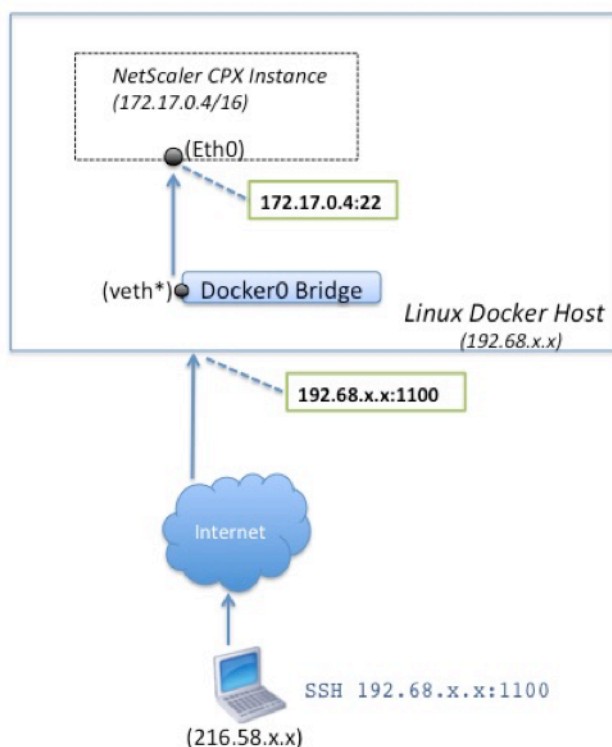

In this example, the ping request is sent by the packet engine on eth0 interface with source IP address as the NetScaler CPX IP address (172.17.0.4). The Docker host, then, performs network address translation (NAT) to add the host IP address (192.68.x.x) as the source IP address and sends the request to the destination (216.58.x.x). The response from the destination IP address follows the same path in reverse. The Docker host performs NAT on the response and forwards the response to the NetScaler CPX instance on the eth0 interface.

Traffic Flow for Requests Originating from the External Network

To enable external communication, while provisioning NetScaler CPX, you have to set parameters such that Docker exposes certain ports such as 80, 22, and any other port you want. If you have not set any port to be exposed during provisioning, then you have to configure NAT rules on the Docker host to make these ports available.

The client request that originates from the Internet is received by the Docker host, which then performs port address translation (PAT) to map the public IP address and port to the single IP address and port of the NetScaler CPX instance, and forwards the traffic to the instance.

The following figure shows how the Docker host performs port address translation to direct traffic to the NetScaler CPX single IP address and port.

In this example, the Docker host IP address is 192.68.x.x and the single IP address of the NetScaler CPX instance is 172.17.0.4. The SSH port 22 of NetScaler CPX instance is mapped to port 1100 on the Docker host. The SSH request from the client is received on IP address 192.68.x.x at port 1100. The Docker host performs port address translation to map this address and port to the single IP address 172.17.0.4 on port 22 and forwards the client request.

NetScaler CPX licensing

February 20, 2024

[NetScaler CPX](#) is a container-based application delivery controller that can be provisioned on a Docker host to load balance microservice based applications. You need licensed CPX for better performance

of application delivery. NetScaler CPX supports pool licensing. NetScaler ADM can act as your license server to license your NetScaler CPX instances.

NetScaler ADM is available both on-premises and a cloud service as well. You can use the NetScaler ADM to manage pooled capacity licenses for all NetScaler form factors.

For information about NetScaler ADM on-premises, see [NetScaler ADM on-premises](#). For information about NetScaler ADM service, see [NetScaler ADM service](#).

Types of NetScaler CPX licensing

NetScaler CPX supports bandwidth and virtual CPU (core) pool licensing for on-prem and cloud-based deployments.

Bandwidth pool: NetScaler CPX licenses can be allocated based on the bandwidth consumption by the instances. You can use pooled licensing to maximize the bandwidth utilization by ensuring the necessary bandwidth allocation to an instance and not more than its requirement. Currently, NetScaler CPX supports only premium bandwidth pool licensing.

vCPU pool: In the virtual CPU-usage-based licensing, the license specifies the number of CPUs that a particular NetScaler CPX instance is entitled to. So, the NetScaler CPX can check out licenses for only the number of virtual CPUs from the license server. NetScaler CPX checks out licenses depending on the number of CPUs running in the system. For more information about the vCPU pool, see [NetScaler virtual CPU licensing](#).

Supported pooled capacity for NetScaler CPX instances

Product	Maximum bandwidth	Minimum bandwidth	Minimum instances	Maximum instances	Minimum bandwidth unit
NetScaler CPX	40000 Note: It depends on CPU frequency, generation, and so on.	20 Mbps	1	16	10 Mbps

Note: Citrix is currently working on a NetScaler CPX consumption based or pay-as-you-grow based licensing model for public cloud-based offerings. Once ready, it will be available on the public cloud market place to consume.

How does NetScaler CPX licensing work?

NetScaler CPX pooled capacity: A common license pool from which your NetScaler CPX instance can check out one instance license and only as much bandwidth as it needs. When the instance no longer requires these resources, it checks them back in to the common pool, making the resources available to other instances which need these licenses.

NetScaler CPX check-in and check-out licensing: NetScaler ADM allocates licenses NetScaler CPX instances on demand. A NetScaler CPX instance can check out the license from the NetScaler ADM when a NetScaler CPX instance is provisioned and check back in its license to NetScaler ADM when an instance is destroyed.

NetScaler CPX behavior: A single NetScaler CPX instance checking-out up to 1 Gbps throughput, checks-out only from the instance pool and not from the bandwidth license pool. NetScaler CPX operates in this way up to the 1 Gbps of bandwidth utilization. For example, if a CPX instance consumes a 200 Mbps bandwidth, it uses the instance pool of license, instead of the bandwidth pool. However, if a NetScaler CPX instance consumes 1200 Mbps of throughput, the first 1000 Mbps is utilized from the instance pool and the remaining 200 Mbps is consumed from the bandwidth pool.

NetScaler CPX Express

NetScaler CPX Express is a software edition that is free-of-cost for on-premises and cloud deployments. When you download a NetScaler CPX instance from the [Quay](#) repository, the NetScaler CPX Express license is applied to the CPX instance by default. All the NetScaler CPX features are available with the NetScaler CPX Express license. For information about the supported features on CPX, see [About NetScaler CPX](#). The NetScaler community support is available with NetScaler CPX Express but not the enterprise support.

The NetScaler CPX Express license offers 100 Mbps bandwidth capacity. You must license your NetScaler CPX instance for higher capacity, production deployment, and to avail enterprise support.

Note:

Starting from NetScaler CPX version 14.1 build 14.1-17.38, the bandwidth of CPX Express license is increased from 20 Mbps to 100 Mbps. This increased bandwidth enables Kubernetes developers to try out NetScaler proxy.

NetScaler CPX licensing models

NetScaler offers a range of product licensing models for NetScaler CPX to meet your organization's requirements. You can select options such as vCPU or bandwidth and on-premises or cloud.

Based on your requirements, you can choose any of the following models:

- Bandwidth based licensing for NetScaler CPX from ADM service
- vCPU based licensing for NetScaler CPX from ADM service
- Bandwidth based licensing for NetScaler CPX from ADM on-premises
- vCPU based licensing for NetScaler CPX from ADM on-premises

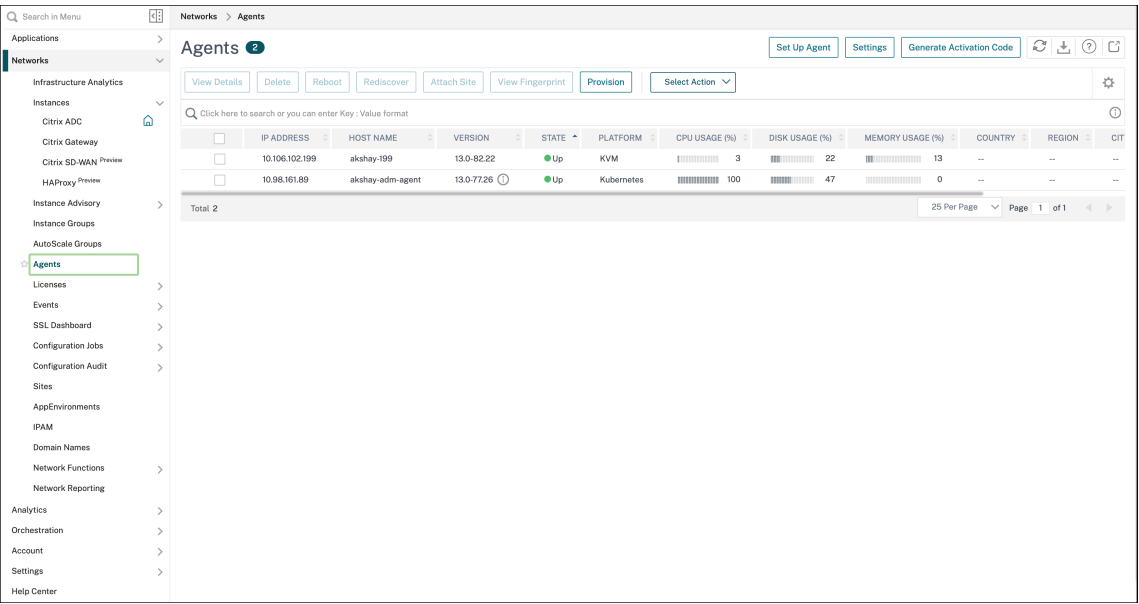

Provision bandwidth-based and vCPU-based licensing from NetScaler ADM service for NetScaler CPX

Perform the following steps to provision bandwidth-based license and vCPU-based license for NetScaler CPX from NetScaler ADM service.

1. Set up NetScaler ADM.

Ensure that the NetScaler ADM service setup is operational with the NetScaler ADM agent. You must have a NetScaler ADM service and NetScaler ADM agent account for NetScaler CPX licensing to be functional. For information about setting up NetScaler ADM service and NetScaler ADM agent, see [NetScaler ADM service](#).

Note: In this procedure, a hypervisor (on-premises) NetScaler ADM agent setup is used. In the following image, 10 . 106 . 102 . 199 is the on-premises agent used for licensing NetScaler CPX.

2. Add NetScaler instance license pool to NetScaler ADM service.

It is assumed that you have a pool of bandwidth licenses available for ADM service. For information about uploading a license file to NetScaler ADM, see [Configure pooled capacity](#). In the following image, `CNS_INST_200CC_Retail.lic` is used as the bandwidth and instance license pool.

3. Deploy NetScaler CPX instance in Kubernetes cluster. Ensure that the following environment variables are added to the NetScaler CPX YAML file to license the NetScaler CPX instance.

For the bandwidth-based licensing from the NetScaler ADM service, specify the following environment variables in the YAML file:

- name: "LS_IP"
value: "10.105.158.166"//ADM agent IP as mentioned in step 1
- name: "LS_PORT"
value: "27000"// port on which ADM license server listens
- name: "BANDWIDTH"
value: "3000"//capacity in Mbps wants to allocate to CPX
- name: "EDITION"
value: "Standard"or "Enterprise"//to choose a particular license edition that includes Standard, Platinum, and Enterprise. By default, Platinum is selected.

For the vCPU-based licensing from the NetScaler ADM service, specify the following environment variables in the YAML file:

- name: "LS_IP"
value: "10.102.216.173"//ADM agent IP as mentioned in step 1
- name: "LS_PORT"
value: "27000"// port on which ADM license server listens to
- name: "CPX_CORES"
value: "4"// number of core you want to allocate
- name: "PLATFORM"
value: "CP1000"// number of cores. Check-out count is equal to the number of cores.

4. Download the `cpx-bandwidth-license-adm-service.yaml` file using the following

command:

```
1 kubectl create namespace bandwidth
2 wget https://raw.githubusercontent.com/citrix/cloud-native-
  getting-started/master/cpx-licensing/manifest/cpx-bandwidth-
  license-adm-service.yaml
```

5. Deploy the edited YAML in the Kubernetes cluster using the following command:

```
1 kubectl create -f cpx-bandwidth-license-adm-service.yaml -n
  bandwidth
```

6. Log in to NetScaler CPX for verifying instancing information by using the following command:

```
1 kubectl exec -it 'cpx-pod-ip-name' bash -n bandwidth
```

7. To view the licensing information for the given NetScaler CPX instance, run the following commands:

```
1 cli_script.sh "show licenseserver"
2 cli_script.sh "show capacity"
```

You can track the allocated bandwidth and vCPU capacity in the ADM service portal.

Provision Bandwidth based licensing and vCPU based licensing for NetScaler CPX from NetScaler ADM on-premises

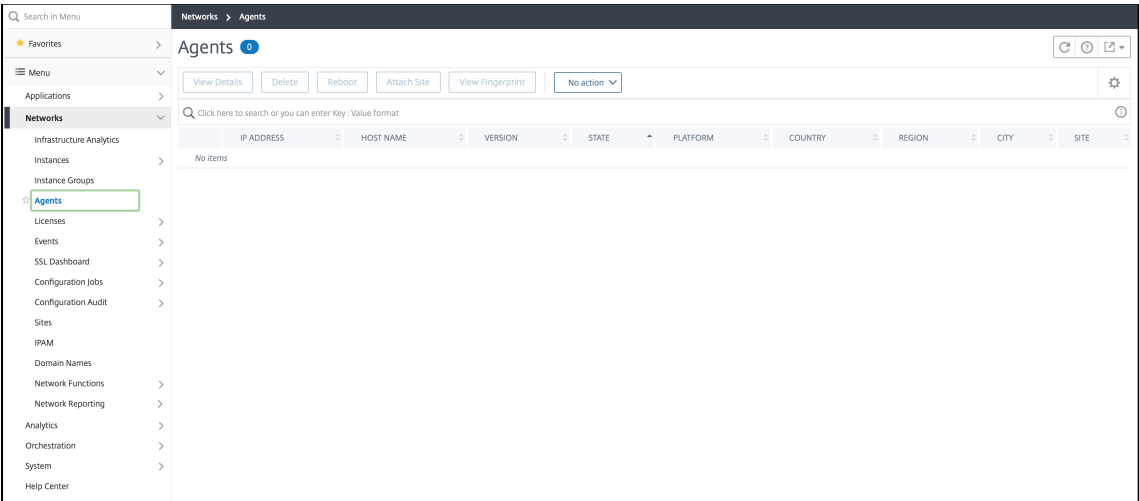

Perform the following steps to provision bandwidth-based and vCPU-based to NetScaler CPX from NetScaler ADM on-premises.

1. Set up NetScaler ADM.

Ensure that the ADM on-premises setup is ready. Make sure that NetScaler ADM on-premises with or without ADM agent deployment for NetScaler CPX licensing is functioning.

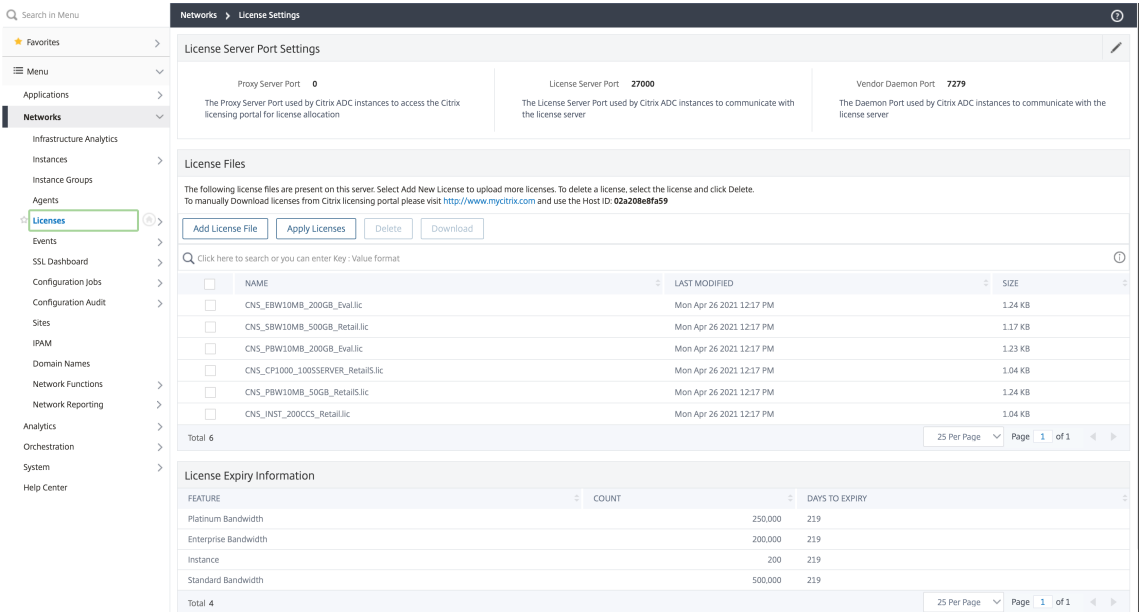

For information about setting up NetScaler ADM on-premises and NetScaler ADM agent, see [NetScaler ADM service](#).

Note: In this example, an in-built ADM agent with ADM on-premises is used. In the following image, you can see that there is no agent deployed.

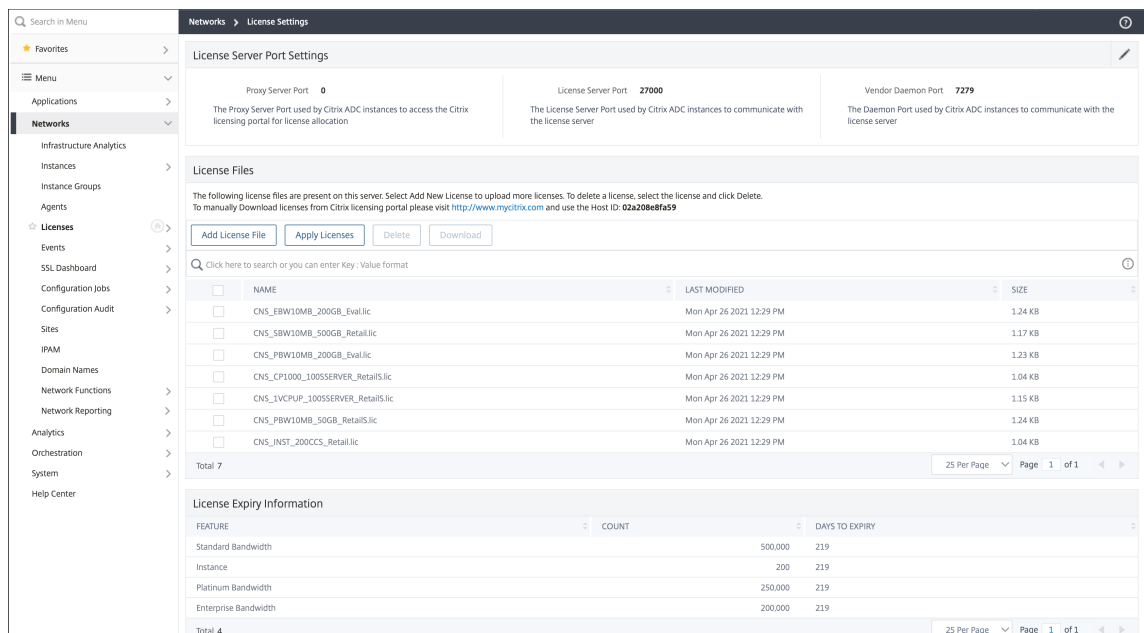

2. Add NetScaler instance license pool to ADM on-premises.

It is assumed that you have a pool of bandwidth license available for ADM on-premises. To know about uploading a license file to NetScaler ADM, see [Licensing](#). In the following image, `CNS_INST_200CC_Retail.lic` is used as the bandwidth and instance license pool.

In the following image, CP1000 is used as the vCPU license pool.

3. Deploy NetScaler CPX instance in Kubernetes cluster. Ensure that the following environment variables are added to the NetScaler CPX YAML file to license the NetScaler CPX instance.

For the bandwidth-based licensing from NetScaler ADM on-premises, specify the following environment variables in the YAML file:

- name: "LS_IP"
value: "10.105.158.144"// ADM on-prem instance IP, If you have deployed ADM agent, then this is your agent IP address as described in the step 1
- name: "LS_PORT"
value: "27000"// port on which ADM license server listens
- name: "BANDWIDTH"
value: "3000"//capacity in Mbps wants to allocate to CPX

For the vCPU-based licensing from NetScaler ADM on-premises, specify the following environment variables in the YAML file:

- name: "LS_IP"
value: "10.105.158.144"// ADM on-prem instance IP, If you have ADM agent deployment then this will be your agent IP as described in step 1
- name: "LS_PORT"
value: "27000"// port on which ADM license server listens to
- name: "CPX_CORES"
value: "4"// the number of cores that you want to allocate
- name: "PLATFORM"
value: "CP1000"// number of cores. Check-out count is equal to the number of cores.

4. Download the `cpx-bandwidth-license-adm-onprem.yaml` file using the following command:

```
1 kubectl create namespace bandwidth
2 wget https://raw.githubusercontent.com/citrix/cloud-native-getting-started/master/cpx-licensing/manifest/cpx-bandwidth-license-adm-onprem.yaml
```

5. Deploy the edited YAML in the Kubernetes cluster using the following command:

```
1 kubectl create -f cpx-bandwidth-license-adm-onprem.yaml -n bandwidth
```

6. Log in to NetScaler CPX for verifying instancing information by using the following command:

```
1 kubectl exec -it <cpx-pod-ip-name> bash -n bandwidth
```

7. To view the licensing information for the NetScaler CPX instance, run the following commands:

```
1 cli_script.sh "show licenseserver"
2 cli_script.sh "show capacity"
```

You can track the allocated bandwidth and vCPU capacity in the ADM on-premises portal.

Commands for cleaning the deployments

You can use the following commands to clean the various YAML deployments:

```
1 kubectl delete -f cpx-bandwidth-license-adm-service.yaml -n bandwidth
2 kubectl delete -f cpx-core-license-adm-service.yaml -n core
3 kubectl delete -f cpx-bandwidth-license-adm-onprem.yaml -n bandwidth
4 kubectl delete -f cpx-core-license-adm-onprem.yaml -n core
5 kubectl delete namespace bandwidth
6 kubectl delete namespace core
```

Deploying a NetScaler CPX Instance in Docker

December 26, 2023

NetScaler CPX instances are available as a Docker image file in the Quay container registry. To deploy an instance, download the NetScaler CPX image from the Quay container registry and then deploy the instance by using the `docker run` command or the Docker compose tool.

Prerequisites

Make sure that:

- Docker host system has at least:
 - 1 CPU
 - 2 GB RAM

Note: For better NetScaler CPX performance, you can define the number of processing engines that you want the NetScaler CPX instance to start. For every additional processing engine, you add, make sure that the Docker host contains the equivalent number of vCPUs and amount of memory in GB. For example, if you want to add 4 processing engines, the Docker host must contain 4 vCPUs and 4 GB of memory.

- Docker host system is running Linux Ubuntu version 14.04 or later.
- Docker version 1.12 is installed on the host system. For information about Docker installation on Linux, see the [Docker Documentation](#).
- Docker host has Internet connectivity.

Note: NetScaler CPX has issues while running on ubuntu version 16.04.5, kernel version 4.4.0-131-generic. So, it is not recommended to run NetScaler CPX on ubuntu version 16.04.5 kernel version 4.4.0-131-generic.

Note: The following kubelet and kube-proxy versions have some security vulnerabilities and it is not recommended to use Citrix NetScaler CPX with these versions:

- kubelet/kube-proxy v1.18.0-1.18.3
- kubelet/kube-proxy v1.17.0-1.17.6
- kubelet/kube-proxy <=1.16.10

For information on how to mitigate this vulnerability, see [Mitigate this vulnerability](#).

Downloading NetScaler CPX Image from Quay

You can download the NetScaler CPX image from the Quay container registry using the `docker pull` command and deploy it on your environment. Use the following command to download the NetScaler CPX image from the Quay container registry:

```
1 docker pull quay.io/citrix/citrix-k8s-cpx-ingress:13.0-xx.xx
```

For example, if you want to download the version 13.0-64.35, then use the following command:

```
1 docker pull quay.io/citrix/citrix-k8s-cpx-ingress:13.0-64.35
```

Use the following command to verify if the NetScaler CPX image is installed in docker images:

```
1 root@ubuntu:~# docker images | grep 'citrix-k8s-cpx-ingress'
2 quay.io/citrix/citrix-k8s-cpx-ingress 13.0-64.35
952a04e73101 2 months ago 469 MB
```

You can deploy the latest NetScaler CPX image from the [Quay container registry](#).

Deploying the NetScaler CPX Instance Using the docker run Command

On the host, you can install a NetScaler CPX instance in the Docker container by using the NetScaler CPX Docker image that you loaded onto the host. Using the `docker run` command, install the NetScaler CPX instance with the default NetScaler CPX configuration.

Important:

If you have downloaded NetScaler CPX Express from [CPX Express](#), make sure that you read and understand the End User License Agreement (EULA) available at: [CPX Express](#) and accept the EULA while deploying the NetScaler CPX instance.

Install the NetScaler CPX instance on the Docker container by using the following **`docker run`** command:

```
1 docker run -dt -P --privileged=true --net=host -e NS_NETMODE="HOST"
   -e CPX_CORES=<number of cores> --name <container_name> --ulimit core
   =-1 -e CPX_NW_DEV='<INTERFACES>' -e CPX_CONFIG=' {
2   "YIELD" : "NO" }
3   ' -e LS_IP=<LS_IP_ADDRESS> -e LS_PORT=<LS_PORT> -e PLATFORM=CP1000 -v
   <host_dir>:/cpx <REPOSITORY>:<TAG>
4 <!--NeedCopy-->
```

```
1 docker run -dt --privileged=true --net=host -e NS_NETMODE="HOST" -e
   CPX_NW_DEV='eth1 eth2' -e CPX_CORES=5 -e CPX_CONFIG='{
2   "YIELD":"No" }
3   ' -e LS_IP=10.102.38.134 -e PLATFORM=CP1000 -v /var/cpx:/cpx --name
   cpx_host cpx:13.0-x.x
4 <!--NeedCopy-->
```

This example creates a container named `mycpx` based on the NetScaler CPX Docker image.

The `-P` parameter is mandatory. It tells Docker to map the ports exposed in the container by the NetScaler CPX Docker image. That means mapping ports 9080, 22, 9443, and 161/UDP, to the ports on the Docker host that are randomly selected from the user-defined range. This mapping is done to avoid conflicts. If you later create multiple NetScaler CPX containers on the same Docker host. The port mappings are dynamic and are set each time the container is started or restarted. The ports are used as follows:

- 9080 is used for HTTP

- 9443 is used for HTTPs
- 22 used for SSH
- 161/UDP is used for SNMP.

If you want static port mappings, use the `-p` parameter to set them manually.

The `--privileged=true` option is used to run the container in privileged mode. If you are running the NetScaler CPX in Host mode of deployment then you need to provide all the system privileges to the NetScaler CPX.

To run the NetScaler CPX in bridge mode with a single or multiple cores, you can use the `--cap-add=NET_ADMIN` option instead of the privileged mode. The `--cap-add=NET_ADMIN` option enables you to run the NetScaler CPX container with full network privileges. With the `--cap-add=NET_ADMIN` option, use the `--sysctl kernel.shmmax=1073741824 --sysctl net.ipv6.conf.default.accept_dad=0 --sysctl kernel.core_pattern=/var/crash/core.%e.%p.%s` option in the docker run command to do the additional system control settings manually. These additional system control settings aren't done automatically under any non-privileged modes.

The `*--net=host` is a standard docker run command option that specifies that the container is running in the host network stack and has access to all the network devices.

Note

Ignore this option, if you are running NetScaler CPX in bridge or none network.

The `-e NS_NETMODE="HOST"` is a NetScaler CPX specific environment variable that allows you to specify that the NetScaler CPX is started in host mode. Once NetScaler CPX starts in host mode it configures 4 default iptables rules on a host machine for management access to the NetScaler CPX. It uses the following ports:

- 9995 for HTTP
- 9996 for HTTPS
- 9997 for SSH
- 9998 for SNMP

If you want to specify different ports, you can use the following environment variables:

- `-e NS_HTTP_PORT=`
- `-e NS_HTTPS_PORT=`
- `-e NS_SSH_PORT=`
- `-e NS_SNMP_PORT=`

Note

Ignore this environment variable, if you are running NetScaler CPX in bridge or none network.

The `-e CPX_CORES` is an optional NetScaler CPX specific environment variable. You can use it to improve the performance of the NetScaler CPX instance by defining the number of processing engines that you want the NetScaler CPX container to start.

Note: NetScaler CPX can support from 1 to 16 cores.

Note

For every additional processing engine you add, make sure that the Docker host contains the equivalent number of vCPUs and amount of memory in GB. For example, if you want to add 4 processing engines, then the Docker host must contain 4 vCPUs and 4 GB of memory.

The `-e EULA = yes` is a mandatory NetScaler CPX specific environment variable, which is required to verify that you have read and understand the End User License Agreement (EULA) available at: [CPX Express](#).

The `-e PLATFORM=CP1000` parameter specifies the NetScaler CPX license type.

If you are running Docker in a host network, you can assign dedicated network interfaces to the NetScaler CPX container using the `-e CPX_NW_DEV` environment variable. You need to define the network interfaces separated by a whitespace. The network interfaces that you define are held by the NetScaler CPX container until you uninstall the NetScaler CPX container. When the NetScaler CPX container is provisioned all the assigned network interfaces are added to the NetScaler networking namespace.

Note

If you are running NetScaler CPX in bridge network you may change the container network, such as, configure another network connection to the container or remove an existing network. Then make sure that you restart the NetScaler CPX container to use the updated network.

```
1 docker run -dt --privileged=true --net=host -e NS_NETMODE="HOST" -e  
    EULA=yes -e CPX_NW_DEV='eth1 eth2' -e CPX_CORES=5 -e PLATFORM=CP1000  
    --name cpx_host cpx:13.0-x.x  
2 <!--NeedCopy-->
```

The `-e CPX_CONFIG` is a NetScaler CPX specific environment variable that enables you to control the throughput performance of the NetScaler CPX container. When the NetScaler CPX does not receive any incoming traffic to process, it yields the CPU during this idle time, hence resulting in low throughput performance. You can use the `CPX_CONFIG` environment variable to control the throughput performance of the NetScaler CPX container in such scenarios. You need to provide following values to the `CPX_CONFIG` environment variable in JSON format:

- If you want the NetScaler CPX container to yield CPU in idle scenarios, define { "YIELD" : "Yes" }
- If you want the NetScaler CPX container to avoid yielding the CPU in idle scenarios so that you can get high throughput performance, define { "YIELD" : "No" }

```
1 docker run -dt --privileged=true --net=host -e NS_NETMODE="HOST" -e  
    EULA=yes -e CPX_CORES=5 -e CPX_CONFIG='{  
2   "YIELD":"No" }  
3   ' -e PLATFORM=CP1000 --name cpx_host cpx:13.0-x.x  
4 <!--NeedCopy-->
```

```
1 docker run -dt --privileged=true --net=host -e NS_NETMODE="HOST" -e  
    EULA=yes -e CPX_CORES=5 -e CPX_CONFIG='{  
2   "YIELD":"Yes" }  
3   ' -e PLATFORM=CP1000 --name cpx_host cpx:13.0-x.x  
4 <!--NeedCopy-->
```

The `-v` parameter is an optional parameter that specifies the mount point of the NetScaler CPX mount directory, `/cpx`. A mount point is a directory on the host, in which you mount the `/cpx` directory. The `/cpx` directory stores the logs, configuration files, SSL certificates, and core dump files. In the example, the mount point is `/var/cpx` and the NetScaler CPX mount directory is `/cpx`.

If you purchased a license or have an evaluation license, you can upload the license to a license server and specify the license server location with the docker run command, by using the `-e LS_IP=<LS_IP_ADDRESS> -e LS_PORT=<LS_PORT>` parameter. In this case, you do not need to accept the EULA.

```
1 docker run -dt --privileged=true --net=host -e NS_NETMODE="HOST" -e  
    CPX_CORES=5 -e CPX_CONFIG='{  
2   "YIELD":"No" }  
3   ' -e LS_IP=10.102.38.134 -e PLATFORM=CP1000 --name cpx_host cpx:13.0-x  
    .x  
4 <!--NeedCopy-->
```

Where:

- `LS_IP_ADDRESS` is the IP address of the license server.
- `LS_PORT` is the port of the license server.

You can view the images running on your system and the ports mapped to the standard ports by using the command: `docker ps`

Deploying a Lighter Version of NetScaler CPX Using the docker run Command

NetScaler provides a lighter version of NetScaler CPX which consumes lesser runtime memory. The lighter version of NetScaler CPX can be deployed as a sidecar in service-mesh deployments.

The lighter version of NetScaler CPX supports the following features:

- Application availability
 - L4 load balancing and L7 content switching
 - SSL Offloading
 - IPv6 protocol translation
- Application security
 - L7 rewrite and responder
- Simple manageability
 - Web logging
 - AppFlow

To instantiate the lighter version of NetScaler CPX, set the `NS_CPX_LITE` environment variable while executing the `Docker run` command.

```
1 docker run -dt -P --privileged=true -e NS_CPX_LITE=1 -e EULA=yes --name  
   <container_name> --ulimit core=-1 <REPOSITORY>:<TAG>  
2 <!--NeedCopy-->
```

The following example creates a lightweight container based on the NetScaler CPX image.

```
1 docker run -dt -P --privileged=true -e NS_CPX_LITE=1 -e EULA=yes --  
   name lightweight --ulimit core=-1 cpx:latest  
2 <!--NeedCopy-->
```

By default, logging using `newnslog` is disabled on the lighter version of NetScaler CPX. To enable it, you must set the `NS_ENABLE_NEWNSLOG` environment variable to 1 while bringing up the lighter version of NetScaler CPX.

The following example shows how to enable logging using `newnslog` while deploying the lighter version of NetScaler CPX.

```
1 docker run -dt --privileged=true --ulimit core=-1 -e EULA=yes -e  
   NS_CPX_LITE=1 -e NS_ENABLE_NEWNSLOG=1 cpx:<tag>  
2 <!--NeedCopy-->
```

Note: The lighter version of CPX supports only single core (CPX_CORES=1).

Deploying NetScaler CPX Instances by Using Docker Compose

You can use the Compose tool of Docker to provision a single NetScaler CPX instance or multiple NetScaler CPX instances. To provision NetScaler CPX instances by using Docker Compose, you must first write a compose file. This file specifies the NetScaler CPX image, the ports that you want to open for the NetScaler CPX instance, and the privileges for your NetScaler CPX instance.

Important

Make sure that you have installed Docker Compose tool on the host.

To provision multiple NetScaler CPX instances:

1. Write a compose file, where:

- **<service-name>** is the name of the service you want to provision.
- **image:<repository>:<tag>** denotes the repository and the versions of the NetScaler CPX image.
- **privileged: true** provides all root privileges to the NetScaler CPX instance.
- **cap_add** provides network privileges to the NetScaler CPX instance.
- **<host_directory_path>** denotes the directory on the docker host that you want to mount for the NetScaler CPX instance.
- **<number_processing_engine>** is the number of processing engines that you want the NetScaler CPX instance to start. For every additional processing engine, make sure that the Docker host contains the equivalent number of vCPUs and amount of memory in GB. For example, if you want to add 4 processing engines, then the Docker host must contain 4 vCPUs and 4 GB of memory.

The compose file generally follows a format similar to:

```

1     <service-name>:
2     container_name:
3     image: <repository>:<tag>
4     ports:
5         - 22
6         - 9080
7         - 9443
8         - 161/udp
9         - 35021-35030
10    tty: true
11    cap_add:
12        - NET_ADMIN
13    ulimits:
14        core: -1
15    volumes:
16        - <host_directory_path>:/cpx
17    environment:
18        - EULA=yes
19        - CPX_CORES=<number_processing_engine>
20        - CPX_CONFIG='{
21    "YIELD":"Yes" }
22    '
23    <!--NeedCopy-->

```

```

1     CPX_0:
2     image: quay.io/citrix/citrix-k8s-cpx-ingress:13.1-37.38

```

```
3     ports:
4         - 9443
5         - 22
6         - 9080
7         - 161/udp
8     tty: true
9     cap_add:
10        - NET_ADMIN
11    ulimits:
12        core: -1
13    volumes:
14        - /root/test:/cpx
15    environment:
16        - CPX_CORES=2
17        - EULA=yes
18    <!--NeedCopy-->
```

Adding NetScaler CPX Instances to NetScaler ADM

November 2, 2023

You must add the NetScaler CPX instances installed on a Docker host to NetScaler Application Delivery Management (ADM) software if you want to manage and monitor these instances.

You can add instances either while setting up ADM for the first time or later.

To add instances, you must create an instance profile and specify either the host name or IP address of each instance, or a range of IP addresses. This instance profile contains the user name and password of the instances that you want to add to NetScaler ADM. For each instance type, a default profile is available. For example, the `ns-root-profile` is the default profile for NetScaler instances. This profile is defined by the default ADC administrator credentials. If you have changed the default admin credentials of your instances, you can define custom instance profiles for those instances. If you change the credentials of an instance after the instance is discovered, you must edit the instance profile or create a profile, and then rediscover the instance.

Prerequisites

Make sure that you have:

- Installed the NetScaler ADM software on Citrix XenServer. For more information, see [NetScaler ADM Documentation](#).
- Installed the NetScaler CPX instances on a Docker host.

To add NetScaler CPX instances to ADM:

1. In a web browser, type the IP address of the **NetScaler Application Delivery Management** (for example, <http://192.168.100.1>).
2. In the **User Name** and **Password** fields, enter the administrator credentials. The default administrator credentials are **nsroot** and **nsroot**.
3. Navigate to **Networks > Instances > NetScaler** and click **CPX** tab.
4. Click **Add** to add new CPX instances in NetScaler ADM.
5. The **Add NetScaler CPX** page opens. Enter the values for the following parameters:
 - a) You can add CPX instances by providing either the reachable IP address of the CPX instance or the IP address of the Docker container where the CPX instance is hosted.
 - b) Select the profile of the CPX instance.
 - c) Select the site where the instances are to be deployed.
 - d) Select the agent.
 - e) As an option, you can enter the key-value pair to the instance. Adding a key-value pair makes it easy for you to search for the instance later.

← Add NetScaler CPX

☒ Enter Device IP Address ☐ Import from file

Enter one or more hostnames, IP addresses, and/or a range of IP addresses (for example, 10.102.40.30-10.102.40.45) using a comma separator.

☒ Enable Device addition on first time login failure

Routable IP/ Docker IP*

172.31.32.161

Tags

Key Value +

OK Close

6. Click **OK**.

Note

If you want to rediscover an instance, choose **Networks > Instances > NetScaler > CPX**, select the instance you want to rediscover, and then from the **Select Action** drop-down list, click **Re-**

discover.**Adding NetScaler CPX instances to NetScaler ADM using environment variables**

You can also add the NetScaler CPX instances to NetScaler ADM using environment variables. To add instances, you must configure the following environment variables for the NetScaler CPX instance.

- **NS_MGMT_SERVER** - ADM IP address/FQDN
- **HOST** - Node IP address
- **NS_HTTP_PORT** - Mapped HTTP port on node
- **NS_HTTPS_PORT** - Mapped HTTPS port on node
- **NS_SSH_PORT** - Mapped SSH port on node
- **NS_SNMP_PORT** - Mapped SNMP port on node
- **NS_ROUTABLE** - (NetScaler CPX pod IP address is not routable from outside.)
- **NS_MGMT_USER** -ADM username
- **NS_MGMT_PASS** -ADM password

The following is an example **docker run** command for adding a NetScaler CPX instance to NetScaler ADM.

```
1  docker run -dt --privileged=true -p 9080:9080 -p 9443:9443 -p 9022:22
    -p 9161:161 -e EULA=yes -e NS_MGMT_SERVER=abc-mgmt-server.com -e
    HOST=10.1.1.1 -e NS_HTTP_PORT=9080 -e NS_HTTPS_PORT=9443 -e
    NS_SSH_PORT=9022 -e NS_SNMP_PORT=9161 -e NS_ROUTABLE=0 --ulimit
    core=-1 -name test cpx:latest
2
3  <!--NeedCopy-->
```

Adding NetScaler CPX instances to NetScaler ADM using Kubernetes ConfigMaps

NetScaler CPX supports registration with NetScaler ADM by using volume mounted files through Kubernetes ConfigMaps. To enable this way of registration, NetScaler CPX requires some environment variables which are to be specified along with some volume mounted files through ConfigMaps and Secrets.

The following are the required environment variables and their description:

- **NS_HTTP_PORT** - Specifies mapped HTTP port on node.
- **NS_HTTPS_PORT** - Specifies mapped HTTPS port on node.
- **NS_SSH_PORT** - Specifies mapped SSH port on node.
- **NS_SNMP_PORT** - Specifies mapped SNMP port on node.

Apart from the listed environment variables, NetScaler CPX requires information about the ADM agent with which it has to register. This information contains ADM agent's IP address or FQDN details and

credentials. NetScaler CPX acquires this information from the volume mounted files. A ConfigMap containing the IP address or FQDN is mounted as a file in the file-system of the NetScaler CPX instance. A Kubernetes secret containing credentials for the ADM agent is also mounted as a file in the NetScaler CPX instance's file-system. With all the information required for registration, NetScaler CPX attempts to register with the ADM agent.

The following is an example of a NetScaler CPX YAML file snippet with the ConfigMap and Secret mounted as files:

```
1      ...
2      env:
3        - name: "EULA"
4          value: "yes"
5        - name: "NS_HTTP_PORT"
6          value: "9080"
7        - name: "NS_HTTPS_PORT"
8          value: "9443"
9        - name: "NS_SSH_PORT"
10         value: "22"
11        - name: "NS_SNMP_PORT"
12         value: "161"
13        - name: "KUBERNETES_TASK_ID"
14         value: ""
15      ...
16      volumeMounts:
17        ...
18        - mountPath: /var/admininfo/server/
19          name: adm-agent-config
20        - mountPath: /var/admininfo/credentials/
21          name: adm-agent-user
22      ...
23      volumes:
24      ...
25      - name: adm-agent-config
26        configMap:
27          name: adm-agent-config
28      - name: adm-agent-user
29        secret:
30          secretName: adm-secret
```

In the preceding example, a ConfigMap named `adm-agent-config` and a secret `adm-agent-user` are consumed. The following is an example for creating the required ConfigMap and Secret.

ConfigMap: The ConfigMap is created from a file named `adm_reg_envs`. The file requires the IP address or FQDN of the ADM agent in the following format:

```
1  NS_MGMT_SERVER=adm-agent
```

In the preceding format, the `adm-agent` is the FQDN of the ADM agent to which the NetScaler CPX instance needs to be registered.

Use the following command to create a ConfigMap:

```
1 kubectl create configmap adm-agent-config --from-file=adm_reg_envs
```

Note: The file name must have the `adm_reg_envs` variable and it must be mounted to the path: `/var/adminfo/server/`.

Secret: Use the following command to create a Kubernetes secret. In the following command, `user123` is the user name of the ADM agent and `pass123` is the password.

```
1 kubectl create secret generic adm-secret --from-literal=NS_MGMT_USER=
  user123 --from-literal=NS_MGMT_PASS=pass123
```

A NetScaler CPX instance can be deployed in a Kubernetes cluster with the required environment variables and volume mounted files even before deploying the ADM agent in the cluster. If you deploy a NetScaler CPX instance before deploying the ADM agent, NetScaler CPX keeps on trying to get registered until the ADM agent is deployed. Once the ADM agent is deployed, the NetScaler CPX instance uses the configuration data provided through the environment variables and volume mounted files to register with the ADM agent. It helps you to avoid the redeployment of NetScaler CPX with the configuration information.

A NetScaler CPX instance, that is already registered with an ADM agent, can dynamically change the registration to another ADM agent after a change in the configuration. For this, you can update configuration information in the ConfigMap and the Secret for the already deployed NetScaler CPX. You must update the file from which the ConfigMap is created with the IP address or FQDN of the new ADM agent and delete the old ConfigMap and, then create a new ConfigMap. Similarly, the existing secret must be deleted and a new secret must be created with the credentials for the new ADM agent.

NetScaler CPX License Aggregator

November 2, 2023

Currently, NetScaler CPXs obtain licenses from the NetScaler ADM server. In a Kubernetes environment, NetScaler CPXs can dynamically come up or go down. If a NetScaler CPX unexpectedly goes down, it takes few minutes for the NetScaler ADM server to reclaim the license. The NetScaler ADM server must be able to reclaim such licenses immediately as and when NetScaler CPXs go down so that the same license can be allocated to another upcoming NetScaler CPX. Also, if the NetScaler ADM server is not reachable for any reason, you cannot license new NetScaler CPXs in the cluster.

NetScaler CPX License Aggregator is a Kubernetes service provided by NetScaler. This service acts as a local provider for NetScaler CPX licensing within a Kubernetes cluster. The NetScaler CPX License Aggregator service deployed in a Kubernetes cluster can act as an intermediary between NetScaler

CPXs and the ADM licensing server and keep track of NetScaler CPXs and the allotted licenses. With the NetScaler CPX License Aggregator service, the NetScaler ADM server can reclaim licenses immediately as and when NetScaler CPXs goes down.

In a Kubernetes cluster, the NetScaler CPX License Aggregator service supports both NetScaler CPX as sidecar and standalone deployments.

Note:

Licensing using NetScaler CPX License Aggregator requires NetScaler CPX 13.1-30.x or later. NetScaler CPX License Aggregator does not support licensing the older versions of NetScaler CPX.

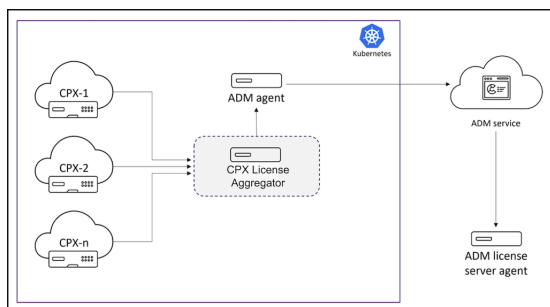

Key benefits of NetScaler CPX License Aggregator

The following are the key benefits of using NetScaler CPX License Aggregator:

- **Scalability:**
A NetScaler ADM licensing server can support only up to 10000 NetScaler CPX deployments. With the introduction of NetScaler CPX License Aggregator service, each Kubernetes cluster can act as a single client to the NetScaler ADM licensing server. Hence, you can scale many NetScaler CPXs with a single NetScaler ADM licensing server.
- **Resource optimization:**
The NetScaler CPX License Aggregator service also supports cluster-wide licensing capability and it can also check out licenses from the NetScaler ADM server on a need basis. NetScaler CPX License Aggregator can return licenses back to the NetScaler ADM server.
NetScaler CPX License Aggregator can handle ungraceful termination of NetScaler CPXs and reclaim licenses from such NetScaler CPXs after the configured waiting period.

Deployment topology

The following diagram shows a NetScaler CPX License Aggregator deployment within a Kubernetes cluster.

In this diagram:

- **CPX** means NetScaler CPX
- **CPX License Aggregator** means NetScaler CPX License Aggregator

In this sample deployment, a NetScaler CPX License Aggregator service is deployed within the Kubernetes cluster along with NetScaler CPXs and NetScaler ADM agent. The NetScaler CPX License Aggregator service acts as an intermediary between NetScaler CPXs and NetScaler ADM agent and monitors all NetScaler CPXs within the cluster and manages licenses to them.

Deploy NetScaler CPX License Aggregator using Helm charts

Prerequisites

The following prerequisites apply:

- You need Kubernetes version 1.16 and later.
- You need the Helm version 3.x or later.
- You must get the IP address of the license server that has the license for NetScaler CPX.
- You must provide a password for the Redis database in NetScaler CPX License Aggregator. You can provide the database password using the Kubernetes secret and the following command can be used to create the secret:

```
1 kubectl create secret generic dbsecret --from-literal=password=<
  custom-password>
```

Deployment using Helm charts

Do the following steps to deploy NetScaler CPX License Aggregator using Helm charts depending on the type of NetScaler CPX license. For more information about the different type of NetScaler CPX licenses, see [NetScaler CPX licensing](#).

Installing the Helm chart Add the NetScaler CPX License Aggregator Helm chart repository using the following command:

```
1 helm repo add Citrix https://citrix.github.io/citrix-helm-charts/
```

Installing NetScaler CPX License Aggregator to manage bandwidth pooled licenses Use one of the following commands depending on the type of NetScaler CPX pooled license that you have. In these commands, `my-release` is used as the release name.

Note:

By default, the Helm chart installs the recommended RBAC roles and role bindings.

For platinum bandwidth license:

```
1 helm install my-release citrix/cpx-license-aggregator --set
  licenseServer.address=<License-Server-IP-or-FQDN>,redis.
  secretName=<Kubernetes-Secret-for-DB-password>,licenseAggregator
  .username=<unique-ID-for-CLA>,licenseInfo.instanceQuantum=<
  QUANTUM>,licenseInfo.instanceLowWatermark=<LOW WATERMARK>,
  licenseInfo.bandwidthPlatinumQuantum=<QUANTUM-in-Mbps>,
  licenseInfo.bandwidthPlatinumLowWatermark=<LOW WATERMARK-in-Mbps
  >
```

For enterprise bandwidth edition:

```
1 helm install my-release citrix/cpx-license-aggregator --set
  licenseServer.address=<License-Server-IP-or-FQDN>,redis.
  secretName=<Kubernetes-Secret-for-DB-password>,licenseAggregator
  .username=<unique-ID-for-CLA>,licenseInfo.instanceQuantum=<
  QUANTUM>,licenseInfo.instanceLowWatermark=<LOW WATERMARK>,
  licenseInfo.bandwidthEnterpriseQuantum=<QUANTUM-in-Mbps>,
  licenseInfo.bandwidthEnterpriseLowWatermark=<LOW WATERMARK-in-
  Mbps>
```

For standard bandwidth edition:

```
1 helm install my-release citrix/cpx-license-aggregator --set
  licenseServer.address=<License-Server-IP-or-FQDN>,redis.
  secretName=<Kubernetes-Secret-for-DB-password>,licenseAggregator
  .username=<unique-ID-for-CLA>,licenseInfo.instanceQuantum=<
  QUANTUM>,licenseInfo.instanceLowWatermark=<LOW WATERMARK>,
  licenseInfo.bandwidthStandardQuantum=<QUANTUM-in-Mbps>,
  licenseInfo.bandwidthStandardLowWatermark=<LOW WATERMARK-in-Mbps
  >
```

These commands deploy the NetScaler CPX License Aggregator on the Kubernetes cluster with the default configuration. You can configure the parameters at the time of installation. For more information, see the **NetScaler CPX License Aggregator configuration** section in the [Helm chart GitHub repository](#) that lists the mandatory and optional parameters that you can configure during installation.

Installing NetScaler CPX License Aggregator to manage vCPU Licenses

Use one of the following commands depending on the type of NetScaler CPX vCPU license that you have. In these commands, `my-release` is used as the release name.

Note:

By default, the Helm chart installs the recommended RBAC roles and role bindings.

For platinum vCPU edition:

```
1 helm install my-release citrix/cpx-license-aggregator --set
  licenseServer.address=<License-Server-IP-or-FQDN>,redis.
  secretName=<Kubernetes-Secret-for-DB-password>,licenseAggregator
  .username=<unique-ID-for-CLA>,licenseInfo.vcpuPlatinumQuantum=<
  QUANTUM>,licenseInfo.vcpuPlatinumLowWatermark=<LOW WATERMARK>
```

For enterprise vCPU edition:

```
1 helm install my-release citrix/cpx-license-aggregator --set
  licenseServer.address=<License-Server-IP-or-FQDN>,redis.
  secretName=<Kubernetes-Secret-for-DB-password>,licenseAggregator
  .username=<unique-ID-for-CLA>,licenseInfo.vcpuEnterpriseQuantum
  =<QUANTUM>,licenseInfo.vcpuEnterpriseLowWatermark=<LOW WATERMARK
  >
```

For standard vCPU edition:

```
1 helm install my-release citrix/cpx-license-aggregator --set
  licenseServer.address=<License-Server-IP-or-FQDN>,redis.
  secretName=<Kubernetes-Secret-for-DB-password>,licenseAggregator
  .username=<unique-ID-for-CLA>,licenseInfo.vcpuStandardQuantum=<
  QUANTUM>,licenseInfo.vcpuStandardLowWatermark=<LOW WATERMARK>
```

Installing NetScaler CPX License Aggregator to manage multiple licenses

If you need NetScaler CPX license aggregator to manage multiple types of licenses, then the relevant arguments of those licenses must be specified in the Helm command.

For example:

To deploy NetScaler CPX License Aggregator for `pooled platinum bandwidth edition` and `vCPU platinum edition` licenses:

```
1 helm install demo citrix/cpx-license-aggregator --set
  licenseServer.address=<License-Server-IP-or-FQDN>,redis.
  secretName=<Kubernetes-Secret-for-DB-password>,
  licenseAggregator.username=<unique-ID-for-CLA>,licenseInfo.
  instanceQuantum=<QUANTUM>,licenseInfo.instanceLowWatermark=<
  LOW WATERMARK>,licenseInfo.bandwidthPlatinumQuantum=<QUANTUM-
  in-Mbps>,licenseInfo.bandwidthPlatinumLowWatermark=<LOW
  WATERMARK-in-Mbps>,licenseInfo.vcpuPlatinumQuantum=<QUANTUM>,
  licenseInfo.vcpuPlatinumLowWatermark=LOW WATERMARK>
```

Configuring NetScaler CPX to get license from NetScaler CPX License Aggregator

When you use NetScaler CPX License Aggregator for licensing NetScaler CPX, the environment variable `CLA` need to be provided in the NetScaler CPX deployment YAML.

The `ipaddress` or `domainname` using which NetScaler CPX License Aggregator can be accessed must be provided in this environment variable as follows:

```
1   env:
2     - name: "CLA"
3       value: "192.0.2.2"
```

Or

```
1   env:
2     - name: "CLA"
3       value: "local-cla.org"
```

You must provide the following environment variables as well in the NetScaler CPX YAML.

- `POD_NAME`: Specifies the name of the pod. The name of the pod is exposed to NetScaler CPX as an environment variable.
- `POD_NAMESPACE`: Specifies the namespace of the pod. The namespace of the pod is exposed to NetScaler CPX as an environment variable.
- `Bandwidth`: Specifies the bandwidth in Mbps for allocating to NetScaler CPX.
- `Edition`: Specifies the license edition. The supported values include Standard, Platinum, and Enterprise.
- `CPX_CORES`: Specifies the number of cores that you want to run for NetScaler CPX.

For more information on different NetScaler CPX licensing options, see [NetScaler CPX licensing](#).

The following shows a sample configuration with these environment variables:

```
1     - name: POD_NAME
2       valueFrom:
3         fieldRef:
4           apiVersion: v1
5           fieldPath: metadata.name
6     - name: POD_NAMESPACE
7       valueFrom:
8         fieldRef:
9           apiVersion: v1
10          fieldPath: metadata.namespace
11     - name: "BANDWIDTH"
12       value: 1000
13     - name: "CPX_CORES"
14       value: 1
15     - name: "EDITION"
16       value: PLATINUM
```

You also need to add the following label to the NetScaler CPX YAML:

```
1     labels:
2     adc: citrix
```

For a sample deployment of NetScaler CPX License Aggregator, see [NetScaler CPX License Aggregator: Sample deployment](#).

Configuring NetScaler CPX

December 27, 2023

You can configure a NetScaler CPX instance by accessing the CLI prompt through the Linux Docker host, or by using the NetScaler NITRO APIs.

Configuring a NetScaler CPX Instance by Using the Command Line Interface

Access the Docker host and log on to the SSH prompt of the instance as shown in the following figure. The default administrator credentials to log on to a NetScaler CPX instance are root/linux.

```
root@ubuntu:~# ssh -p 32777 root@127.0.0.1
root@127.0.0.1's password:
Welcome to Ubuntu 14.04.3 LTS (GNU/Linux 3.19.0-25-generic x86_64)

 * Documentation:  https://help.ubuntu.com/
Last login: Tue Dec 15 02:45:42 2015 from 172.17.0.1
root@10:~#
```

Type the following command to use the command line prompt of the instance to run CLI commands:
cli_script.sh "<command>"

Example:

```
root@10:~# cli_script.sh "show ip"
exec: show ip
      Ipaddress      Traffic Domain  Type
      -----      -
1)      172.17.0.4      0      NetScaler IP|VIP
2)      192.0.0.1      0      SNIP
```

To log out of the instance prompt, type **logout**.

Support for using a non-default password in NetScaler CPX

NetScaler CPX supports using a non-default password for the root account, that is `nsroot`. A default password is generated and assigned to the user once NetScaler CPX has been deployed. This default password is also updated for SSH users: `root` and `nsroot`. You can change this default password manually. You can also reset the default SSH password for `root` and `nsroot` user accounts manually. Citrix recommends changing this password manually to preserve the security of the system.

Once you reset your password, the new password is used for NITRO API communications and `cli_script.sh` executions.

The default root account password is stored in plain text in the `/var/deviceinfo/random_id` file in the NetScaler CPX file system.

Use the following syntax for running `cli_script.sh` with the credentials:

```
cli_script.sh "<command>"":<user>:<password>"
```

For example, to run `cli_script.sh` for displaying IP addresses with user `nsroot` and password `Citrix123`, use the following:

```
1 cli_script.sh "show ns ip" ":nsroot:Citrix123"
```

Configuring a NetScaler CPX Instance by Using the NITRO API

You can use the NetScaler NITRO API to configure NetScaler CPX instances.

To configure NetScaler CPX instances by using the Nitro API, in a web browser, type:

```
http://<host_IP_address>:<port>/nitro/v1/config/<resource-type>
```

To retrieve statistics by using the Nitro API, in a web browser, type:

```
http://\<host\_IP\_address>:\<port>/nitro/v1/stat/\<resource-type>\
```

For more information about using the NITRO API, see [REST Web Services](#). For NetScaler CPX, use `CPX IP address:port` where `netScaler-ip-address` is mentioned.

Configuring a NetScaler CPX Instance by Using Jobs

You can configure NetScaler CPX instances by creating and running jobs in NetScaler ADM. You can use the configurations from configuration templates, extract configurations available on other devices, and use configurations saved in text files. You can also record configurations done by using the configuration utility of another instances. NetScaler ADM then displays the corresponding CLI commands

for you to use on your NetScaler CPX instance. After you select the configuration, you must then select **NetScaler CPX instances** on which you want to load the configuration, specify the variable values, and run the job.

To configure NetScaler CPX instances by using Jobs:

1. Log on to NetScaler ADM by using the administrative credentials.
2. Navigate to **Networks > Configuration Jobs**, and then click **Create Job**.
3. Specify the required values, and select the configuration source. You can also type the commands you want to run.

Select Configuration

Select Instances

Specify Variable Values

Configuring AppFlow on a NetScaler CPX instance

October 17, 2023

You can configure AppFlow feature on a NetScaler CPX instance to collect webpage performance data, flow and user-session level information, and database information required for application performance monitoring and analytics. These data records are sent to NetScaler ADM where you can view real-time and historical reports for all your applications.

To configure AppFlow, first, you must enable the AppFlow feature. Then, you specify the collectors to which the flow records are sent. After that, you define actions, which are sets of configured collectors. Then you configure one or more policies and associate an action to each policy. The policy tells the NetScaler CPX to select requests the flow records of which are sent to the associated action. Finally, you bind each policy either globally or to the specific virtual server to put it into effect.

You can further set AppFlow parameters to specify the template refresh interval and to enable the exporting of [httpURL](#), [httpCookie](#), and [httpReferer](#) information. On each collector, you must specify the NetScaler CPX IP address as the address of the exporter.

The configuration utility provides tools that help users define the policies and actions. It determines exactly how the NetScaler CPX export records for a particular flow to a set of collectors(action.) The command line interface provides a corresponding set of CLI-based commands for experienced users who prefer a command line.

Before you can monitor the records, you must add the NetScaler CPX instance to the NetScaler ADM. For more information about adding a NetScaler CPX instance to NetScaler ADM, see [Installing a NetScaler CPX Instance by Using NetScaler ADM](#).

Enable AppFlow

To use the AppFlow feature, you must first enable it.

To enable the AppFlow feature by using the command line interface:

Run the following commands:

```
1 enable ns feature AppFlow
2 enable ns mode ulfd
```

Specify a Collector

A collector receives AppFlow records generated by the NetScaler. To send the AppFlow records, you must specify at least one collector. By default, the collector listens to IPFIX messages on UDP port 4739. You can change the default port, when configuring the collector.

To specify a collector by using the command line interface:

Use the following commands to add a collector:

```
1 add appflow collector <name> -IPAddress <ipaddress> -port <port_number>
  -netprofile <netprofile_name> -Transport Logstream
```

To verify the configuration, use the following command:

```
1 show appflow collector <name>
```

To specify multiple collectors by using the command line interface:

Use the following commands to add and send the same data to multiple collectors:

```
1 add appflow collector <collector1> -IPAddress <IP> -Transport Logstream
2
3 add appflow collector <collector2> -IPAddress <IP> -Transport Logstream
4
5 add appflow action <action> -collectors <collector1> <collector2> -
  Transport Logstream
6
7 add appflow policy <policy> true <action> -Transport Logstream
8
9 bind lbvserver <lbvserver> -policy <policy> -priority <priority> -
  Transport Logstream
```

Configuring an AppFlow Action

An AppFlow action is a set collector, to which the flow records are sent if the associated AppFlow policy matches.

Use the following commands to configure an AppFlow action:

```
1 add appflow action <name> --collectors <string> ... \[-
  clientSideMeasurements \((Enabled|Disabled) \) \[-comment <string>]
```

To verify the configuration, use the following command:

```
1 show appflow action
```

Configuring an AppFlow Policy

After you configure an AppFlow action, you must next configure an AppFlow policy. An AppFlow policy is based on a rule, which consists of one or more expressions.

To configure an AppFlow policy by using the command line interface:

At the command prompt, type the following command to add an AppFlow policy and verify the configuration:

```
1 add appflow policy <name> <rule> <action>
2
3 show appflow policy <name>
```

Binding an AppFlow Policy

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler CPX.

To globally bind an AppFlow policy by using the command line interface:

Use the following command to globally bind an AppFlow policy:

```
1 bind appflow global <policyName> <priority> [<gotoPriorityExpression [-
  type <type>] [-invoke (<labelType> <labelName>)]
```

Verify the configuration using the following command:

```
1 show appflow global
```

Configuring NetScaler CPX Using a Configuration File

October 17, 2023

Instead of using command line interface (`cli_script.sh`), NITRO API, or NetScaler ADM configuration jobs to configure the NetScaler CPX, you can configure the NetScaler CPX using a static configuration file while deploying the NetScaler CPX instance.

You can provide a static configuration file as an input file while deploying the NetScaler CPX container. During NetScaler CPX container startup, the container is configured based on the configuration specified in the static configuration file. This configuration includes NetScaler-specific configuration and bash shell commands that you can dynamically run on the NetScaler CPX container.

Structure of the static configuration file

As mentioned earlier, when NetScaler CPX is deployed, it is configured based on the configurations specified in the static configuration file.

The static configuration file is a `.conf` file that includes two tags, `#NetScaler Commands` and `#Shell Commands`. Under the `#NetScaler Commands` tag, you must add all the NetScaler commands to configure NetScaler-specific configuration on NetScaler CPX. Under the `#Shell Commands` tag, you must add the shell commands that you want to run on NetScaler CPX.

During the NetScaler CPX container deployment, the NetScaler commands and shell commands are run on the container in the order specified in the configuration file.

Important:

- The tags can be repeated multiple times in the configuration file.
- The tags are not case-sensitive.
- The configuration file must be present in the `/etc` directory as `cpx.conf` file in the container's file system.
- The configuration file can also include comments. You must add a `#` character before your comments.
- If there are failure scenarios while deploying the NetScaler CPX container with the configuration file, the failures are logged in the `ns.log` file in the container.
- When you reboot the NetScaler CPX container the configuration file is reapplied on the container.

```
1 #NetScaler Commands
2
3 add lb vserver v1 http 1.1.1.1 80
4
5 add service s1 2.2.2.2 http 80
6
7 bind lb vserver v1 s1
8
9 #Shell Commands
10
11 touch /etc/a.txt
12
13 echo "this is a" > /etc/a.txt
14
15 #NetScaler Commands
16
17 add lb vserver v2 http
18
19 #Shell Commands
20
21 echo "this is a 1" >> /etc/a.txt
22
23 #NetScaler Commands
24
25 add lb vserver v3 http
26
27 #This is a test configuration file
28 <!--NeedCopy-->
```

To install a NetScaler CPX container and to dynamically configure the NetScaler CPX container based on a configuration file, mount the static configuration file using the `-v` option in the `docker run` command:

```
1 docker run -dt --privileged=true -e EULA=yes --ulimit core=-1 -v /tmp/  
  cpx.conf:/etc/cpx.conf --name mycpx store/citrix/citrixadccpx:13.0-x  
  .x  
2 <!--NeedCopy-->
```

Dynamic Routing support in NetScaler CPX

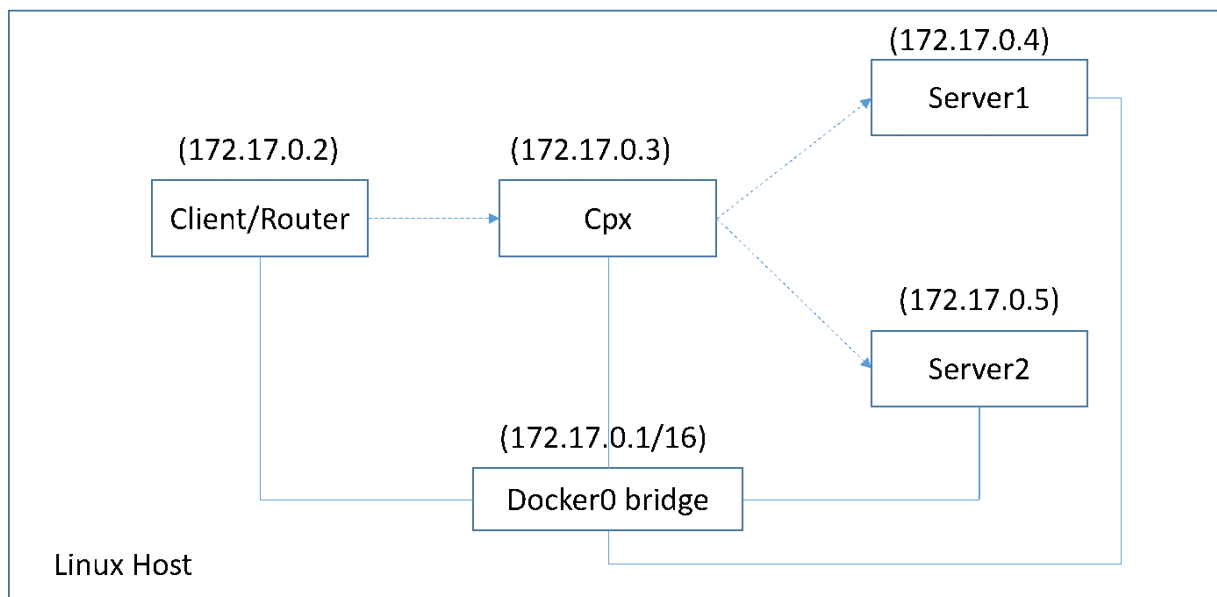

November 2, 2023

NetScaler CPX supports the BGP dynamic routing protocol. The key objective of the dynamic routing protocol is to advertise the virtual server's IP address based on the health of the services, bound to the virtual server. It helps an upstream router to choose the best among multiple routes to a topographically distributed virtual server.

For information about the non-default password in NetScaler CPX, see the [Support for using a non-default password in NetScaler CPX](#) section in the [Configuring NetScaler CPX](#) document.

In a single host network, the client, the servers, and the NetScaler CPX instance are deployed as containers on the same Docker host. All the containers are connected through the docker0 bridge. In this environment, the NetScaler CPX instance acts as a proxy for the applications provisioned as containers on the same Docker host. For information about NetScaler CPX host networking mode deployment, see [Host networking mode](#).

The following figure illustrates the single host topology.

In this topology, virtual servers are configured and advertised (based on the health of services) to the upstream network or router using BGP.

Perform the following steps to configure BGP on NetScaler CPX in single Docker host with the bridge-networking mode.

Configure BGP based Route Health Injection using REST API on NetScaler CPX

1. Create a container from the NetScaler CPX image using the following command:

```
1 docker run -dt --privileged=true -p 22 -p 80 -p 161 -e EULA=yes --  
  ulimit core=-1 cpx: <tag>
```

For example:

```
1 docker run -dt --privileged=true -p 22 -p 80 -p 161 -e EULA=yes --  
  ulimit core=-1 cpx:12.1-50.16
```

2. Log in to the container using the following command:

```
1 docker exec -it <container id> bash
```

3. Enable the BGP feature using the following command:

```
1 cli_script.sh "enable ns feature bgp"
```

4. Obtain the NSIP using the `show ns ip` command:

```
1 cli_script.sh "show ns ip"
```

5. Add the virtual server using the following command:

```
1 cli_script.sh "add lb vsrver <vsrver_name> http <VIP> <PORT>"
```

6. Add services and bind services to the virtual server.

7. Enable `hostroute` for the VIP using the following command:

```
1 cli_script.sh "set ns ip <VIP> -hostroute enabled "
```

Log out from the container and send BGP NITRO commands from the host to the NSIP on the port 9080.

8. Configure the BGP router:

For example, if you want to configure:

```
1 router bgp 100  
2 Neighbour 172.17.0.2 remote-as 101  
3 Redistribute kernel
```

Specify the command as the following:

```

1  curl -u username:password http://<NSIP>:9080/nitro/v1/config/ -X
    POST --data 'object={
2  "routerDynamicRouting": {
3  "bgpRouter" : {
4  "localAS":100, "neighbor": [{
5  "address": "172.17.0.2", "remoteAS": 101 }
6  ], "afParams":{
7  "addressFamily": "ipv4", "redistribute": {
8  "protocol": "kernel" }
9  }
10 }
11 }
12 }
13 '
```

9. Install the learnt BGP routes into the PE using the following NITRO command:

```

1  curl -u username:password http://<NSIP>:9080/nitro/v1/config/ --
    data 'object={
2  "params":{
3  "action":"apply" }
4  ,"routerDynamicRouting": {
5  "commandstring" : "ns route-install bgp" }
6  }
7  '
```

10. Verify the BGP adjacency state using the following NITRO command:

```

1  curl -u username:password http://<NSIP>:9080/nitro/v1/config/
    routerDynamicRouting/bgpRouter
```

Sample output:

```

1  root@ubuntu:~# curl -u username:password http://172.17.0.3:9080/
    nitro/v1/config/routerDynamicRouting/bgpRouter
2  {
3  "errorcode": 0, "message": "Done", "severity": "NONE", "
    routerDynamicRouting":{
4  "bgpRouter":[{
5  "localAS": 100, "routerId": "172.17.0.3", "afParams": [ {
6  "addressFamily": "ipv4" }
7  , {
8  "addressFamily": "ipv6" }
9  ], "neighbor": [ {
10 "address": "172.17.0.2", "remoteAS": 101, "ASOriginationInterval
    ": 15, "advertisementInterval": 30, "holdTimer": 90, "
    keepaliveTimer": 30, "state": "Connect", "singlehopBfd":
    false, "multihopBfd": false, "afParams": [ {
11 "addressFamily": "ipv4", "activate": true }
12 , {
13 "addressFamily": "ipv6", "activate": false }
```

```
14 ]
```

11. Verify that the routes learnt through BGP are installed in the packet engine with the following command:

```
1 cli_script.sh "show route"
```

12. Save the configuration using the following command:

```
1 cli_script.sh "save config"
```

The dynamic routing configuration is saved in the `/nsconfig/ZebOS.conf` file.

Configuring high availability for NetScaler CPX

November 2, 2023

A system with mission-critical and business-critical applications must be continuously available without having single-points-of failure. Systems with high availability ensure the continuous availability of applications without any disruption to services provided for the user. NetScaler CPX supports high availability deployment of two NetScaler instances which protects the services from unplanned downtime and ensures business continuity in the event of a failure. Once you configure high availability, you can also upgrade the NetScaler CPX software without causing any disruption of services to the users.

Note:

If the internal user account is disabled, high availability for NetScaler CPX feature is not supported.

Topology 1: Deploy NetScaler CPX instances on a single Docker host with bridge networking mode

In this topology, two NetScaler CPX nodes are created on the same Docker host with bridge networking mode. Both nodes are on the same bridge network and nodes are directly reachable to each other.

The following diagram explains this topology.

In this example two NetScaler CPX instances, CPX-1 (NSIP: 172.17.0.3) and CPX-2 (NSIP: 172.17.0.4), are created on the same Docker host. For high availability support, you must configure high availability nodes on both NetScaler CPX instances using the NSIP of the other node.

Perform the following steps to configure high availability support on NetScaler CPX instances on a single docker host in bridge mode.

1. Access the Docker host and log on to the SSH prompt of the NetScaler CPX instance. For more information, see [Configuring a NetScaler CPX Instance by Using the Command Line Interface](#).
2. Configure a high availability node on CPX-1 instance by using the following command.

```
1 cli_script.sh 'add ha node 1 172.17.0.4 [-inc enabled]'
```

3. Configure a high availability node on CPX-2 instance by using the following command.

```
1 cli_script.sh 'add ha node 1 172.17.0.3 [-inc enabled]'
```

Note:

When a NetScaler CPX node in bridge networking mode is restarted, the IP address assigned to a NetScaler CPX might change depending on the docker version on host. If the NSIP of either of the nodes change after restarting a NetScaler CPX, the existing high availability configuration will not work even though the configuration is saved. In that case, you must configure high availability on NetScaler CPX nodes again.

Topology 2: Deploy NetScaler CPXs on different Docker hosts with bridge networking mode

In this topology, two NetScaler CPX instances are deployed in bridge mode on two different docker hosts which are reachable from each other. In this deployment, NetScaler CPX must be aware of the

IP address of the host. The **HOST** environment variable can be used at the time of provisioning the NetScaler CPX to make NetScaler CPX aware of the IP address of the host.

You must set port mapping for NetScaler CPX nodes. You can use the **-p** option of the **docker run** command while creating the NetScaler CPX node to enable port mapping for the required ports.

You must map the following ports:

- UDP 3003
- TCP 3008
- TCP 8873

The following diagram explains the topology of deploying two NetScaler CPX instances in bridge mode on two different docker hosts.

In this diagram, straight blue line represents flow of CPX-HA traffic between two hosts.

Note: On a Docker host, only one NetScaler CPX can form a high availability pair. Any other NetScaler CPX on the same host cannot form a high availability pair with another NetScaler CPX on a different host.

Perform the following steps to deploy NetScaler instances in bridge mode on different docker hosts and configure high availability support using the sample topology.

In this example, host1 IP address is configured as 10.10.10.10/24 and host2 IP address is configured as 10.10.10.20/24.

1. Deploy NetScaler CPX with the required port-mapping on host1 using the following command.

```
1 Docker run -dt --privileged=true -e EULA=yes --ulimit core=-1 -p
8873:8873 -p 3003:3003/udp -p 3008:3008 -e Host=10.10.10.10 cpx
:latest
```

2. Deploy NetScaler CPX on host2 using the same command with IP address of host 2.

```
1 docker run -dt --privileged=true -e EULA=yes --ulimit core=-1 -p
  8873:8873 -p 3003:3003/udp -p 3008:3008 -e HOST=10.10.10.20 cpx
  :latest
```

3. Configure a high availability node on CPX-1 instance by using the following command.

```
1 cli_script.sh 'add ha node 1 10.10.10.20 -inc enabled'
```

4. Configure a high availability node on CPX-2 instance by using the following command.

```
1 cli_script.sh 'add ha node 1 10.10.10.10 -inc enabled'
```

Note: In this deployment, you must use the host IP address of the high availability node instead of the NSIP address of the high availability node.

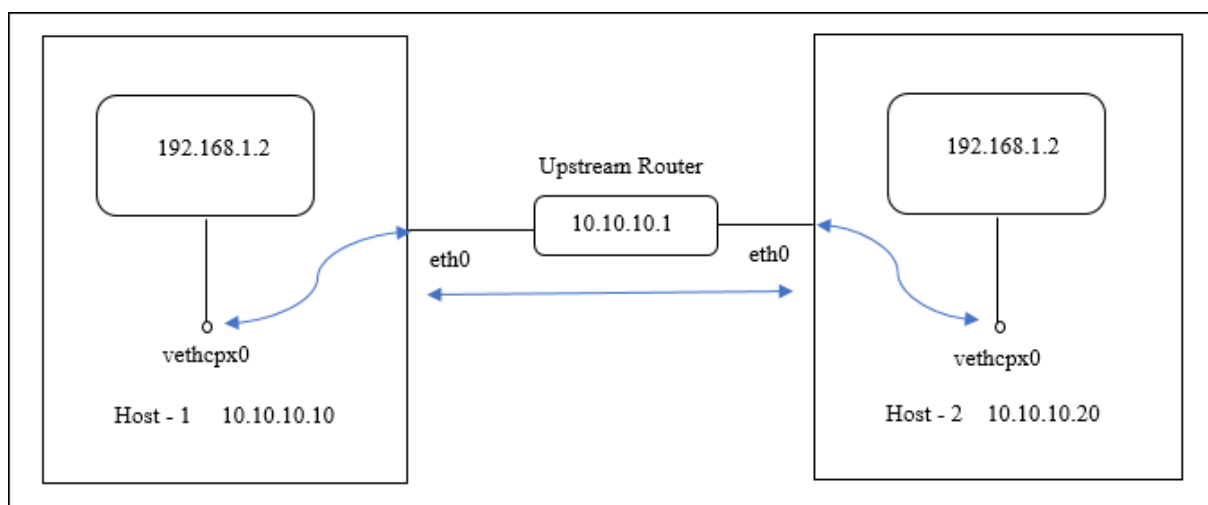

Topology 3: Deploy NetScaler CPXs on different Docker hosts in host networking mode without a dedicated Interface

In this topology, two NetScaler CPX instances are deployed on two different Docker hosts in host mode without a dedicated interface. The hosts must be reachable to each other.

In this deployment, NetScaler CPX must be aware of the IP address of the host. You can use the **HOST** environment variable during the provisioning of NetScaler CPX to make it aware of the IP address of the host.

You must set port mapping for NetScaler CPX node. You can use the -p option of the **docker run** command while creating the NetScaler CPX node to enable port mapping for the required ports.

The following diagram explains the topology.

In this diagram, straight blue line represents flow of CPX-HA traffic between two hosts.

Note: On a Docker host, you can deploy only one host-mode NetScaler CPX.

Perform the following steps to deploy the NetScaler CPX instances and configure high availability support using the sample topology.

1. Deploy NetScaler CPX with the required port-mapping and on host1 using the following command.

```
1 docker run -dt --privileged=true -e EULA=yes --ulimit core=-1 --net=host -e NS_NETMODE=HOST -e HOST=10.10.10.10 cpx:latest
```

2. Deploy NetScaler CPX on host2 with the IP address of host2 using the following command.

```
1 docker run -dt --privileged=true -e EULA=yes --ulimit core=-1
2 --net=host -e NS_NETMODE=HOST -e HOST=10.10.10.20 cpx:latest
```

3. Configure a high availability node on CPX-1 instance by using the following command.

```
1 cli_script.sh 'add ha node 1 10.10.10.20 -inc enabled'
```

4. Configure a high availability node on CPX-2 instance by using the following command.

```
1 cli_script.sh 'add ha node 1 10.10.10.10 -inc enabled'
```

Topology 4: Deploy CPXs on different Docker hosts with host networking mode and dedicated interfaces

In this topology, two NetScaler CPX instances are deployed on different Docker hosts in host networking mode. The hosts must have more than one interface. You can specify the dedicated interface for NetScaler CPX by using the **CPX_NW_DEV** environment variable.

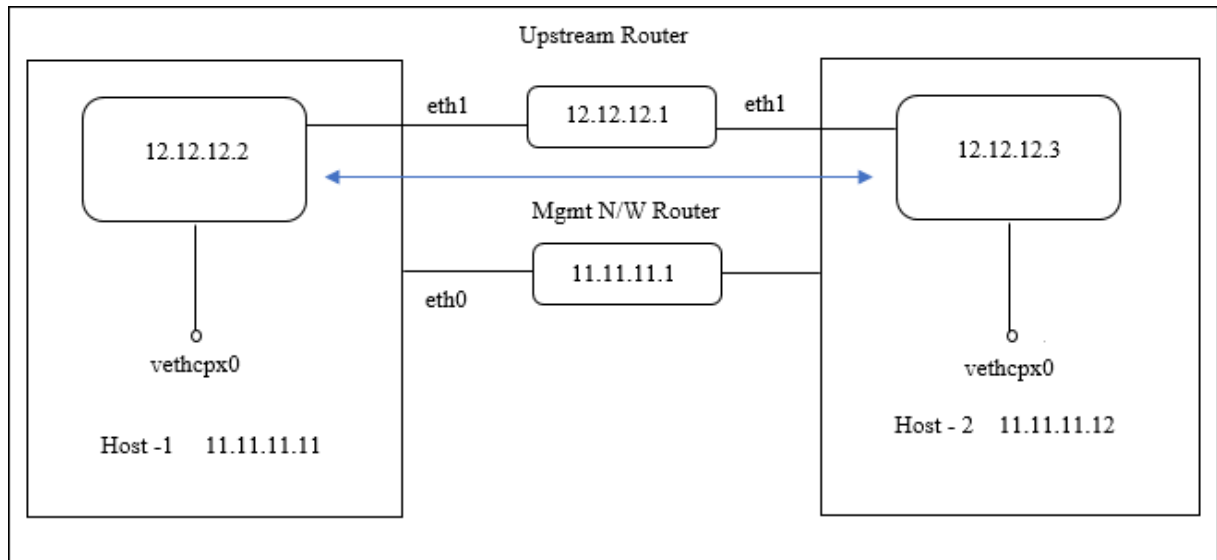

For more information on assigning dedicated network interfaces for NetScaler CPX using the CPX_NW_DEV environment variable, see [Deploying the NetScaler CPX Instance Using the docker run Command](#).

NetScaler CPXs deployed on different Docker hosts must be reachable to each other on this data network with the dedicated interface.

This configuration allows high availability nodes to exchange heartbeat messages and synchronize configuration files by directly communicating on ports 3003, 3008, and 8873. There is no need for NAT rules on host. The default NSIP of NetScaler CPX created in host mode is same on both nodes. So, you must also specify the **NS_IP** and **NS_GATEWAY** information.

In this example, two host-mode NetScaler CPXs are created on two different hosts. NetScaler CPX instances own the **eth1** interfaces on both hosts and **eth1** interfaces are connected to the same network.

The following diagram explains the topology. In this diagram, blue arrow represents the flow of CPX-HA traffic on the network connected to the eth1 interface.

Note: On a Docker host, you can only deploy one host-mode NetScaler CPX.

Perform the following steps to deploy the NetScaler CPX instances and configure high availability support using the sample topology.

1. Deploy NetScaler CPX in host mode on host1 using the following command.

```
1 docker run -dt --privileged=true --net=host -e NS_NETMODE="HOST" -e CPX_NW_DEV=eth1 -e NS_IP='12.12.12.2' -e NS_GATEWAY='12.12.12.9' -e EULA=yes --ulimit core=-1 cpx:latest
```

2. Deploy NetScaler CPX in host mode on host2 using the following command.

```
1 docker run -dt --privileged=true --net=host -e NS_NETMODE="HOST" -e CPX_NW_DEV=eth1 -e NS_IP='12.12.12.3' -e NS_GATEWAY='12.12.12.10' -e EULA=yes --ulimit core=-1 cpx:latest
```

Note: You must configure static routes for both NetScaler CPX nodes to reach the other NetScaler CPX node for exchanging heartbeat messages and synchronizing configuration files.

3. Configure a high availability node on CPX-1 instance by using the following command.

```
1 cli_script.sh 'add ha node 1 12.12.12.3 [-inc enabled]'
```

4. Configure a high availability node on CPX-2 instance by using the following command.

```
1 cli_script.sh 'add high availability node 1 12.12.12.2 [-inc enabled]'
```

Configuring Docker Logging Drivers

October 17, 2023

Docker includes logging mechanisms called “logging drivers” to help you get information from the running containers. You can configure a NetScaler CPX container to forward logs that it generates to the docker logging drivers. For more information on docker logging drivers, see [Configure logging drivers](#).

By default, all logs generated by the NetScaler CPX container are stored in `/cpx/log/ns.log` file on the docker host. When you start the NetScaler CPX container using the docker run command, you can configure it to forward all the generated logs to a docker logging driver using the `--log-driver` option. If the logging driver has configurable parameters, you can set them using the `--log-opt <NAME>=<VALUE>` option.

In the following example, the NetScaler CPX container is configured to forward all the generated logs using syslog as logging driver.

```
1 docker run -dt --privileged=true --log-driver syslog --log-opt syslog-  
    address=udp://10.106.102.190:514 -e EULA=yes --ulimit core=-1 --name  
    test store/citrix/cpx:12.1-48.13  
2 <!--NeedCopy-->
```

Similarly, in the following example the NetScaler CPX container is configured to forward all the generated logs using Splunk as logging driver.

```
1 docker run -dt --privileged=true --log-driver=splunk --log-opt splunk-  
    token=176FCEBF-4CF5-4EDF-91BC-703796522D20 --log-opt splunk-url=  
    https://splunkhost:8088 -e EULA=yes --ulimit core=-1 --name test  
    store/citrix/cpx:12.1-48.13  
2 <!--NeedCopy-->
```

Upgrading a NetScaler CPX Instance

November 2, 2023

You can upgrade a NetScaler CPX instance by shutting it down, installing the latest version on the same mount point, and then deleting the old instance. A mount point is a directory into which you mount the `/cpx` directory on the host.

For example, to mount the `/cpx` directory of the existing NetScaler CPX instance in the host's `/var/cpx` directory, the mount point is `/var/cpx` and the NetScaler CPX mount directory is `/cpx` as shown below:

```

1 root@ubuntu:~# docker run -dt -e EULA=yes --name mycpx -v /var/cpx
   :/cpx --ulimit core=-1 cpx:13.0-x.x
2 <!--NeedCopy-->

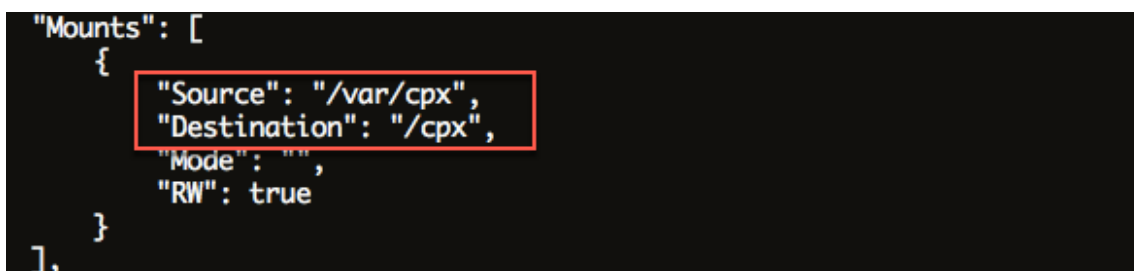

```

Prerequisites

Ensure that you have:

- Details of the host directory in which you mounted the existing NetScaler CPX instance's /cpx directory. You can use the `docker inspect <containerName>` command, where `<containerName>` is the name of the NetScaler CPX container, to display information about the host directory.

The output of the command provides the details of the container configurations, including the volumes. In the “**Mounts**” entry, the “**Source**” subentry shows the location of the host directory on the host.

```

"Mounts": [
  {
    "Source": "/var/cpx",
    "Destination": "/cpx",
    "Mode": "",
    "RW": true
  }
],

```

- Download the latest NetScaler CPX Docker image file and load the NetScaler CPX Docker image. To load the image, navigate to the directory in which you saved the Docker image file. Use the `docker load -i <image_name>` command to load the image. After the NetScaler CPX image is loaded, you can enter the `docker images` command to display information about the image:

```

1 root@ubuntu:~# docker load -i cpx-13.0-x.x.gz
2
3 root@ubuntu:~# docker images
4
5 REPOSITORY TAG IMAGE ID CREATED VIRTUAL SIZE
6
7 cpx 13.0-x.x 2e97aadf918b 43 hours ago 414.5 MB
8 <!--NeedCopy-->

```

To upgrade a NetScaler CPX instance

1. Stop the existing NetScaler CPX instance by entering the `docker stop <containerName>` command, where `<containerName>` is the name of the NetScaler CPX instance.

```

1 root@ubuntu:~# docker stop mycpx
2 mycpx
3 <!--NeedCopy-->

```

2. Using the `docker run` command, deploy the latest NetScaler CPX instance from the NetScaler CPX image that you loaded onto the host. Ensure that you deploy the instance at the same mount point (for example, `/var/cpx:/cpx`) that you used for the existing NetScaler CPX instance.

```

1 root@ubuntu:~# docker run -dt -P -e CPX_CORES=1 --name latestcpx
  --ulimit core=-1 -e EULA=yes -v /var/cpx:/cpx --cap-add=
  NET_ADMIN cpx:13.0-x.x
2 <!--NeedCopy-->

```

You can enter the `docker ps` command so that you can verify that the deployed NetScaler CPX instance is the latest version.

```

1 ```
2   root@ubuntu:~# docker ps
3
4   CONTAINER ID      IMAGE          COMMAND          PORTS
5   CREATED          STATUS        NAMES
6   ead12ec4e965      cpx:13.0-x.x  "/bin/sh -c 'bash -C "  5
7   seconds ago      Up 5 seconds  22/tcp, 80/tcp, 443/
  tcp, 161/udp      latestcpx
8 <!--NeedCopy--> ```

```

3. After verifying that you deployed the correct NetScaler CPX instance, enter the `docker rm <containerName>` command to delete the older instance.

```

1 root@ubuntu:~# docker rm mycpx
2 mycpx
3 <!--NeedCopy-->

```

Using Wildcard Virtual Servers in NetScaler CPX Instance

October 17, 2023

When you provision a NetScaler instance, only one private IP address (single IP address) is assigned to a NetScaler CPX instance by the Docker engine. The three IP functions of a NetScaler instance are multiplexed onto one IP address. This single IP address uses different port numbers to function as the NSIP, SNIP, and VIPs.

The single IP address that is assigned by the Docker engine is dynamic. Add the Load Balancing (LB) or Content Switching (CS) virtual servers using the single IP address or using the 127.0.0.1 IP address. The virtual servers created using 127.0.0.1 is called as Wildcard Virtual Servers. By default, when you create a wildcard virtual server, the NetScaler CPX replaces the assigned IP address of the wildcard virtual server. The assigned IP address is 127.0.0.1, which is replaced with the NSIP assigned to the NetScaler CPX instance by the Docker engine.

In high availability NetScaler CPX deployments, you can add wildcard virtual servers on the primary NetScaler CPX instance. The configuration sync between nodes configures the wildcard virtual server on the secondary NetScaler CPX instance. It eliminates the need for configuring the virtual server on the NSIP assigned by the Docker engine to the NetScaler CPX instances.

Points to Note:

- Ensure that the port number that you assign to the wildcard virtual server is not used by any other virtual server in the deployment.
- Wildcard virtual server addition fails if the port number that you assign to the wildcard virtual server is already in use by the internal services.
- The wildcard virtual server does not support the * character.

To create a wildcard load balancing virtual server, at the command prompt, enter the following command:

```
1      add lb vsrver <name> <serviceType> 127.0.0.1 <port>
2
3      add lb vsrver testlbvsrver HTTP 127.0.0.1 30000
4 <!--NeedCopy-->
```

To create a wildcard content switching virtual server, at the command prompt, enter the following command:

```
1      add cs vsrver <name> <serviceType> 127.0.0.1 <port>
2
3      add cs vsrver testcsvsrrver HTTP 127.0.0.1 30000
4 <!--NeedCopy-->
```

Deploy NetScaler CPX as a Proxy to Enable East-West Traffic Flow

October 17, 2023

In this deployment, the NetScaler CPX instance acts as a proxy to enable communication between application containers residing on multiple hosts. The NetScaler CPX instance is provisioned along with the applications in multiple hosts and provides the shortest path for communication.

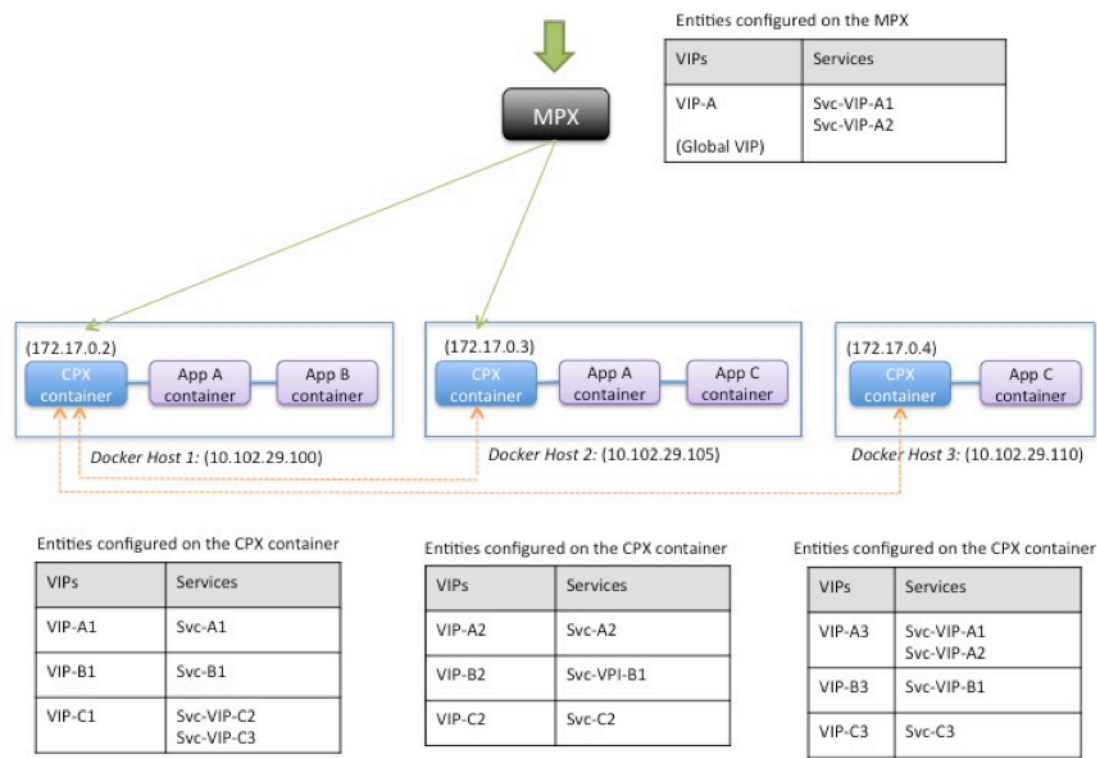

The following image illustrates traffic flow between two applications through the NetScaler CPX instances.

This image shows traffic flow between application C and application B and between application A and application B. When app C (in any of the hosts) sends a request to B, the request is first received on the NetScaler CPX container on the same host as app C. Then, the NetScaler CPX container passes the traffic to the NetScaler CPX container hosted on the same host as app B, and then the traffic is forwarded to app B. A similar traffic path is followed when app A sends request to app B.

In this example, a NetScaler MPX is also deployed to allow traffic to the applications from the Internet through a global VIP. The traffic from the NetScaler MPX is received on the NetScaler CPX containers, which then distributes the traffic across the application containers.

The following diagram illustrates this topology with the configurations that need to be set for communication to happen.

The following table lists the IP addresses and ports that are configured on the NetScaler CPX instances in this example configuration.

Docker Host 1		Docker Host 2		Docker Host 3	
VIPs	Services Bound to the VIP	VIPs	Services Bound to the VIP	VIPs	Services Bound to the VIP
VIP-A1 172.17.0.2:30000	SVC-A1 10.102.29.100:80	VIP-A2 172.17.0.3:30000	SVC-A2 10.102.29.105:80	VIP-A3 172.17.0.4:30000	SVC-VIP-A1 10.102.29.100:30000
					SVC-VIP-A2 10.102.29.105:30000
VIP-B1 172.17.0.2:30001	SVC-B1 10.102.29.100:90	VIP-B2 172.17.0.3:30001	SVC-VIP-B1 10.102.29.100:30001	VIP-B3 172.17.0.4:30001	SVC-VIP-B1 10.102.29.100:30001
VIP-C1 172.17.0.2:30002	SVC-VIP-C2 10.102.29.105:30002	VIP-C2 172.17.0.3:70	SVC-C2 10.102.29.105:70	VIP-C3 172.17.0.4:70	SVC-C3 10.102.29.110:70
	SVC-VIP-C3 10.102.29.110:30002				

To configure this example scenario, run the following command at the Linux shell prompt while creating the NetScaler CPX container on all three Docker hosts:

```
1 docker run -dt -p 22 -p 80 -p 161/udp -p 30000-30002: 30000-30002 --
  ulimit core=-1 --privileged=true cpx:6.2
2 <!--NeedCopy-->
```

Run the following commands either by using the Jobs feature in NetScaler ADM or by using NITRO APIs.

On NetScaler CPX instance on Docker Host 1:

```
1 add lb vserver VIP-A1 HTTP 172.17.0.2 30000
2 add service svc-A1 10.102.29.100 HTTP 80
3 bind lb vserver VIP-A1 svc-A1
4 add lb vserver VIP-B1 HTTP 172.17.0.2 30001
5 add service svc-B1 10.102.29.100 HTTP 90
6 bind lb vserver VIP-B1 svc-B1
7 add lb vserver VIP-C1 HTTP 172.17.0.2 30002
8 add service svc-VIP-C2 10.102.29.105 HTTP 30002
9 add service svc-VIP-C3 10.102.29.110 HTTP 30002
10 bind lb vserver VIP-C1 svc-VIP-C2
11 bind lb vserver VIP-C1 svc-VIP-C3
12 <!--NeedCopy-->
```

On the NetScaler CPX instance on Docker host 2:

```
1 add lb vserver VIP-A2 HTTP 172.17.0.3 30000
2 add service svc-A2 10.102.29.105 HTTP 80
3 bind lb vserver VIP-A2 svc-A2
4 add lb vserver VIP-B2 HTTP 172.17.0.3 30001
5 add service svc-VIP-B1 10.102.29.100 HTTP 30001
6 bind lb vserver VIP-B2 svc-VIP-B1
7 add lb vserver VIP-C2 HTTP 172.17.0.3 30002
8 add service svc-C2 10.102.29.105 HTTP 70
9 bind lb vserver VIP-C2 svc-C2
10 <!--NeedCopy-->
```

On the NetScaler CPX instance on Docker host 3:

```
1 add lb vserver VIP-A3 HTTP 172.17.0.4 30000
2 add service svc-VIP-A1 10.102.29.100 HTTP 30000
3 add service svc-VIP-A2 10.102.29.105 HTTP 30000
4 bind lb vserver VIP-A3 svc-VIP-A1
5 bind lb vserver VIP-A3 svc-VIP-A2
6 add lb vserver VIP-B3 HTTP 172.17.0.4 30001
7 add service svc-VIP-B1 10.102.29.100 HTTP 30001
8 bind lb vserver VIP-B3 svc-VIP-B1
9 add lb vserver VIP-C3 HTTP 172.17.0.4 30002
10 add service svc-C3 10.102.29.110 HTTP 70
11 bind lb vserver VIP-C3 svc-C3
12 <!--NeedCopy-->
```

Deploy NetScaler CPX in a Single Host Network

October 17, 2023

In a single host network, the NetScaler CPX instance acts as a proxy between application containers on the same host. In this capacity, the NetScaler CPX instance provides scalability and security to the container-based applications. Additionally, it optimizes performance and also provides an insight into telemetry data.

In a single host network, the client, the servers, and the NetScaler CPX instance are deployed as containers on the same Docker host. All the containers are connected through docker0 bridge.

In this environment, the NetScaler CPX instance acts as a proxy for the applications provisioned as containers on the same Docker host.

The following figure illustrates the single host topology.

In this example, a web app container (172.17.0.2) is the client and the two database containers, DB1 (172.17.0.10) and DB2 (172.17.0.11), are the servers. The NetScaler CPX container (172.17.0.4) sits between the client and the servers acting as a proxy.

To enable the web application to communicate with the database containers through NetScaler CPX, you have to first configure two services on the NetScaler CPX container to represent the two servers. Then, configure a virtual server by using the NetScaler CPX IP address and a non-standard HTTP port (such as 81) because the NetScaler CPX reserves the standard HTTP port 80 for NITRO communication.

In this topology, you do not have to configure any NAT rules because the client and the server are on the same network.

To configure this scenario, run the following commands either by using the Jobs feature in NetScaler ADM or by using NITRO APIs:

```
1      add service db1 HTTP 172.17.0.10 80
2      add service db2 HTTP 172.17.0.11 80
3      add lb vserver cpx-vip HTTP 172.17.0.4 81
4      bind lb vserver cpx-vip db1
5      bind lb vserver cpx-vip db2
6      <!--NeedCopy-->
```

Deploy NetScaler CPX in a Multi-Host Network

November 2, 2023

A NetScaler CPX instance in a multi-host network may be configured in a production deployment in the datacenter where it provides load balancing functions. It can further provide monitoring functions and analytics data.

In a multi-host network, the NetScaler CPX instances, backend servers, and the clients are deployed on different hosts. You can use multi-host topologies in production deployments where the NetScaler CPX instance load balances a set of container-based applications and servers or even physical servers.

Topology 1: NetScaler CPX and Backend Servers on Same Host; Client on a Different Network

In this topology, the NetScaler CPX instance and the database servers are provisioned on the same Docker host, but the client traffic originates from elsewhere on the network. This topology might be used in a production deployment where the NetScaler CPX instance load balances a set of container-based applications or servers.

The following diagram illustrates this topology.

In this example, the NetScaler CPX instance (172.17.0.4) and the two servers, DB1 (172.17.0.10) and DB2 (172.17.0.11) are provisioned on the same Docker host with IP address 10.102.29.100. The client resides elsewhere on the network.

The client requests originating from the Internet are received on the VIP configured on the NetScaler CPX instance, which then distributes the requests across the two servers.

There are two methods you can use to configure this topology:

Method 1: Using an additional IP address and standard port for the VIP

1. Configure the VIP on the NetScaler CPX container by using an additional IP address.
2. Configure an additional IP address for the Docker host.
3. Configure NAT rules to forward all traffic received on the Docker host's additional IP address to the VIP's additional IP address.
4. Configure the two servers as services on the NetScaler CPX instance.
5. Finally, bind the services to the VIP.

Note that in this example configuration, the 10.x.x.x network denotes a public network.

To configure this example scenario, run the following commands either by using the Jobs feature in NetScaler ADM or by using NITRO APIs:

```
1 add service s1 172.17.0.10 HTTP 80
```

```
2      add service s2 172.17.0.11 HTTP 80
3      add lb vserver cpx-vip HTTP 172.17.4.100 80
4      bind lb vserver cpx-vip s1
5      bind lb vserver cpx-vip s2
6 <!--NeedCopy-->
```

Configure an additional public IP address for the Docker host and a NAT rule by running the following commands at the Linux shell prompt:

```
1      ip addr add 10.102.29.103/24 dev eth0
2      iptables -t nat -A PREROUTING -p ip -d 10.102.29.103 -j DNAT --to-
      destination 172.17.4.100
3 <!--NeedCopy-->
```

Method 2: Using the NetScaler CPX IP address for the VIP and by configuring port mapping:

1. Configure the VIP and the two services on the NetScaler CPX instance. Use a non-standard port, 81, with the VIP.
2. Bind the services to the VIP.
3. Configure a NAT rule to forward all traffic received on port 50000 of the Docker host to the VIP and port 81.

To configure this example scenario, run the following command at the Linux shell prompt while creating the NetScaler CPX container on all three Docker hosts:

```
1      docker run -dt -p 22 -p 80 -p 161/udp -p 50000:81 --ulimit core=-1
      --privileged=true cpx:6.2
2
3 <!--NeedCopy-->
```

After the NetScaler CPX instance is provisioned, run the following commands either by using the Jobs feature in NetScaler ADM or by using NITRO APIs:

```
1      add service s1 172.17.0.10 http 80
2      add service s2 172.17.0.11 http 80
3      add lb vserver cpx-vip HTTP 172.17.0.4 81
4      bind lb vserver cpx-vip s1
5      bind lb vserver cpx-vip s2
6 <!--NeedCopy-->
```

Note:

If you have not configured port mapping during provisioning of the NetScaler CPX instance, then configure a NAT rule by running the following commands at the Linux shell prompt:

```
iptables -t nat -A PREROUTING -p tcp -m addrtype --dst-type LOCAL -m tcp --dport 50000 -j
DNAT --to-destination 172.17.0.4:81
```

Topology 2: NetScaler CPX with Physical Servers and Client

In this topology, only the NetScaler CPX instance is provisioned on a Docker host. The client and the servers are not container-based and reside elsewhere on the network.

In this environment, you can configure the NetScaler CPX instance to load balance traffic across the physical servers.

The following figure illustrates this topology.

In this example, the NetScaler CPX container (172.17.0.4) sits between the client and the physical servers acting as a proxy. The servers, DB1 (10.102.29.105) and DB2 (10.102.29.110), reside outside a Docker host on the network. The client request originates from the Internet and is received on the NetScaler CPX, which distributes it across the two servers.

To enable this communication between the client and the servers through NetScaler CPX, you have to first configure port mapping while creating the NetScaler CPX container. Then, configure the two services on the NetScaler CPX container to represent the two servers. And finally, configure a virtual server by using the NetScaler CPX IP address and the non-standard mapped HTTP port 8080.

Note that in the example configuration, the 10.x.x.x network denotes a public network.

To configure this example scenario, run the following command at the Linux shell prompt while creating the NetScaler CPX container:

```

1     docker run -dt -p 22 -p 80 -p 161/udp -p 8080:8080 --ulimit core=-1
      --privileged=true cpx:6.2
2 <!--NeedCopy-->

```

Then, run the following commands either by using the Jobs feature in NetScaler ADM or by using NITRO APIs:

```

1     add service s1 HTTP 10.102.29.105 80
2     add service s2 HTTP 10.102.29.110 80
3     add lb vserver cpx-vip HTTP 172.17.0.4 8080
4     bind lb vserver cpx-vip s1
5     bind lb vserver cpx-vip s2
6 <!--NeedCopy-->

```

Topology 3: NetScaler CPX and Servers Provisioned on Different Hosts

In this topology, the NetScaler CPX instance and the database servers are provisioned in different Docker hosts, and the client traffic originates from the Internet. This topology might be used in a production deployment where the NetScaler CPX instance load balances a set of container-based applications or servers.

The following diagram illustrates this topology.

In this example, the NetScaler CPX instance and a server (DB1) are provisioned on the same Docker host with IP address 10.102.29.100. Four other servers (DB2, DB3, DB4, and DB5) are provisioned on two different Docker hosts, 10.102.29.105 and 10.102.29.110.

The client requests originating from the Internet are received on the NetScaler CPX instance, which then distributes the requests across the five servers. To enable this communication, you must configure the following:

1. Set port mapping while creating your NetScaler CPX container. In this example, this means that you have to forward port 8080 on the container to port 8080 on the host. When the client request arrives on port 8080 of the host, it maps to port 8080 of the CPX container.
2. Configure the five servers as services on the NetScaler CPX instance. You have to use a combination of the respective Docker host IP address and mapped port to set these services.
3. Configure a VIP on the NetScaler CPX instance to receive the client request. This VIP should be represented by the NetScaler CPX IP address and port 8080 that was mapped to port 8080 of the host.
4. Finally, bind the services to the VIP.

Note that in the example configuration, the 10.x.x.x network denotes a public network.

To configure this example scenario, run the following command at the Linux shell prompt while creating the NetScaler CPX container:

```
1    docker run -dt -p 22 -p 80 -p 161/udp -p 8080:8080 --ulimit core=-1
    --privileged=true cpx:6.2
2    <!--NeedCopy-->
```

Run the following commands either by using the Jobs feature in NetScaler ADM or by using NITRO APIs:

```
1    add service s1 10.102.29.100 HTTP 8081
2    add service s2 10.102.29.105 HTTP 8081
3    add service s3 10.102.29.105 HTTP 8082
4    add service s4 10.102.29.110 HTTP 8081
5    add service s5 10.102.29.110 HTTP 8082
6    add lb vserver cpx-vip HTTP 172.17.0.2 8080
7    bind lb vserver cpx-vip s1
8    bind lb vserver cpx-vip s2
9    bind lb vserver cpx-vip s3
10   bind lb vserver cpx-vip s4
11   bind lb vserver cpx-vip s5
12   <!--NeedCopy-->
```

Deploy NetScaler CPX with direct access to the network

October 17, 2023

In bridge networking mode, you can configure NetScaler CPX instance to have direct access to the network. In this scenario, the incoming traffic is directly received on the NetScaler CPX virtual server IP (VIP).

To enable this communication, you have to first configure a public IP address on docker0 bridge. Then, remove the public IP address from the network port eth0 and bind the network port to the docker0 bridge.

Configure load balancing by adding the two services and then configure a network public IP address as the VIP on the NetScaler CPX instance. The client requests are received directly on the VIP.

In the example configuration, the 10.x.x.x network denotes a public network.

To configure this scenario, run the following command at the Linux shell prompt:

```
1 ip addr add 10.102.29.100/24 dev docker0;
2 ip addr del 10.102.29.100/24 dev eth0;
3 brctl addif docker0 eth0;
4 ip route del default;
5 ip route add default via 10.102.29.1 dev docker0
6 <!--NeedCopy-->
```

Either by using the Jobs feature in NetScaler ADM or by using NITRO APIs, run the following commands:

```
1 add service s1 172.17.0.8 http 80
2 add service s2 172.17.0.9 http 80
3 add lb vserver cpx-vip HTTP 10.102.29.102 80
4 bind lb vserver cpx-vip s1
5 bind lb vserver cpx-vip s2
6 <!--NeedCopy-->
```

Configure NetScaler CPX in Kubernetes Using ConfigMaps

October 17, 2023

In Kubernetes, you can configure the NetScaler CPX instance using ConfigMaps. Using ConfigMaps you can dynamically configure the NetScaler CPX instance during instance startup.

Create a `cpx.conf` configuration file that includes NetScaler-specific configuration and bash shell commands that you want to run dynamically on the NetScaler CPX instance. The configuration file

structure requires two types of tags, `#NetScaler Commands` and `#Shell Commands`. Under the `#NetScaler Commands` tag, you must add all the NetScaler commands to configure NetScaler-specific configuration on NetScaler CPX instance. Under the `#Shell Commands` tag, you must add the shell commands that you want to run on the NetScaler CPX instance.

Important:

- The tags can be repeated multiple times in the configuration file.
- The configuration file can also include comments. Add a “#” character before comments.
- The tags are not case-sensitive.
- If there are failure scenarios while deploying the NetScaler CPX container with the configuration file, the failures are logged in the `ns.log` file.
- After the NetScaler CPX instance starts, if you change the ConfigMap, the updated configuration is applied only when the NetScaler CPX instance is restarted.

The following is a sample configuration file:

```
1 #NetScaler Commands
2 add lb vserver v1 http 1.1.1.1 80
3 add service s1 2.2.2.2 http 80
4 bind lb vserver v1 s1
5 #Shell Commands
6 touch /etc/a.txt
7 echo "this is a" > /etc/a.txt
8 #NetScaler Commands
9 add lb vserver v2 http
10 #Shell Commands
11 echo "this is a 1" >> /etc/a.txt
12 #NetScaler Commands
13 add lb vserver v3 http
14 <!--NeedCopy-->
```

Once you have created the configuration file, you must create a ConfigMap from the configuration file using the `kubectl create configmap` command.

```
1 kubectl create configmap cpx-config --from-file=cpx.conf
2 <!--NeedCopy-->
```

In the example above, you can create a ConfigMap, `cpx-config` based on the configuration file `cpx.conf`. You can then use this ConfigMap in the YAML file used to deploy the NetScaler CPX instance.

You can view the created ConfigMap using the `kubectl get configmap` command.

```
root@node1:~/yaml# kubectl get configmap cpx-config -o yaml
```

Sample:

```
1   apiVersion: v1
2   data:
```

```

3      cpx.conf: |
4      #NetScaler Commands
5          add lb vserver v1 http 1.1.1.1 80
6          add service s1 2.2.2.2 http 80
7          bind lb vserver v1 s1
8      #Shell Commands
9          touch /etc/a.txt
10         echo "this is a" > /etc/a.txt
11         echo "this is the file" >> /etc/a.txt
12         ls >> /etc/a.txt
13     #NetScaler Commands
14         add lb vserver v2 http
15     #Shell Commands
16         echo "this is a 1" >> /etc/a.txt
17     #NetScaler Commands
18         add lb vserver v3 http
19     #end of file
20     kind: ConfigMap
21     metadata:
22         creationTimestamp: 2017-12-26T06:26:50Z
23         name: cpx-config
24         namespace: default
25         resourceVersion: "8865149"
26         selfLink: /api/v1/namespaces/default/configmaps/cpx-config
27         uid: c1c7cb5b-ea05-11e7-914a-926745c10b02
28     <!--NeedCopy-->

```

You can specify the created ConfigMap, `cpx-config` in the YAML file used to deploy the NetScaler CPX instance as follows:

```

1  apiVersion: v1
2  kind: Pod
3  metadata:
4    name: cpx-1
5    labels:
6      app: cpx-daemon
7    annotations:
8      NETSCALER_AS_APP: "True"
9  spec:
10   hostNetwork: true
11   containers:
12   - name: cpx
13     image: "quay.io/citrix/citrix-k8s-cpx-ingress:13.1-33.47"
14     securityContext:

42 <!--NeedCopy-->
```

Once the NetScaler CPX is instance is deployed and starts the configuration specified in the ConfigMap, `cpx-config` is applied to the NetScaler CPX instance.

Deploy NetScaler CPXs as Local DNS Caches for Kubernetes Nodes

October 17, 2023

Application pods in a Kubernetes cluster rely on DNS to communicate with other application pods. DNS requests from applications inside a Kubernetes cluster are handled by Kubernetes DNS (kube-dns). Due to wider adoption of microservices architectures, DNS request rates inside a Kubernetes cluster are increasing. As a result, Kubernetes DNS (kube-dns) is overburdened. Now you can deploy NetScaler CPX as a local DNS cache on each Kubernetes node and forward DNS requests from application pods in the node to NetScaler CPX. Hence, you can resolve DNS requests faster and significantly reduce the load on Kubernetes DNS.

To deploy NetScaler CPXs, a Kubernetes DaemonSet entity is used to schedule NetScaler CPX pods on each node in the Kubernetes cluster. A Kubernetes DaemonSet ensures that there is an instance of NetScaler CPX on each Kubernetes node in the cluster.

To make application pods direct traffic to CPX DNS pods, you need to create a Kubernetes service with endpoints as NetScaler CPX pods. Cluster IP of this service is used as the DNS endpoint for the application pods. To make sure that the application pods use NetScaler CPX service cluster IP address for DNS resolution, you need to update the kubelet configuration file on each node with NetScaler CPX service cluster IP.

The following environment variables are introduced to support the deployment of NetScaler CPX as NodeLocal DNS cache:

- **KUBE_DNS_SVC_IP**: Specifies the cluster IP address of the `kube-dns` service which is a mandatory argument to trigger the configuration on a NetScaler CPX pod. The NetScaler CPX pod directs DNS queries to this IP address when the DNS query response is not available in the NetScaler CPX cache.
- **CPX_DNS_SVC_IP**: Specifies the cluster IP address of the NetScaler CPX service. The `CPX_DNS_SVC_IP` environment variable is used to configure local DNS on nodes. When you configure this variable, an `iptables` rule is added to direct the DNS requests originating from application pods to the local NetScaler CPX pod inside the node.
- **NS_DNS_FORCE_TCP**: This environment variable forces using TCP for DNS requests even if the queries are received over UDP.
- **NS_DNS_EXT_RESLV_IP**: Specifies the IP address of the external name server to direct the DNS requests for a specific domain.
- **NS_DNS_MATCH_DOMAIN**: Specifies the external domain string to be matched against to direct the queries to the external name server.

Deploy NetScaler CPXs as DNS Caches on Nodes

Deploying NetScaler CPX as local DNS cache for a Kubernetes cluster includes the following tasks:

On the master node:

- Create a Kubernetes service with endpoints as NetScaler CPX pods
- Create a ConfigMap for defining environment variables for NetScaler CPX pods
- Schedule NetScaler CPX pods on each node in the Kubernetes cluster using a Kubernetes DaemonSet.

On worker nodes:

- Modify the kubelet configuration file with the cluster IP address of NetScaler CPX service to forward DNS requests to NetScaler CPXs.

Configuration on the Kubernetes Master Node

Perform the following steps on the Kubernetes master node to deploy NetScaler CPX as the local DNS cache for nodes:

1. Create a service with NetScaler CPX pods as endpoints using the `cpx_dns_svc.yaml` file.

```
1 kubectl apply -f cpx_dns_svc.yaml
```

The `cpx_dns_svc.yaml` file is provided as follows:

```
1     apiVersion: v1
2     kind: Service
3     metadata:
4       name: cpx-dns-svc
5       labels:
6         app: cpxd
7     spec:
8       ports:
9         - protocol: UDP
10         port: 53
11         name: dns
12         - protocol: TCP
13         port: 53
14         name: dns-tcp
15       selector:
16         app: cpx-daemon
```

2. Get the IP address of the NetScaler CPX service.

```
1 kubectl get svc cpx-dns-svc
```

3. Get the IP address of the Kube DNS service.

```
1 kubectl get svc -n kube-system
```

4. Create a ConfigMap for defining environment variables for NetScaler CPX pods. These environment variables are used to pass IP addresses of NetScaler CPX service and Kube DNS service. In this step, a sample ConfigMap `cpx-dns-cache` is created using the environment variables specified as data (key-value pairs) in a file.

```
1 kubectl create configmap cpx-dns-cache --from-file <path-to-file>
```

The following is a sample file with the environment variables as key-value pairs.

```
1 CPX_DNS_SVC_IP: 10.111.95.145
2 EULA: "yes"
3 KUBE_DNS_SVC_IP: 10.96.0.10
4 NS_CPX_LITE: "1"
5 NS_DNS_EXT_RESRV_IP: 10.102.217.142
6 NS_DNS_MATCH_DOMAIN: citrix.com
7 PLATFORM: CP1000
```

The following is a sample ConfigMap:

```
1 apiVersion: v1
2 data:
3   CPX_DNS_SVC_IP: 10.111.95.145
```

```
4  EULA: "yes"
5  KUBE_DNS_SVC_IP: 10.96.0.10
6  NS_CPX_LITE: "1"
7  NS_DNS_EXT_RESRV_IP: 10.102.217.142
8  NS_DNS_MATCH_DOMAIN: citrix.com
9  PLATFORM: CP1000
10 kind: ConfigMap
11 metadata:
12   creationTimestamp: "2019-10-15T07:45:54Z"
13   name: cpx-dns-cache
14   namespace: default
15   resourceVersion: "8026537"
16   selfLink: /api/v1/namespaces/default/configmaps/cpx-dns-cache
17   uid: 8d06f6ee-133b-4e1a-913c-9963cbf4f48
```

5. Create a Kubernetes DaemonSet for NetScaler CPX on the master node.

```
1  kubectl apply -f cpx_daemonset.yaml
```

The `cpx_daemonset.yaml` file is provided as follows:

```
1  apiVersion: apps/v1
2  kind: DaemonSet
3  metadata:
4    name: cpx-daemon
5    labels:
6      app: cpxd
7  spec:
8    selector:
9      matchLabels:
10       app: cpx-daemon
11  template:
12    metadata:
13      labels:
14       app: cpx-daemon
15    spec:
16      containers:
17      - name: cpxd
18        imagePullPolicy: IfNotPresent
19        image: localhost:5000/dev/cpx
20        volumeMounts:
21        - mountPath: /netns/default/
22          name: test-vol
23        ports:
24        - containerPort: 53
25      envFrom:
26      - configMapRef:
27        name: cpx-dns-cache
28      securityContext:
29        privileged: true
30        allowPrivilegeEscalation: true
31      capabilities:
32        add: ["NET_ADMIN"]
```

```
33     volumes:
34     -   name: test-vol
35         hostPath:
36         path: /proc/1/ns
37         type: Directory
```

Configuration on Worker Nodes in the Kubernetes Cluster

Once you complete configuration on master node, perform the following step on worker nodes:

1. Modify the kubelet configuration file so that application pods can use NetScaler CPX service cluster IP for DNS resolution using one of the following steps:
 - Follow the steps in [reconfigure a Node's kubelet](#) and modify the `--cluster-dns` argument value in the following format.

```
1     --cluster-dns=<CPX_DNS_SVC_IP>,<KUBE_DNS_SVC_IP>
```

or

- Edit the `/etc/systemd/system/kubelet.service.d/10-kubeadm.conf` file and modify the `--cluster-dns` argument using the following steps.
 - a) Edit the kubelet configuration and specify the cluster IP address of NetScaler CPX service and `kube-dns` service IP address for the `--cluster-dns` argument.

```
1  root@node:~# cat /etc/systemd/system/kubelet.service.d/10-
    kubeadm.conf | grep KUBELET\_DNS\_ARGS
2
3  Environment="KUBELET_DNS_ARGS=--cluster-dns
    =10.111.95.145,10.96.0.10 --cluster-domain=cluster.
    local"
4  ExecStart=/usr/bin/kubelet $KUBELET_KUBECONFIG_ARGS
    $KUBELET_CONFIG_ARGS $KUBELET_DNS_ARGS
```

- b) Reload the kubelet of nodes using the following commands:

```
1  # systemctl daemon-reload
2  # service kubelet restart
```

Deploy NetScaler CPX Proxy on Google Compute Engine

November 2, 2023

This deployment guide describes how you can deploy NetScaler CPX with Docker on Google Cloud's Google Compute Engine (GCE) with NetScaler ADM running within the enterprise network. In this

deployment, NetScaler CPX installed on GCE load balances two back-end servers, and NetScaler ADM provides licensing and analytics solutions.

NetScaler CPX is a container-based proxy that supports full Layer 7 functionality, SSL offload, multiple protocols, and NITRO API. NetScaler ADM provides management, licensing, and analytics solutions. As a licensing server, NetScaler ADM provides entitlement to NetScaler CPX instances that run on premises or in the cloud.

CPX and CPX Express are the same images. When you license and install the CPX image using NetScaler ADM, the CPX image in the Docker App Store (release 11 or 12) becomes a full CPX instance. Without a license, the CPX image becomes a CPX Express instance supporting 20 Mbps and 250 SSL connections.

Prerequisites

- 2 GB of memory and 1 vCPU dedicated to NetScaler CPX
- Docker open source available from GCE
- NetScaler ADM running on premises with internet or VPN connection to GCE

Note

For information about how to deploy NetScaler ADM see [Deploying NetScaler ADM](#).

Configuration Steps

You have to perform the following steps to configure this deployment.

1. Install Docker on a GCE VM.
2. Configure Remote API Communication with the Docker Instance.
3. Install NetScaler CPX image.
4. Create a CPX instance.
5. License NetScaler CPX through NetScaler ADM.
6. Configure Load Balancing Services on NetScaler CPX and verify the configuration.
 - a) Install NGINX web servers.
 - b) Configure NetScaler CPX for load balancing and verify distribution of load to both web services.

Step 1: Install Docker on a GCE VM

From GCE, create a Linux Ubuntu VM. Then, install Docker on the VM by using the commands shown in the following example:

```

1 $ sudo curl -ssl https://get.docker.com/ | sh
2 % Total % Received % Xferd Average Speed Time Time Time Current
3 Dload Upload Total Spent Left Speed
4 0 0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0curl: (6) Could not resolve
   host: xn--ssl-1n0a
5 100 17409 100 17409 0 0 21510 0 --:--:-- --:--:-- --:--:-- 21492
6 apparmor is enabled in the kernel and apparmor utils were already
   installed

128 API version: 1.29
129 Go version: go1.7.5
130 Git commit: 89658be
131 Built: Thu May 4 22:15:36 2017
132 OS/Arch: linux/amd64
133
134 Server:
135 Version: 17.05.0-ce
136 API version: 1.29 (minimum version 1.12)
137 Go version: go1.7.5
138 Git commit: 89658be
139 Built: Thu May 4 22:15:36 2017
140 OS/Arch: linux/amd64
141 Experimental: false
142
143 If you would like to use Docker as a non-root user, you should now
    consider
144 adding your user to the "docker" group with something like:
145
146 sudo usermod -aG docker albert\_lee
147
148 Remember that you will have to log out and back in for this to take
    effect.
149
150 WARNING: Adding a user to the "docker" group will grant the ability to
    run
151 containers which can be used to obtain root privileges on the
152 docker host.
153 Refer to https://docs.docker.com/engine/security/security/#docker-
    daemon-attack-surface
154 for more information.

Step 3: Install NetScaler CPX Image

Get the NetScaler CPX image from Docker App Store. The CPX Express and CPX have the same image. But, when you license and install the CPX image using NetScaler ADM the image becomes a full CPX instance with 1 Gbps of performance. Without a license, the image becomes a CPX Express instance supporting 20 Mbps and 250 SSL connections.

```
1 $ **sudo docker pull store/citrix/citrixadccpx:13.0-36.29**

Step 5: License NetScaler CPX Through NetScaler ADM

Assuming NetScaler ADM is running on premises, you should be able to validate that NetScaler CPX is communicating with NetScaler ADM and sending information. The following images show NetScaler CPX retrieving a license from NetScaler ADM.

Networks > License Settings

License Server Port Settings

Proxy Server Port	License Server Port	Vendor Daemon Port
0	27000	7279

License Files

The following license files are present on this server. Select **Add New License** to upload more licenses. To delete a license, select the license and click **Delete**.

NetScaler CPX troubleshooting

October 17, 2023

This document explains how to troubleshoot issues that you may encounter while using NetScaler CPX. Using this document, you can collect logs to determine the causes and apply workarounds for some of the common issues related to the installation and configuration of NetScaler CPX.

- How can I view NetScaler CPX logs?

You can view NetScaler CPX logs using the `kubectl logs` command if NetScaler CPX is deployed with the `tty:true` option. You can run the following command to display the logs:

```
1 kubectl logs <pod-name> [-c <container-name>] [-n <namespace-name>]
```

Example,

```
1 kubectl logs cpx-ingress1-69b9b8c648-t8bgn -c cpx -n citrix-adc
```

The following is an example of the NetScaler CPX pod deployment with the `tty:true` option:

```

1   containers:
2     - name: cpx-ingress
3       image: "quay.io/citrix/citrix-k8s-cpx-ingress:13.0-58.30"
4       tty: true
5       securityContext:
6         privileged: true
7       env:
8
9   <!--NeedCopy-->

```

You can find more boot logs in the `/cpx/log/boot.log` file of NetScaler CPX file system.

Note: To get the pod name, run the `kubectl get pods -o wide` command.

- How can I collect the technical support bundle from NetScaler CPX?

You can run the following command on the shell interface of the Kubernetes master node to collect the NetScaler CPX technical support bundle:

```

1   kubectl exec <cpx-pod-name> [-c <cpx-container-name>] [-n <
    namespace-name>] /var/netScaler/bins/cli_script.sh "show
    techsupport"

```

You can view the technical support bundle in the `/var/tmp/support` directory of the NetScaler CPX's file system. Use `scp` or `kubectl cp` to copy the technical support bundle from NetScaler CPX to the desired destination.

Example:

```

1   root@localhost# kubectl exec cpx-ingress1-55b9b6fc75-t5kc6 -c cpx
    -n citrix-adc /var/netScaler/bins/cli_script.sh "show
    techsupport"
2   exec: show techsupport
3   Scope:  NODE
4   Done
5   root@localhost# kubectl cp cpx-ingress1-55b9b6fc75-t5kc6:var/tmp/
    support/collector_P_192.168.29.232_31Aug2020_07_30.tar.gz /tmp
    /collector_P_192.168.29.232_31Aug2020_07_30.tar.gz -c cpx
6   root@localhost# ll /tmp/collector_P_192.168.29.232
    _31Aug2020_07_30.tar.gz
7   -rw-r--r-- 1 root root 1648109 Aug 31 13:23 /tmp/collector_P_192
    .168.29.232_31Aug2020_07_30.tar.gz

```

- Why is NetScaler CPX pod stuck while booting?

You can check the pod status using the `kubectl describe pods` command. Run the following command to know the pod status:

```

1   kubectl describe pods <pod-name> [-c <container-name>] [-n <
    namespace-name>]

```

Example:

```
1 kubectl describe pods cpx-ingress1-69b9b8c648-t8bgn
```

If the pod events show that container is started, then you must check the pod logs.

- How do I copy files between the NetScaler CPX pod and the Kubernetes master node?

It is recommended to use the volume mount feature of docker to mount the `/cpx` directory to the file system of the host. If a NetScaler CPX container exits core-dumps, logs and other important data are available on the mount point.

You can use any one of the following commands to copy files between the NetScaler CPX pod and the Kubernetes master node:

kubectl cp: You can run the following command to copy files from pod to node:

```
1 kubectl cp <pod-name>:<absolute-src-path> <dst-path> [-c <
  container-name>] [-n <namespace-name>]
```

Example:

```
1 root@localhost:~# kubectl cp cpx-ingress-596d56bb6-zbx6h:cpx/log/
  boot.log /tmp/cpx-boot.log -c cpx-ingress
2 root@localhost:~# ll /tmp/cpx-boot.log
3 -rw-r--r-- 1 root root 7880 Sep 11 00:07 /tmp/cpx-boot.log
```

scp: You can use the command to copy files between the NetScaler CPX pod and the Kubernetes node. Run the following command to copy files from pod to node. When it prompts for the password, provide the password for the SSH user:

```
1 scp <user>@<pod-ip>:<absolute-src-path> <dst-path>
```

Example:

```
1 root@localhost:~# scp nsroot@192.168.29.198:/cpx/log/boot.log /
  tmp/cpx-boot.log
2 nsroot@192.168.29.198's password:
3 boot.log
4 100% 7880      5.1MB/s   00:00
5 root@localhost:~#
```

- How do I capture packets on NetScaler CPX?

To capture packets on NetScaler CPX, launch the shell interface of NetScaler CPX using the `kubectl exec` command. Run the following command to launch the shell interface of the NetScaler CPX pod:

```
1 kubectl exec -it pod-name [-c container-name] [-n namespace-
  name] bash
```

Example:

```
1 kubectl exec -it cpx-ingress1-69b9b8c648-t8bgn -c cpx -n citrix-adc bash
```

And, run the following command to begin packet capture:

```
1 cli_script.sh "start nstrace -size 0"
```

If you want to stop the ongoing packet capture, run the following command:

```
1 cli_script.sh "stop nstrace"
```

You can view the packets captured in a *.cap* file in the */cpx/nstrace/time-stamp* directory on the NetScaler CPX file system.

- Why is the license server not configured even when NetScaler CPX is deployed with the `LS_IP=<ADM-IP>` environment variable?

Ensure that the license server is accessible from the node on which NetScaler CPX is deployed. You can use the `ping <ADM-IP>` command to verify the connectivity from the NetScaler CPX node to NetScaler ADM.

If NetScaler ADM is accessible from the node, then you must verify the license server configuration logs in the */cpx/log/boot.log* file. You can also check for license server configuration using the following command on the shell interface of the NetScaler CPX pod:

```
1 cli_script.sh "show licenseserver"
```

Example:

```
1 root@cpx-ingress-596d56bb6-zbx6h:/cpx/log# cli_script.sh "show licenseserver"
2 exec: show licenseserver
3 ServerName: 10.106.102.199Port: 27000 Status: 1 Grace: 0
  Gptimeleft: 720
4 Done
```

- Why is pooled license not configured on NetScaler CPX even after a successful license server configuration on NetScaler CPX?

Verify the license configuration logs in the */cpx/log/boot.log* file. You can also verify the configured pooled license on NetScaler CPX using the following command on the shell interface of the NetScaler CPX pod:

```
1 cli_script.sh "show capacity"
```

Example,

```
1 root@cpx-ingress-596d56bb6-zbx6h:/cpx/log# cli_script.sh "show capacity"
2 exec: show capacity
```

```

3 Actualbandwidth: 1000 MaxVcpuCount: 2 Edition: Platinum
  Unit: Mbps Bandwidth: 0` `Maxbandwidth: 40000
  Minbandwidth: 20 Instancecount: 1
4 Done

```

Also, ensure that the required license files are uploaded in the license server. You can also verify the available licenses on the license server once it is successfully configured on NetScaler CPX by using the following command. Run the command on the shell interface of NetScaler CPX pod:

```
1 cli_script.sh "sh licenseserverpool "
```

Example:

```

1 root@cpx-ingress-596d56bb6-zbx6h:/cpx/log# cli_script.sh "show
  licenseserverpool"
2 exec: show licenseserverpool
3 Instance Total : 5
4 Instance Available : 4
5 Standard Bandwidth Total : 0 Mbps
6 Standard Bandwidth Available : 0 Mbps
7 Enterprise Bandwidth Total : 0 Mbps
8 Enterprise Bandwidth Available : 0 Mbps
9 Platinum Bandwidth Total : 10.00 Gbps
10 Platinum Bandwidth Available : 9.99 Gbps
11 CP1000 Instance Total : 100
12 CP1000 Instance Available : 100
13 Done
14 <!--NeedCopy-->

```

- Why do NITRO API calls get *Connection Refused* response from NetScaler CPX?

The default port for NITRO APIs is 9080 (unsecure) and 9443 (secure) from the NetScaler CPX release 12.1 onwards. Ensure that the NITRO port of NetScaler CPX you try to access is exposed on the pod. You can run the `kubectl describe` command to view the exposed and mapped port of the NetScaler CPX container in the NetScaler CPX container section:

```
1 kubectl describe pods <pod-name> | grep -i port
```

Example:

```

1 ng472 | grep -i port
2 Ports: 80/TCP, 443/TCP, 9080/TCP, 9443/TCP
3 Host Ports: 0/TCP, 0/TCP, 0/TCP, 0/TCP
4 NS_HTTP_PORT: 9080
5 NS_HTTPS_PORT: 9443
6 Port: <none>
7 Host Port: <none>
8 NS_PORT: 80
9 <!--NeedCopy-->

```

- Why does the NSPPE process in NetScaler CPX consume most of the CPU usage even when there is no or little traffic?

If NetScaler CPX is deployed with the `CPX_CONFIG='{ "YIELD": "NO" }'` environment variable, the NSPPE process consumes 100 percent CPU usage even when there is no or little traffic. If you want the NSPPE process not to consume the CPU usage, you must deploy NetScaler CPX without the `CPX_CONFIG='{ "YIELD": "NO" }'` environment variable. By default, the NSPPE process in CPX is configured not to hog or consume the CPU usage.

- Why is NetScaler CPX not listed in NetScaler ADM even when it was deployed with the required environment variables for registration with NetScaler ADM?

You can find the logs for NetScaler CPX registration with NetScaler ADM in the `/cpx/log/boot.log` file on the NetScaler CPX file system.

You can verify the accessibility of the NetScaler ADM IP address from the NetScaler CPX pod using the `ping` command. Also, ensure that all the required environment variables for NetScaler ADM registration are configured for the NetScaler CPX container.

- `NS_MGMT_SERVER`: Specifies the ADM-IP address or FQDN.
 - `HOST`: Specifies the node IP address.
 - `NS_HTTP_PORT`: Specifies the mapped HTTP- port on node.
 - `NS_HTTPS_PORT`: Specifies the mapped HTTPS port on node.
 - `NS_SSH_PORT`: Specifies the mapped SSH port on node.
 - `NS_SNMP_PORT`: Specifies the mapped SNMP port on node.
 - `NS_ROUTABLE`: NetScaler CPX pod IP address is not routable from outside.
 - `NS_MGMT_USER`: Specifies the ADM username.
 - `NS_MGMT_PASS`: Specifies the ADM password.
- Why does `cli_script.sh` show *Invalid user name or password* error message after changing the password for nsroot user?

The command `cli_script.sh` is a wrapper utility for NSCLI on NetScaler CPX. It runs the first argument as command string or file path and the second argument is optional which is credentials. If the password for the nsroot user is changed, you need to provide credentials as the second argument to `cli_script.sh`. You can run the following command to run NSCLI with credentials:

```
1 cli_script.sh " <command> " " :<username>:<password> "
```

Example:

```
1 root@087a1e34642d:/# cli_script.sh "show ns ip"
2 exec: show ns ip
3
4 ERROR: Invalid username or password
```

```

5
6 root@087a1e34642d:/# cli_script.sh "show ns ip" ":nsroot:
  nsroot123"
7
8 exec: show ns ip
9
10 Ipaddress      Traffic Domain      Type      Mode
      Arp      Icmp      Vserver  State
11 -----
12 172.17.0.3      0
      Enabled Enabled  NA      Enabled NetScaler IP  Active
13 192.0.0.1      0
      Enabled Enabled  NA      Enabled SNIP          Active
14 Done

```

- Why does SSH to NetScaler CPX fail with `root` and `nsroot` user?

From 13.0-64.35 release onwards, NetScaler CPX generates a default password and updates it for SSH users - `root` and `nsroot`. If you have not changed the password manually, password for SSH users can be found in `/var/deviceinfo/random_id` on NetScaler CPX's file-system.
